without proper authority; and upon those also, who, as vendors of poisons, do not keep them safely under lock and key. In England the government realise a very considerable sum of money from the sale of stamps upon patent medicines. In France the tribunals inflict heavy fines upon those persons who sell, or treat disease with, secret remedies. It is not hard to say on which side is the greater share of wisdom: that in which the liberty is accorded to poison or be poisoned, according to individual fancy—in which disease is virtually looked upon by the legislature as an occurrence to be made the most of in a pecuniary point of view by any means whatever; or that which defends the helpless from the tricks of unprincipled men, and which in all medical questions looks upon the *salus populi* as being truly the *suprema lex.—Med. Gaz.*

THE PRIZE SYSTEM.

Assuredly, as we have often said, there is but one step from the sublime to the ridiculous, and here is a proof of it. There is something ineffably amusing in the comparison between these proceedings and the "exhibitions" so lavishly provided for scholars requiring educational condiments with us. It is only erasing "female idiots" and inserting "medical students," and we have a paragraph to suit the events of the day:—

A very interesting distribution of prizes has just taken place at the Salpêtrière, Paris, amongst the female idiots and epileptic patients under the care of Dr. Mitivié. These prizes were given to such of them as had been distinguished by cleanliness, industry, by the care they had taken of little children, &c. &c. There were prizes given to those who had excelled in gymnastics or dancing. The Director-in-Chief of the public charities of Paris was present, as well as all the patients belonging to this section of the hospital. A few of the women took their part in a little theatrical piece which had been written for the occasion, and no one unacquainted with the place would have suspected that the performance was being supported by the inmates of an asylum.—*Lancet.*

Who can object after that, or say that prizes may not develop latent medical instincts, while at the same time they are of such value as a means of convincing the incredulous that the study of medicine and surgery is a lucrative calling. We have been thinking that now, while so many "medical men" are at a loss for employment, it might prove a capital speculation for a few of them to return to their studies and secure some of the good things provided to bring grist to the new medical mills. A good prize, exhibition, or scholarship, is better than a bad dispensary: indeed the hint has been anticipated in practice, for the seven travellers on the royal road to medical erudition who lately "passed" through the Castle were all "medical men" before their applications for "exhibitionships."

A MEDICAL EVIL CORRECTED.

Messrs. Highley and Son *versus* Quack Publications.—The profession will be much gratified on being made acquainted with the important fact that Messrs. Highley and Son, the eminent medical publishers of Fleet-street, and booksellers to the Royal College of Surgeons of England, have declined the further publication of all homœopathic, hydropathic, and other works devoted to the advancement of quackery.—*Lancet.*

Messrs. Highley are entitled to our thanks for this correction of a very offensive practice. It remains for the members of our profession to display a similar feeling by withdrawing their books from notorious publishers of these voluminous quack advertisements, and in every way repudiating connexion with them. The time has arrived for simultaneous action in such matters and a resolute determination to treat confederates and comforters of delinquents as accessories.

To Correspondents.—Mr. Maybury's case in our next.

THE MEDICAL COMMISSIONER.

The appointment of Dr. Macdonnell appeared in yesterday's (Tuesday) *Gazette*. That of the Inspectors will now of course speedily follow.

MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

NEWRY BRANCH.

We have great pleasure in publishing the list of contributors to the society, just now received (together with the amount) from Dr. Erskine, the active secretary of the Newry Branch. The list is highly creditable to that town. We would wish the example set by Newry were imitated by other towns of equal or greater resources. Limerick, Waterford, Clonmel, Galway, Londonderry, Drogheda, Sligo, Kilkenny, Wexford, and other populous places, ought to have their local associations. Wherever such branches have been established, as in Belfast, Armagh, Cork, and Newry, they have been found to work most beneficially. They strengthen the hands of the parent society by greatly increasing the contributions, and they benefit the locality still more, as it is a rule of the society to bestow upon the applicants of each district at least as much as is received from it; and if the cases be urgent, a great deal more, out of the general fund, to which large additions are being made every year:—

Dr. Morrison	£1	1	0
Dr. Molloy	1	1	0
Dr. Davis	1	1	0
Dr. Johnston	1	1	0
Dr. Starkey	1	1	0
Dr. Erskine	1	1	0
Surgeon Savage	1	1	0
Surgeon Black	1	1	0
Surgeon Woods	1	1	0
Surgeon Gray	1	1	0

M. W. HANLON, M.B.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS.

The Session 1851–52 commenced on Monday, October 27, at one o'clock.

Anatomy and Physiology—Dr. Jacob.
Descriptive Anatomy—Dr. Hart and Dr. Macdonnell.
Surgery—Mr. Porter and Mr. Hargrave.
Practice of Medicine—Dr. Benson.
Chemistry—Dr. Barker.
Midwifery—Dr. Beatty.
Comparative Anatomy—Dr. Jacob.
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. Labatt, Mr. T. D. Hargrave, Mr. Malcolmson, and Mr. J. Morgan.

Commencing May 3, by order of the College.

Materia Medica—Mr. Williams.
Medical Jurisprudence—Dr. Geoghegan.
Botany—Dr. A. Mitchell.
Practical Chemistry—Dr. Barker.

The Fee for each of the above Courses is Two Guineas, except Comparative Anatomy, which is free.

A Public Course of Lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session; and additional lectures on the same subject at intervals during the winter.

Practical Instruction in Operative Surgery is given by the Professors of Surgery, separate from the Surgical Lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the School of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for letters testimonial, unless issued in conformity with this regulation." Similar regulations have been adopted by the Council of the College of Surgeons of England.

In order to give full effect to this order, and to secure the advantages contemplated by it, no lectures will be delivered during the winter before one o'clock; from which hour the order of business will be as follows:—

Descriptive Anatomy, at twelve o'clock every day.
Anatomy and Physiology, at two o'clock every day.
Surgery, at three o'clock on Tuesdays, Thursdays, and Saturdays.
Chemistry, at one o'clock on Mondays, Wednesdays, and Fridays.
Practice of Medicine, at three o'clock on Mondays, Wednesdays, and Fridays.
Midwifery, at four o'clock on Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Anatomical Instruction on Mondays, from one to three o'clock, will consist of practical instruction in the use of the Microscope, Minute Dissections of Organic Structure, and the making of Anatomical Preparations.

The Professor of Botany will commence a course of Lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the Course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 27th.

During the summer recess this Hospital has been greatly enlarged. Its arrangements are now such as to afford the student an opportunity of studying disease in all its forms—medical and surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every student of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are also delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct Course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, and special wards are appropriated for the reception of Eye cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's Course of Lectures upon Military Surgery is also open to the pupils of the hospital. This Course is recognized in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments.

A Lending Library of well chosen books has been provided for the use of the pupils; and a correct registry of the cases in hospital is kept by the house-surgeon, to which they have free excess.

Certificates of attendance at this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	... ...	Six guineas.
,, Summer six months	...	Four guineas.
,, Nine months	... ...	Eight guineas.

Physicians and Surgeons.

A. Jacob, M.D., F.R.C.S., Professor of Anatomy and Physiology, Royal College of Surgeons.
T. E. Beatty, M.D., F.R.C.S., Professor of Midwifery, Royal College of Surgeons.
C. Benson, M.D., F.R.C.S., Professor of the Practice of Medicine, Royal College of Surgeons.
W. Hargrave, M.D., F.R.C.S., Professor of Surgery, Royal College of Surgeons.
R. C. Williams, M.D., F.R.C.S., Professor of Materia Medica, Royal College of Surgeons.
T. G. Geoghegan, M.D., F.R.C.S., Professor of Forensic Medicine, Royal College of Surgeons.
J. Tufnell, Esq., F.R.C.S., Surgeon to the Military Prison.

Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, 34, York-street.

PRACTICE OF PHYSIC.

Dr. Benson will commence the Course of Lectures on the Principles and Practice of Physic in the Royal College of Surgeons on Friday, the 7th day of November, at three o'clock p.m.

The Description, Pathology, Diagnosis, and Treatment of *Medical* Diseases will form the subject of the Course.

Pathological preparations, plates, and recent specimens of diseased parts, will be exhibited for the purpose of illustration.

The Lectures will be delivered on Mondays, Wednesdays, and Fridays throughout the session, at three o'clock.

N.B.—Gentlemen entering the Army are required to attend Two Courses of Lectures on the Practice of Medicine; and those entering the Navy to attend Three such Courses.

Fee for each Course ... ... Two guineas.

CORK SCHOOL OF MEDICINE.

The Twenty-fifth Winter Session commenced on the 20th of October, 1851.

Anatomy and Physiology—H. A. Cæsar, M.D.
Surgery—W. K. Tanner, M.D.
Materia Medica—J. F. McEvers, M.D.
Botany—T. Power, M.D.
Midwifery—W. C. Townsend, M.D.
Practice of Medicine—C. Armstrong, M.D.
Chemistry and Practical Chemistry—C. Nash, M.D.
Natural History—T. C. Shinkwin, M.R.C.S.
Natural Philosophy—E. McCarthy, Esq.
Practical Anatomy and Dissections—H. A. Cæsar, M.D. and T. C. Shinkwin, M.R.C.S.

This School, situate on the South Mall, *midway between the North and South Infirmaries*, possesses all the requisites for a complete system of medical education. Its reputation for a quarter of a century is best tested by the high character of its numerous "Alumni," not only in this city and province, but each department of her Majesty's service, and every quarter of the globe.

☞ Dr. Cæsar would receive a young Gentleman as indoor Apprentice, who would enjoy all the advantages of a comfortable and respectable home, salutary supervision, and professional education, rarely exceeded.

For particulars apply to Dr. Cæsar, South Mall.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

Extracts and Editorial Note from the New York Journal of Medicine.

"March 1, 1850.

"Brown's Cantharidine Tissue.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the Medical Examiner and Record of Medical Science for May, 1850, *published in Philadelphia.*

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"Andrew Smith, M.D.,
"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,
"Handsworth, Birmingham."

Sole by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

GUBAVENY DISPENSARY, COUNTY CAVAN.

At a General Meeting of the Subscribers, held by requisition in the Petty Sessions' House, at Killyglasson, on Thursday, the 30th of October,

Rev. Hugh DeLacy, P.P., in the chair,

it was proposed by Wm. Johnston, Esq. (agent to the Doobally estate), seconded by Wm. Nixon, Esq., and carried by acclamation,—That the following Address be presented to Alexander Flood, Esq., M.D.:—

We, the Subscribers to the Gubaveny Dispensary, are desirous of expressing in the strongest manner our high estimation of your medical skill and the very humane manner in which you have attended the sick and afflicted in this very extensive and mountainous district during a period of five years—a period teeming with famine, fever, and other epidemic maladies in this much neglected poor distressed parish. We avail ourselves of this pleasing opportunity (the last we may have as Subscribers to this Institution) of conjointly and individually expressing the very high respect and esteem in which we hold your professional abilities, and fondly hope that whatever change is about taking place, we and our poor people may still enjoy the benefit of your valuable medical services in this locality.

Signed, Hugh DeLacy, Chairman.
Andrew Moffitt, Secretary.

REPLY.

TO THE SUBSCRIBERS OF THE GUBAVENY DISPENSARY.

Gentlemen,—It is with no ordinary feelings of gratitude that I receive your very flattering and complimentary Address, but I fear those compliments are somewhat over-coloured through your kindness. However, I cannot but feel exceedingly gratified that my humble exertions, in my professional capacity, have met with your approbation while medical attendant of your dispensary during a period of five years. My humble exertions would have availed little were it not for your generous liberality in providing for the sick poor in this mountain district. Whatever labour I may have undergone in the discharge of my professional duty, I feel I have been amply compensated by your kind expressions.

I am sorry to say the connexion between us is soon to terminate. I beg to return you my most sincere and grateful thanks for the kind support and good feeling you always evinced towards me, and I trust that in the change that is about taking place, I may be permitted to enjoy the privilege of being your Medical Attendant.

I remain, gentlemen, your very humble and obedient servant, Alexander Flood.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

Bleeding, Cupping, the Application of Leeches, &c.

G. O. and Co. continue to be supplied with the Foreign Mineral Waters Fresh from their various Springs.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.
☞ *Change of Proprietorship.*
BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of
THE ROYAL MEDICAL HALL,
beg particularly to state, that henceforth
THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,
will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,
BEWLEY, OWEN, AND CO.'S ESTABLISHMENT
embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,
of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

RICHMOND LUNATIC ASYLUM.

A limited number of Pupils will be received at the above Institution. For particulars, apply to the Manager, at the Asylum.

November 10, 1851.

A TREATISE ON CATARACT;
Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.
By ARTHUR JACOB, M.D., F R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.
Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.
Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.
By WILLIAM HENRY PORTER, M.D.,
Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.
Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

ADVERTISEMENTS ADDRESSED TO THE MEDICAL PROFESSION.

THE Medical Directories for England, Ireland, and Scotland, published annually on January 1st, the only media through which that important section of the community can be successfully addressed by Advertisers. From the nature of their contents, every individual member is sure to refer to them; besides which, they are constantly appealed to by all classes in reference to matters connected with the Medical Profession. Advertisements intended for insertion must be sent early to Messrs. Thomas and Churchill, sole Agents for the Advertisement Department, Universal Advertising Offices, 19 to 21, Catherine-street, Strand, or to the office of the Directory, 4, Adam street, Adelphi.

Just published, fcap. 8vo, cloth, price 4s. 6d.,
ON THE PRESERVATION OF THE HEALTH OF WOMEN AT THE CRITICAL PERIODS OF LIFE.
By E. J. TILT, M.D.

"The volume now under notice is not, like too many others on similar topics, addressed to non-professional readers, but is specially adapted to the wants of medical practitioners. There is a large class of these, including the younger members of the profession, to whom the experience of a senior on the delicate and difficult subjects here treated, must be peculiarly acceptable. By a brief statement of the contents of Dr. Tilt's Essay, we shall afford our readers an opportunity of judging how far it may be regarded as deserving of their attention . . . . Our readers will, from the preceding sketch, be enabled to form an opinion as to whether this work deserves the character of utility which we are disposed to assign to it. We think that they will concur in our estimate thereof, which is, that presenting in a condensed form, in clear and elegant language, many very valuable facts in the history and pathology of menstruation, it will be found a useful treatise for consultation. We are satisfied that the Author has in no degree exaggerated the evils arising from a neglect of hygienic precautions; and he has not overstated the importance of a more vigilant attention to the preservation of the health of women."—*Medical Gazette.*

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A.

(Continued from p. 214.)

In my preceding communications I have endeavoured to lay before my readers, in as concise a form as appeared to me to be consistent with perspicuity, a brief outline of some of the general leading principles upon which I conceive there is evidence that organic creation has been constructed. The views I have ventured therein to advance being, as I believe, altogether distinct from those generally entertained upon the subject, while at the same time an acquaintance with those views being (as I regard it) indispensable to render intelligible my subsequent observations, I have found it to be unavoidable thus briefly to premise them. In doing so, it has been my effort so to express myself as to be intelligible to the least informed or least reflecting of my readers, and, by the form of phraseology adopted, to obviate any obscurity or doubt as to the meaning I was desirous of conveying. Aware of the tendency so doing has to embarrass the reader, it has been my study to avoid the introduction of *new terms* into my observations, and except in such instances as I felt that (consistently with the object of this series of papers) such could not be avoided, I have studiously refrained from so doing. The expression "*organizing atom*" and "*organized residual product*, I found it to be unavoidable to employ, inasmuch as without some such forms of expression I should be unable to convey to others the opinions I myself entertain. From the former of these expressions appearing to me to explain its own meaning, I have been induced to regard its adoption as desirable; and my meaning in the latter, as also my motive for its employment, I have endeavoured, by illustration and otherwise, to convey to the reader. Apprehensive, however, that with regard to either of these expressions (which are fundamental to the present inquiry), there may possibly to any of my readers have been either obscurity or ambiguity in the language in which I have endeavoured to convey myself, it has occurred to me that it might not perhaps be undesirable, before proceeding further with these observations, briefly to recapitulate what has been already advanced upon topics upon which it is essential that my readers should distinctly understand me. There is perhaps no way in which I could do so more clearly, more forcibly, and at the same time more concisely than by attempting to lay rapidly before the reader an outline of the striking analogy which I conceive may be recognized between certain of the general leading principles upon which the two great divisions of Nature appear to have been originally constructed—that is, the analogy (as regards their *constitution* and *the manner of their formation*) which, I conceive, may be recognized between the objects, respectively, of the inorganic and of the organized world, or of inert and of living creation. Before proceeding then to the application of the foregoing observations, I shall occupy very few moments in an effort to point out this analogy as a concise means of briefly recapitulating some of the leading points which have already been laid before the reader.

The globe we inhabit is, as my readers are aware, divided into two grand divisions or kingdoms, named inanimate and animate creation, or what we term an unorganized and an organized world. The former of these divisions, or the unorganized world, is, as my readers are further informed, composed, or as it were built up, of a limited number of what we term *distinct species* of mineral matter; to which species respectively (counting about sixty in all) have been given the names—carbon, oxygen, hydrogen, nitrogen, &c. Each of these distinct species of mineral matter has (as is well known to my readers) so been originally created or formed as that it shall comprise under it; or in other words, as that the entire species collectively shall consist of an incalculably vast number of inconceivably minute particles, which particles, from their supposed physical indivisibility, have been designated *mineral atoms*. By the union of such atoms in various forms of combination (in obedience to what we term their chemical and physical laws) has the inorganic world, as it now exists, been con-

structed. Thus, then, the vast, the almost countless forms or varieties of mineral matter which are found throughout inorganic creation, *have been formed by the union (in various forms of combination) of atoms of a comparatively limited number of distinct species of mineral matter.*

Such, my readers are aware, are the opinions now generally entertained as regards the constitution of the inanimate or unorganized world. Such, it is my opinion, is also the case as regards the constitution of the *animate* world, or world of organization. The same, in a word, I have endeavoured to show has also been Nature's arrangement in the construction or formation of *living* or *organizing* creation. It, too (as has been my effort to make apparent), is composed, or as it were built up, of a limited number of distinct species of *organizing* matter; and each of those species has (as I conceive, and have endeavoured to prove) been originally so constructed, or formed as *at present*, to comprise under it an incalculably vast number of microscopically minute granules, to which granules, in consequence of their physiological indivisibility, I have ventured to give the name *organizing atoms*.* Thus, then, the vast, the almost countless forms or varieties of *organizing* matter (that is, in other words, of *living beings)* found throughout organic or living creation, have (as it appears to me) been *formed by the union (in various forms of combination) of organizing atoms of a very limited number of distinct species of organizing matter.*

If such be the case (and reflection upon what has been already advanced will, I feel assured, convince the unprejudiced reader it is), may we not thus far at least recognize an analogy between the principles upon which Nature appears to have originally constructed the *elementary components* of the objects contained in the two great divisions of creation—namely, as all inanimate or mineral creation is reducible to minute particles termed inanimate or *mineral atoms*, so may all *living* or *organizing* creation be reduced to analogous particles, which may appropriately be termed *organizing atoms.*

Let us now inquire if this analogy can further be traced between the manner in which these elementary components (namely, ultimate *simple* atoms) unite to form *compound* matter in the two great divisions of Nature—that is, in

* I shall explain my motive for using the words "*at present*" in the above paragraph. Organic creation must obviously have had *a commencement*. What was that commencement? What was the condition of the organic world when the organization of inorganic matter *first commenced?* My readers will have the goodness to reflect on this question,—they will have the goodness to carry their imagination back to the period of the *first or earliest* appearance of an organic creation, and a moment's reflection will suffice to convince them that *some* vast distinction must necessarily exist between the condition of organic nature *at the period of its creation* and the condition of organic nature *at present*. A moment's reflection, I say, will suffice to convince them that some vast distinction there must obviously be between the constitution of the organic world, *at the first or earliest manifestation of organization*, at (if I may so term it) the *birth* of organic nature, and the constitution of that world after organization *has for centuries progressed*, after organic nature has passed through centuries of *development*. And what is that distinction? This is an important physiological inquiry; but does such inquiry admit of a rational reply? Supposing that we are familiar with the constitution of organic creation as *now* it exists, or in its present *advanced stage of development*, are we so circumstanced as to be enabled therefrom to collect *anything* as regards what must have been its constitution at the period when *first* it existed, or at the period (if I may so term it) of its *birth*? I conceive we are. I conceive that from an accurate acquaintance with the nature and constitution of the organic objects *now* before us, conjointly with a knowledge of the *manner in which those objects have been generated or formed*, we may collect much as to what must have been the nature and constitution of organic creation at the moment when the organization of an unorganized world first commenced.

I shall endeavour to point out to my readers what (as it appears to me) must have been *the nature* of the constitution of the organic world *at the period of its creation*, as also wherefore it is I am of opinion that such must have been the nature of its constitution.

The line of investigation which (as it appears to me) should be pursued in such inquiry is the following—namely, I should endeavour to ascertain,—first, what is the constitution of organic creation as it *now* exists; or in other words, what is the constitution of the *present generation* of organized beings: and secondly, how or *in what manner* has the present generation been *generated* or formed by the preceding generation. A knowledge of these two facts would (as I conceive) furnish us with data from which to collect a certain amount of information as regards the *necessary* constitution of the *origin* or (if I might venture so to term it) of the *embryo of all generations*. For if the manner in which organized beings universally have been generated, can be *accurately* traced back for *one* generation, there is nothing to prevent its being, with equal accuracy, traced back for *many*, and *the possibility* is that it may, with a certain degree of accuracy, be traced back *for all* generations; that is, in other words, till we have eventually arrived, in imagination, at (if I may so term it) the *embryo* of *all* organic creation.

The two inquiries just referred to (namely, the *present* constitution of organized beings, and *the mode of their formation)*, I have already endeavoured to investigate, and have laid my opinions thereon before my readers; it remains now for us to apply those opinions to the present investigation—namely, to an inquiry into what must have been the constitution of the *Embryo* of all organic creation.

It is scarcely necessary for me to acquaint my readers with the fact, that one great function of every living being is and ever has been to *multiply* the species to which it belongs. One great function for which every existing living being has been created, and which it was consequently designed to fulfil was (and has ever been since the creation of that living being's *first parent)* to generate an *increased number of individuals* of the species to which that living being belongs. The least observant of mankind requires no argument to convince him that every individual living being (in its normal condition) has been endowed with the faculty of generating a *plurality* of individuals of the species to which it belongs. Such fact is too obvious to require further observation. What do we collect from that fact? We collect this—namely, that the tendency of generation is to increase the number of individuals in a species; or in other words, that generation after generation the number of individuals in the various different species of living beings, have *(cæteris paribus)* as a result of generation been constantly becoming augmented, from the time of the *first* existence of such species to the present: that such is the fact, there is no one will question. If, then (as I have endeavoured to convince my readers is the fact), the organic world, *as it now exists*, is composed of individual living beings *which have been formed by the union of a number of minute organisms* or organizing agents (which remember are also *living* beings)—namely, what I have termed organizingatoms. If, I say, organic creation, *as it now exists*, is thus composed, it is obvious that *(cæteris paribus)* generation after generation the number of individual organizing atoms (unlike mineral atoms, the number of which is constant and unvarying), it is, I say, obvious that the number of *individual* organizing atoms comprised under each distinct species of *organizing matter* has been (and still continues to be) *augmenting*, and that such has been the case, generation after generation, from the period of the creation of the *first parent* organizing atom (at which period a *single individual atom*, in all probability, constituted the *entire species* of that atom at the time in existence) to the present period, when the number of atoms comprised in that species is *countless.*

If such be the fact (and perhaps none of my reflecting readers will question or doubt it), let us, in imagination, trace organic nature backward, step by step, from the present time, to the period of its creation. Let us, from the countless myriads of organizing atoms that are *now* in existence, pass successively backwards, from generation to generation,

other words, let us endeavour to ascertain if any analogy can be recognized between the manner in which the various different species of *compound* matter are formed in the inanimate or unorganized world, and that in which the various different species of *living beings* are formed in the living world, or world of organization.*

What, then, let us first inquire, *are* the different kinds of *compound* mineral matter which are to be met with in the inanimate or unorganized world? There are but three orders or classes of mineral matter, to some one of which every chemical *compound*, in the inanimate or unorganized world, must of necessity be referred—namely, such compound must either be—first, a *neutral* compound (that is, possessed neither of what chemists term electro negative, nor of electro-positive properties), such, for example, as water, as also what we term a neutral salt; or secondly, it must be a compound possessed of what by chemists have been named *electro-negative* properties; such, for example, as what in chemistry is called an acid; or finally, it must be a compound possessed of what are termed *electro-positive* properties; as, for instance, those compounds to which chemists give the name of alkali or base. To some one of these three orders or divisions of mineral matter (namely, a neutral, an electro-negative, or an electro-positive compound), every chemical compound to be met with in the mineral world must of necessity be referrible. In a *neutral* chemical compound (and I would beg of my readers to reflect on this fact), we may have these three orders of chemical compound in combination constituting an integral or indivisible symmetrical whole. In a crystal of the salt called sulphate of magnesia, for example, we have an *acid* and an *alkali (by the exercise of those properties or forces peculiar to each as such)* uniting to form what chemists term a *neutral chemical compound*. In every *neutral* chemical compound (and I would desire to impress this strongly on my readers), in every *neutral* chemical compound, I say, in the inanimate or mineral world, we have (as it appears to me) a striking analogue (as regards *constitution* and *mode of formation)* of a *living being* in the living or organizing world.

In the *electro-negative* element of that neutral chemical compound, we may recognize the analogue of the *organism* or *organizing agent* of the living being; in the *electro-positive* element may be seen the analogue of the *residual product* upon which that organism or organizing agent is destined to confer organization. In the neutral chemical compound, we have the electro-negative and the electro-positive elements *(by the exercise of those properties or forces peculiar to each as such)* uniting to constitute a *neutral* compound. In the *living* being we have the organism (or organizing agent) and the residual product (to which that agent is about to impart organization) *by the exercise of the properties or forces peculiar to each as such*, uniting to constitute a *living* being. Thus, then, between such neutral compound and such living being, as regards their constitution and mode of formation, there appears to me to be a striking analogy; but I shall endeavour to point out this analogy more clearly.

We have just seen that in the inorganic or mineral world there are but three orders or classes of mineral matter, to one of which every chemical compound must of necessity be referrible—namely, such compound must be either electro-negative, electro-positive, or neutral. We have further seen that the two former of these three classes of compound in combination may produce a compound of the third class—namely, a *neutral* compound. Strikingly *analogous* facts appear to me to be true of the organic or living world. In it there appear to me to be but three orders or classes of organic matter, to some one of which *every organized structure* must of necessity be referred—namely, such organized structure must either be—first, *an organizing agent*—that is, an organized structure *capable of conferring* organization (to which order of structure I have for perspicuity restricted the term *organism)*; such, for example, what I have named the nervous, the muscular, the glandular, &c., organizing atom, as also the embryo of vegetables, of animals, and of man; in a word, it must be an organized structure, designed and adapted by Nature for *conferring or imparting* organization: or secondly, it must be an organized structure *not capable of conferring or imparting* organization, but designed and adapted by Nature for the performance of some other species of physiological function (to which order of structure I have for perspicuity given the name *organized residual product)*; such, for example, as albumen and fibrin, as also muscular, nervous, glandular, &c. &c., structure: or finally, such organized structure must be *a combination or union of these two*; and such combination or union may constitute what we understand by a *living* being. Of this order or division of organic structures, we have an example in a fœtus, in a vegetable, in an animal, and in man. To some one or other of these three divisions or orders of struc-

---

through the ages that have passed (as the number of those atoms is successively becoming more and more limited), let us, I say, pass backwards till we eventually arrive, in imagination, at the first origin of those atoms; which is, in other words, at the organized world *as that world first existed*. And what do we reach? We reach (as it appears to me) a chain composed of perhaps but a few individual microscopic granules. We arrive, as I conceive, at a *single* representative (in the form of a microscopic granule or organizing atom) of each distinct species of organizing matter: we arrive, as I conceive, at the individual atoms which were the first parents of all subsequent atoms,—the first parents of the countless myriads of atoms now in existence.

These granules constitute what I conceive to have been the *first existing* chain of gradually ascending organisms or organizing atoms. The number of links in that chain may (as I conceive) have been so limited, and their dimensions so minute, as that the entire in combination might (as I conceive), in all probability, have constituted but *a granule of very inconsiderable dimensions*. And what was this granule (or granules)? *It was the embryo of organic creation*. This granule (or granules) was (as I conceive) *one parent* of all since existing organic creation; its *other parent* being (as I conceive) a mineral or unorganized world.

What! some of my readers perhaps may exclaim, *a granule* (or granules) give origin to an organized world!—give being to a widely diffused organic creation! What! *a granule* (or granules) originate the countless varieties both of vegetable and of animal organism which in myriads unnumbered, and during a series of centuries have been spreading life and organization over the entire surface of our globe! Could such be supposed possible?

I repeat it, that to me, as the result of mature and deliberate reflection, there appears to be evidence to induce the opinion, that such is the fact, and startling or strange as such statement may appear, I would beg of my readers not to reject it without reflecting upon what has been advanced. To my mind there appears to be no greater antecedent improbability against such being the fact than there is against the fact, *that the contents of a single Graaffian vesicle could give origin to countless millions of the human race*. I would again beg of my readers *to reflect*.

* Let me be distinctly understood. All inorganic or mineral matter is (as my readers are aware) divisible into *simple* and *compound* matter. Thus, for instance, carbon, oxygen, nitrogen, hydrogen, silver, mercury, &c. &c., are (as my readers are well aware) all examples of *simple* mineral matter; while carbonate of ammonia, nitrate of silver, oxide of mercury, &c. &c. (in which *different species* of mineral matter are chemically combined), are instances of *compound* mineral matter. I have already endeavoured to point out that all organisms (viz., organizing agents) are divisible into simple and compound organisms, and have further endeavoured to show that an organism (or organizing agent) *in conjunction with what I have termed a residual product* (that is, in conjunction with something upon which that organism can *confer* organization), is essential to constitute a *living* organism; that is, in other words, is essential to consitute what we understand by a *living being*. My present object is to endeavour to point out that the manner in which the various different species of *compound* mineral matter are formed, in the inanimate or unorganized world, is *strikingly analogous* to that in which the various different species of organic compounds; viz., simple living beings, compound organisms, compound residual products, and finally, *complex living beings*, are formed in the living or organizing world.

ture every form of organized matter in existence must (as it appears to me) of necessity be referred. Let us now contrast the manner in which the three different orders or classes of compound are formed in the two great divisions of Nature, and observe how striking appears to be the analogy between the mode of their formation in each.

In the inanimate or unorganized world two *simple* atoms—namely, for example, one of oxygen and one of hydrogen (possessed respectively of what are termed electro-negative and electro-positive properties) unite, in obedience to the properties or forces peculiar to each, and form in union *the simplest species of neutral chemical compound.* In the living or organized world the simplest species of organizing agent (namely, the humblest conceivable of vegetations) and the humblest conceivable (if I might so term it) residual product (namely, inorganic or mineral matter), possessed respectively of an adaptation for *imparting* and for *receiving* organization (that is, the organizing agent having been designed and constructed by Nature for *conferring* organization, while the so-called residual product (namely, unorganized or mineral matter) was adapted by Nature for becoming organized, or in other words, has been designed and constituted for *receiving* organization), in, I say, the living or organizing world, the simplest conceivable organizing agent and the simplest conceivable residual product, in obedience to the properties or forces which are peculiar to each, unite, and form in union the simplest conceivable *living* being. I say *living* being, inasmuch as until such union has taken place between that atom and mineral matter, the former could not be said to be *living* or *manifesting* life. Thus, then, there appears to me to be a close analogy between the manner in which the *simplest* species of *neutral* chemical compound is formed in the inanimate world and that in which the *simplest* species of *living* being is caused to *manifest* life in the world of organization. Let us see if this analogy can further be traced between the manner in which the more complex *neutral* compounds (such as crystallized salts) are formed in the inanimate or mineral world, and that in which the more complex *living* beings (such as a fœtus or man) are caused to *manifest life* in the animate world, or world of organization. In the inanimate or unorganized world, we find *simple* atoms of different species of inorganic or mineral matter uniting to form a *compound* atom, possessed of what are termed electro-negative properties, to which compound we give the name of acid. Thus, for instance, in accordance with the laws of chemical affinity, carbon and oxygen unite, and form the electro negative compound, which we call carbonic acid. In accordance with the laws of the same chemical affinity, *simple* atoms of other species of mineral matter unite and form a *compound* atom, possessed of what are termed electro-positive properties, to which compound we give the name of alkali or base. Thus, for example, in obedience to the laws of chemical affinity, nitrogen and hydrogen unite and form that compound which chemists call ammonia. And, finally, these two *compound* atoms, possessed respectively of electro-negative and electro-positive properties, in obedience to the properties or forces peculiar to each, unite, and in union constitute a *symmetrical crystallized salt.* So, too, in the animate or organized world, or in *living* or *organizing* creation. In it, too, we find *simple* organizing atoms, in obedience to the laws of organic affinity, uniting to form a *compound* organizing atom *adapted for imparting or conferring organization.* Thus, for example, the *simple* nervous, muscular, vascular, glandular, &c., organizing atoms unite to form the *compound* organizing atom—*the embryo of man.* By the laws of the same organic affinity, we find *simple* organized residual products uniting to form a *compound* organized residual product *adapted for receiving organization;* such, for example, as that organized residual product which I have named the specific stimulus of the embryo of man. And, finally, we find these two *compound* atoms (possessed respectively of an adaptation for *imparting* and for *receiving* organization), in obedience to the organic properties or forces peculiar to each, uniting to form the *living* embryo of man.*

To dwell further upon this analogy in connexion with the subject under present consideration, would perhaps be regarded by my readers as undesirable. Thus much, however, I conceived might be advantageously submitted to their judgment as a concise and perhaps not altogether unimpressive illustration of the nature of the relation which I conceive to subsist between what I regard as *the two great essentials* to constituting what we understand by a *living being*—namely, something *to organize* or *to impart* organization, in conjunction with something *to be organized* or which is *to receive* organization. In other words, the nature of the relation which I conceive to subsist between what I have termed *an organism* (or organizing agent) and *a residual product.*

There is one additional point in connexion with this analogy (that is, in connexion with the analogy which to me it appears may be recognized between *the constitution,* as also the *manner of forming,* of the objects respectively of inanimate and of living creation), there is, I say, one additional point in connexion with this analogy, upon which (although in my mind *most striking,* and, as I regard it, of the utmost physiological importance) I have not considered it desirable at present to dwell. I allude to the very striking analogy which (as it appears to me) may be recognized between the manner in which an imponderable principle named caloric (or which, to avoid hypothesis, may be termed the *heating agency),* has been caused *to associate itself with* (or become *latent* in) ponderable matter, and again *to extricate itself from* (or become *manifest* in) such ponderable matter *in order to produce the required inanimate phenomena;* and the manner in which (what to me appears to be in several respects) an analogous imponderable principle named the vital force (or which, to avoid hypothesis, may be termed the *organizing agency),* has been caused to *associate itself with* (or become *latent* in) ponderable matter, and again *to extricate itself from* (or become *manifest* in) such ponderable matter, *in order to produce the required living or organic phenomena;* I have not, I say, considered it desirable at present to dwell on this subject, and that inasmuch as it would not admit of being adequately investigated without an attempt upon my part to point out what to me appears to be erroneous in the opinions of others as to what it is which *constitutes organization.* Such effort upon my part could not be indulged in without drawing my readers' attention too widely apart from the topic more immediately before us, and I shall consequently look forward to the privilege of

* The same is equally true with regard to the organism *man*—namely, the result of the function of that embryo. In the compound organism man, the liquor sanguinis of his blood is the *compound residual product* upon which, and upon which only, the component atoms in that organism can by possibility discharge their specific physiological function *of organizing.* That is the only residual product upon which the compound organism man *can confer an increased organization;* or, in other words, the only residual product which the component atoms in that organism (namely, the nervous, the muscular, the vascular, the glandular, &c., atoms), the sole residual product, I say, which these atoms can raise *still higher* in the scale of organization, converting its fibre, &c. (as we know to be the case), into a *more highly organized matter*—namely, into what we term nervous, muscular, vascular, glandular, &c., structure. Deprive the organism man of the liquor sanguinis of its blood, and what is the result? The result is this—namely, that that organism ceases to be a *living* organism. And wherefore such result? The organizing atoms of which that organism is composed are still in existence, and wherefore are they not still *living* organisms? Why is it that those organisms do not *still manifest life?* Simply because having been deprived of their *residual product* there is nothing upon which they can discharge their physiological function of *organizing;* nothing which could enable them to manifest the phenomena of *living.* For an organism (or organizing agent) *in conjunction* with a residual product is (as I have endeavoured to point out to my readers) essential to constitute a *living being.*

again meeting my readers upon some future occasion in an attempt at a full investigation of this (as I regard it) important consideration.

Having now brought my preliminary observations to a close, I shall, in my next communication, proceed to the consideration of *the formation and appropriation of fibre.**

(To be continued.)

* By the term *organism*, wherever employed in these papers, my readers will bear in mind (as I have already informed them) that I mean simply to express *organizing agent*, and that these two expressions (namely, *organism* and *organizing agent*) wherever employed *in these observations*, are used as convertible terms. This being understood, the following is a concise summary of what I have endeavoured to convey to my readers in relation to what I conceive to have been *the original constitution* of organic creation, as also the manner in which, I conceive, organic creation, *as it now exists*, has been generated *(out of an inanimate or unorganized world)* by organic creation as originally constructed. These opinions I have considered it desirable to exclude from the text, apprehensive that they might be objected to as *hypothetic;* the reader, however, will observe that they in no way affect the deductions I have endeavoured to establish in the text as regards the *present* constitution of organic creation.

1. A chain of microscopically minute organisms (or organizing agents) gradually ascending in the scale of organization, appears to me to have been originally created. The entire of these organisms collectively (from the extreme minuteness of each granule, and from their number being probably limited), the entire of these organisms, I say, collectively, *might possibly*, as I conceive, if united, have been comprised within the compass of *a granule of very inconsiderable dimensions.*

2. To this granule (or granules), being, as I conceive, the origin, or source of the generation, of all subsequent organization, I would give the name *embryo of organic creation;* and the function of this embryo was (as it appears to me) *to organize* what hitherto had been unorganized matter; in a word, to generate an animate or organized world *out of inanimate or unorganized creation.*

3. To *each link* in the original chain of gradually ascending organisms (being possessed, as I conceive, of a *degree* of organization peculiar to itself; that is, each distinct link having, as I conceive, a distinct *degree* of organization) to each of those links (originally probably comprised in a *single individual* microscopic organism), to each, I say, of those links in the first formed or original chain, I have given the name of *distinct species of organizing matter;* so that *all the links* (comprised in the first existing chain of organizing agents) would collectively, as I conceive, constitute all (what I have termed) the different *species of organizing matter* now in existence.

4. The number of such *different species of organizing matter* existing in Nature, appears to me to be far from considerable. The *individual* organisms *(now* countless myriads, though at *the commencement* of organic creation, in all probability, as it appears to me, but a *single individual),* the individual organisms, I say, comprised under each distinct species of organizing matter, being, as I conceive, physiologically atomic or indivisible, I have ventured to name *organizing atoms.*

5. Every organism, having been endowed with a faculty of generating a *plurality* of its species, the number of individual organizing atoms comprised under each distinct species of organizing matter, has (during successive generations) been increased from, probably, one single individual, as I conceive, to the countless myriads which now exist throughout Nature.

6. The function of every organism being, as I conceive, *to organize* (that is, to *impart* organization, or in other words to *confer certain definite arrangement),* the function, I say, of every organism being to organize, the chain of organisms or organizing agents originally created—namely, what I have termed the embryo of organic creation, must have had *something* upon which to execute this function—must have something which it could organize or definitely arrange.

7. That something was (as it appears to me) for the *first* chain of organisms, *the unorganized or mineral world;* and the following appears to me to be the manner in which that function was performed, so as eventually to generate the organized world as that world now exists. In other words, the following appears to me to be the manner in which the *first existing* chain of microscopic organisms (all of which collectively would, as I conceive, in all probability, have constituted but an inconsiderably sized granule), the manner, I say, in which the *first* existing chain of granules so acted upon the unorganized or mineral world as in the course of succeeding generations to have given development to everything called *organic* that has since been in existence,—namely,

In the first place, I conceive that *the first link* in that chain (or *simplest species* of organizing matter) discharging its function (of organizing) upon *an unorganized* or mineral world; *organized* mineral matter forming or generating therefrom *two distinct classes* of organized product—namely, first, a *plurality of organizing atoms*, in all respects identical with itself, and, like it, capable at some future period of *imparting* organization to *unorganized or mineral matter;* and secondly, an organized product *not capable of imparting* organization (and consequently not an organizing agent), but capable of receiving (increased) organization from the *second* link in the organizing chain. To this second class of organized product, I have, for perspicuity, given the name *residual product,* inasmuch as it remains, as it were, *a residue,* till the function of the second link or species of organizing atom, comes into operation.

In the second place, I conceive that the *second link* in that chain discharging its function of organizing (not upon unorganized or mineral matter but) upon *the organized residual product* prepared or generated for it (out of mineral matter) by the first; conferred upon that organized product *increased* organization, thereby *raising it in the scale of organization*, and then forming or generating therefrom *two distinct classes* of organized product—namely, first, a *plurality of organizing atoms* of the second species, in all respects identical with itself, and, like it, capable, at some future period, of imparting increased organization to organized residual products, to be generated at some future period by the plurality of atoms of the first species which we have just seen reproduced; and secondly, an organized product *not capable of imparting* organization (and consequently not an organizing agent), but capable of receiving (increased) organization from the *third* link in the organizing chain; to which product I have, for the same reason as in the case of the first link, given the name *residual* product; and so of the several succeeding links in the organizing chain. Each individual link generates, as I conceive, *a plurality of organizing atoms* of the same species as itself; and at the same time generates *an organized residual product.* Each individual atom having, then, been thus endowed with the power of generating *a plurality* of atoms of its own species, as also a *residual product*, it is obvious that the number of individual organizing atoms, as also the number of organized residual products (which are capable of calling those atoms into action, or upon which those atoms can discharge their physiological function of *conferring organization*), it is, I say, obvious that the number of individual atoms and of residual products existing in Nature, is, generation after generation, *constantly augmenting.*

The following is the manner in which I conceive that the various *atoms* and the various *residual products* thus formed, were disposed of. I conceive, in the first place, that various *organizing atoms*, thus generated, entering into combinations of various species, various numbers, &c. (in obedience to the laws of organization), constituted, in combination, *the first or earliest embryos* of various different species of vegetable and animal; and I conceive, in the second place, that *organized residual products*, thus generated, entering into combination in corresponding variety as to species, &c., constituted, when thus combined, the various compound residual products required by Nature to enable those embryos to discharge their physiological function. And finally, I conceive that these embryos and their residual products (namely, the specific stimuli of the embryos) brought into combination by the laws of organization, developed in union the *first existing* individuals of several different species of vegetable and animal.

Such is my opinion as to how *the first generation* of living beings has been formed. *How*, as I conceive, subsequent generations have been generated by the first, I have already endeavoured to lay before the reader.

HÆMORRHAGE AFTER GUNSHOT WOUNDS.

M. Sistatch stated to the Surgical Society of Paris that, from observations upon numerous cases, he had come to the conclusion that the hæmorrhage after gunshot wounds is more frequently primary than secondary. This was contrary to the generally received opinion, but it was based upon 350 instances seen by him at Djidjeli in 1851, out of which number only two examples of secondary hæmorrhage occurred.

EFFECT OF ACCIDENTAL INJURY OF THE PENIS.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—Should you think the enclosed worth publishing in the PRESS, I will feel much obliged by your doing so.—I am, dear sir, yours truly, THOMAS D. MAYBURY.

Killarney, October 26, 1851.

Patrick H—— of Killarney, aged 32, following the occupation of master baker, sent for me on the 25th of September. I found him labouring from a very sudden erection of the penis, which he could not get down. He gave me the following history of the case: While playing ball, one of his comrades, on making a stroke at the ball, accidentally hit him on the penis, which was at once thrown into a state of erection, accompanied by a sense of constriction about its centre. His pulse was 120; countenance pale and haggard; no appetite; passed water with difficulty. I ordered him warm stuping and small doses of tartar emetic solution. On the third day not having got any relief, I ordered him leeches and cold applications. On the sixth day, the erection state continuing, and not having got any rest for several nights, I ordered him a quarter of a grain of acetate of morphia in a draught and a liniment of camphor mercurial ointment, extract of belladonna and lard, a small portion to be rubbed into the dorsum penis every morning, and the whole of the penis to be wrapped in the ointment spread on fine linen. This had a most wonderful effect: the penis began gradually to subside, and in three days after all erection had ceased.

ACUTE RHEUMATISM CURED BY LEMON-JUICE.

(Under the care of Dr. BABINGTON.)

IN the second volume of this journal, we directed the attention of our readers to a new and successful method of treating acute rheumatism, introduced by Dr. Owen Rees. The favourable results had been obtained by the administration of lemon-juice, and we then stated, "it appears that Dr. Rees's colleagues, Drs. Addison and Babington, who coincide with him in his views as to the efficacy of the remedy, have put the lemon-juice to the test, and found it extremely useful." Further trials have had the effect of establishing more and more the great value of lemon-juice as a therapeutical agent in acute rheumatism; and so convinced has Dr. Babington become of the value of this simple medicine, that we find him state, in the introductory lecture for this session, that Dr. Rees's new method of treating acute rheumatism held a prominent rank among the strides which have been made in the various departments of medical knowledge since his (Dr. Babington's) pupilage.

It is certainly with good reason that Dr. Babington passed this encomium, for he has prescribed the lemon-juice in numerous cases, and has found it answering the most sanguine expectations. Of a few of these cases we shall subjoin abstracts, in order to put our readers in possession of the facts upon which rests the reputation of the new remedy. We would, however, first mention some remarks of great importance which were made by Dr. Babington.

The lemon-juice which was employed was procured from a wholesale confectioner, the price being no more than sixpence per pint, when retailed in small quantity, and considerably less when furnished by the gallon. When Dr. Babington commenced making trials of the lemon-juice, he prescribed it, according to the recommendation of Dr. Owen Rees, in doses of from one to two ounces, three times a day, for an adult. More recently, however, he had ordered not less than three ounces, and much more—usually six ounces—taken at a draught, and without any admixture, three times a day. It might be supposed that the patient would find some difficulty in drinking so large a quantity of such a sour liquid, but this is rarely the case; nor does it in general produce tormina, nor otherwise disagree with the alimentary canal. Instead of relaxing the bowels, as might have been expected, it renders them somewhat costive, so that it not unfrequently becomes necessary to exhibit an aperient. The juice produces no very decided effect upon the kidneys, merely tending by its quantity to promote their secretion. In increases cutaneous action, but to what extent it is difficult to determine, because in rheumatism, a disease in which this remedy is chiefly useful, the complaint itself is marked by the occurrence of profuse perspiration. The only unequivocal effect which uniformly takes place is a diminution in the number and power of the pulse, and of the heart's action. Whether it alters the character of the blood, or whether it affects the heart by diminishing nervous influence, Dr. Babington has not had an opportunity of determining.

We shall now shortly allude to eight cases, which were treated with lemon-juice by Dr. Babington.

Case 1.—James D——, a tall and athletic young man, a dock labourer, aged 22, was admitted into Naaman's ward, August 20, 1851, with acute rheumatism. He has a white and coated tongue, profuse perspiration, thirst, a hard, full pulse at 92, and costive bowels. There are swellings in the knees and wrists, which are red and tender to the touch, and his debility is so great that he is scarcely able to walk to his bed.

The patient stated, on admission, that he had been ill three weeks, and that he had suffered from a similar attack eight years before, which lasted for one month. There were no irregular sounds about the heart.

Treatment.—To take six ounces of lemon juice three times a day; a drachm of compound rhubarb powder to be given on the morning following admission. First day. Bowels relieved; pulse 76, softer; patient has less pain in the joints; to continue the remedy. Third day. Pulse 70, soft; no pain or swelling of the joints. Patient is up and dressed; he declares himself quite well, and requests to be discharged. He is asked to remain a day or two longer to improve his general strength; but he declines, as he states that he is well able to work.

Case 2.—Samuel H——, aged 19, of slight form, a warehouseman, much exposed in his work to currents of air; never before had any similar attack. For four or five days he has had slight swelling and tenderness in the knees and ankles.

On admission into Naaman's ward, on September 10, 1851, there were great swelling, redness, and intense pain of the right elbow-joint, extending both upwards for several inches and downwards into the wrist. The tumefaction was so severe, that it was a question whether the inflammation was not rather phlegmonous than rheumatic, but the pain and swelling in the other joints settled this point. Tongue moist but white; pulse 116, full; bowels regular; skin perspirable. To take six ounces of lemon-juice three times a day; low diet. First day. Pulse 100, softer; bowels regular; arm and elbow joint much the same as yesterday. To go on with the remedy. Fifth day. Pulse 88, soft; the pain and swelling of the elbow have decreased rapidly since the last visit, and are now very slight; bowels still regular. Eighth day. No pain anywhere, but still some stiffness of the right elbow-joint, which prevents the complete extension of the arm. Bowels regular. Twelfth day. Dismissed, free from all complaint, and having the full use of his right arm, the elbow-joint of which has returned to its natural size. This patient required one dose of the compound rhubarb powder during the treatment.

Case 3.—James S——, aged 20, a baker, much exposed to heat and cold in working at night; never before had a similar attack; has suffered for ten days pain and swelling of both shoulder-joints. Admitted into Naaman's ward on September 10, 1851, having great pain and swelling of both shoulders, but especially the left, so that he is very reluctant to attempt to raise the left arm. Pulse 108, hard; skin hot; tongue white and dry; much febrile excitement; bowels confined. Ordered six ounces of lemon-juice three times a day; fifteen grains of compound extract of colocynth to be taken at night. First day after admission. Bowels well relieved; pulse 82; less pain; to continue the lemon juice. Fifth day. Pulse 80; pain and

swelling much abated; to go on. Eighth day. No pain or swelling; is able to raise both hands above his head, and so far as regards the rheumatism, is well. Patient continues in the hospital in consequence of a swelling in the groin, which was opened two days after his admission, and is going on favourably. He required purgative medicine every alternate day whilst taking the lemon juice.

Case 4.—John H——, aged 22, a policeman, formerly a farm-labourer, with florid complexion, light hair, and strumous appearance; habits temperate. The patient was attacked with acute rheumatism three years ago, but has since had good health, until within the last fortnight, when he began to suffer from his present illness. The inner sides of each foot and ankle were first affected, and then the elbows and hands became swollen, red, and painful, in which state he was admitted into Naaman's ward, No. 8, on July 9, 1851. There was then a murmur heard on the heart's systole; pulse 104, hard, strong, and incompressible; tongue coated and white; countenance congested; appetite gone; bowels costive; urine acid, specific gravity 1010, about one quart passed daily; perspiration profuse; pulse 92. Ordered six ounces of lemon-juice, three times a day. First day after admission. The pain and swelling of the elbows and hands decreasing: ordered to continue the remedy. Fifth day. The lemon-juice seemed to cause a little griping pain in the bowels, which were moved twice a day whilst its use was continued. The pulse 80; small, weak, and compressible. There remained not a vestige of pain nor swelling anywhere. Tenth day. Pulse still 80; no *bruit* heard now with the systole of the heart. The patient has been quite free from all complaint for several days. The pulse retains the same character as on the fifth day. Discharged cured.

Case 5.—William B——, aged 35, a married man, employed as a waiter, a native of Dorsetshire, who has lived in London for sixteen years; temperate, intelligent, with clear complexion, dark hair, and having excellent ordinary health. Five years ago, in the winter, he was laid up seven weeks with rheumatic fever. This had been his only illness since childhood. Admitted into Job ward, No. 18, on July 9, 1851. The knees, ankles, and the small joints of the left hand swollen, somewhat red, heated, and very painful on the slightest motion; chest healthy; heart normal; appetite good; skin hot and dry; urine loaded with lithates, scanty, about a pint daily; bowels regular. Ordered four ounces of lemon juice three times a day. First day after admission. To go on; the juice produced no uneasiness of the bowels or diarrhœa. Eighth day. The pain and swelling having almost entirely ceased, the patient was ordered sesquicarbonate of ammonia, five grains; decoction of cinchona, one ounce; three times a day; that he might recruit his strength. Ninth day. Much better; the joints are entirely free, except the knuckle of the middle finger of the left hand, which is swollen; and this the patient attributes to pressure of the walking-stick which he uses to assist him in moving about the ward. His knees fail him from mere weakness; but they are free from pain. He is considered nearly well of the rheumatism, but remains under treatment on account of inflammation of the right eye.

Case 6.—Thomas M——, aged 26, single; a cooper, living in Commercial-road, Old Peckham; admitted into Naaman's ward, No. 14, August 20, 1851. Aspect phlegmatic; has been a hard drinker, but has otherwise lived well. His general health has always been good. Had syphilis about six years ago, but it was not followed by any secondary symptoms. About five months ago, the patient was attacked with loss of power in the motor nerves of the right arm,—probably rheumatism,—for which he was admitted into St. Thomas's Hospital, and discharged cured three months afterwards. About six weeks ago, he was attacked with general rheumatism, and from that time has been unable to work. He has not, however, been under medical care, and has not taken any medicine.

Present Symptoms.—Complains of severe pain in the back of the neck and between the scapulæ, which is constant, but increased on the slightest movement. Pulse 96; tongue slightly furred; skin hot and dry; bowels regular; has slight pain in the head; sleeps well, and is not disturbed by the pain during the night. Six ounces of lemon-juice three times a day. First day after admission. Is much relieved. Pulse 76; skin moist. To go on. The fifth day. The pain is much less severe, and is intermittent. Pulse 72, soft; skin moist and cool; bowels regular; to go on. Eighth day. Complains of want of sleep; the pain is now only felt on walking, or moving the affected parts. Ten grains of Dover's powder every night, and repeat the lemon juice three times a day. Eleventh day. Complains of pain in the head, probably caused by the opiate at night, which, as he now sleeps well, he is directed to omit, still continuing the lemon-juice. Fourteenth day. Patient can now move his head in any direction without the least pain. The uneasiness between the scapulæ, however, still continues when he moves his arm or walks. Ordered to omit the lemon juice; to be dry rubbed between the shoulders on alternate days, and to take a draught of magnesia, with wine of colchicum in mint-water, three times a day. Sixteenth day. Is now free from pain; and having remained so until the nineteenth day, he was discharged cured.

Case 7.—Samuel T——, aged 66, married, living at 9, Pollen-street, Maddox street, one of the pew-openers of St. George's, Hanover-square, a stout man, with fair, florid complexion and grey hair. Has been the subject of gout for twelve years, within which period he has had four very severe attacks, at intervals of about two years and a half, which have stiffened his joints so that he can hardly hobble along.

On Tuesday, 15th July, 1851, having had for three days well-marked gout, with much pain in his left hand, he was recommended to try lemon-juice; and on the evening of that day, he took two ounces. On the second day he took six doses, each of two ounces, at intervals of about three hours. On the third day he took five doses. On the fourth day four doses. On the fifth day four doses.

On Sunday, the sixth day, in consequence of having to attend his duties in the church, he omitted the lemon-juice altogether. On Monday, the seventh day, he took a wineglassful three times in the course of the day. On the eighth day, two wineglassfuls. On the ninth day he took none. On the tenth day he took one wineglassful, and then left the remedy off altogether.

His account of the effect is as follows:—On the fifth day he began to get ease. On the following day his duties fatigued him much, but he had no pain. On the seventh day he felt a kind of shaking or throbbing in the hand, which lasted for several hours; the hand then gradually became pliable, having been stiff before, and from that time he has felt quite well, the few doses which the patient took on the eighth and on the tenth day being merely taken by way of precaution, for fear of a relapse. His limbs, which had been long stiffened with gout, the last attack of which confined him to his bed for many weeks, have become more and more pliant, and he states that he has not felt so well for the last twelve years, having a good appetite, sleeping well, and being able to move about without pain, and with tolerable freedom. He says that the lemon-juice did not open his bowels, but that when he took twelve ounces in the day he had some griping pains. The patient has had no attack of gout up to the present time, Nov. 1.

Case 8.—Ellen L——, aged 20, a florid young woman: whilst in service she met with an accident from the fall of a box, which struck her side. Two or three weeks afterwards she began to expectorate blood, and this continued for two months. She was then admitted into Lydia ward, on the 18th of June, 1851, and continued under treatment until September 9th—viz., about three months. During this period she continued to cough up blood almost without intermission, to the extent of from a quarter to half a pint daily. The catamenia, though regular, were scanty, and her complaint was regarded as dependent on imperfect menstruation.

Various remedies, as well astringents and sedatives as

saline aperients, were tried, with but partial success; and although the repeated application of leeches to the side was more efficacious, still the bleeding recurred until the 18th of August, when she began to take three-ounce doses of lemon-juice, three times a day. From that time to the present (October 14), she has had no return of the complaint. With this patient, as with all who have followed this treatment, the lemon-juice had the effect of lowering the power and frequency of the pulse.

Dr. Babington stated, in some remarks he made on the subject, that from the above cases, and many others not recorded here, he had come to the same conclusion as the original discoverer, Dr. Rees,—namely, that in *acute rheumatism*, or as it is otherwise called, rheumatic fever, whatever be its severity, there is no remedy with which he was acquainted, possessing anything approaching the curative power of lemon-juice. Dr. Babington had never seen nor even read of such speedy cures by any means whatever, as were effected in the six cases which have just been narrated. Of these cases it will be observed that the first got well in three days, the second in eight days, the third in eight days, the fourth in five days, the fifth in nine days, and the sixth in sixteen days. The seventh case, though not of the same complaint, is equally remarkable. Inveterate gout occurring in a man, aged 66, was materially improved, and a renewed attack was subdued by a few days' employment of this perfectly safe remedy; and in the eighth case an obstinate hæmorrhage from the lungs was arrested and permanently cured by the same means.

Dr. Babington further remarked, that since Dr. Rees first recommended lemon-juice, it has been employed by many medical men, and, as he understood, with variable success. He was inclined to attribute occasional failures, of which he had himself met with several, to the fact that according to his experience it is, as before stated, in acute rheumatism alone that the remedy proves so certain; whereas it has been administered in all kinds of cases.

Dr. Babington did not mean to affirm that it is not also very frequently useful in chronic rheumatism, and in gout, but only that its effects are far less obvious, and far less uniform, in these diseases. Failure, or at least a want of striking success, may also be ascribed to the circumstance that the doses administered have hitherto been too small.

It was only within the last four months, that he had ventured to prescribe more than from one to two ounces for a dose; and Dr. Babington believes that scarcely any one but himself has hitherto exceeded the latter quantity. He claimed no merit for having adopted a bolder practice, for the change resulted from the following circumstance.

A gentleman, who had consulted Dr. Babington several months before, called about severe rheumatic pains which he was experiencing. He was recommended to take lemon-juice. From some cause or other, however, the patient did not take it; and after an interval of several months, being again visited by his rheumatic pains, he applied to a chemist for relief. This person told him he ought to try lemon-juice, and it then flashed across his mind that this was the remedy which Dr. Babington had long before spoken of. The gentleman told the chemist he would follow his advice; but "what is the dose?" said he. The chemist replied, "*half a pint* (!) three times a day," and added that this was the quantity which he himself had taken for a similar attack, and with the greatest success. The patient, a gentleman of a resolute spirit, unflinchingly took the quantity prescribed, which, however, he found it somewhat difficult to swallow, and, according to his own account, in three days he was well.

Dr. Babington asked him what effect it had upon his bowels, and learned that the patient had been astonished to find that it did not disagree with him in any way, although his bowels were remarkably tender and easily put out of order. It being thus clearly proved that even eight or ten ounces of lemon-juice taken at a dose were not productive of any ill effects, Dr. Babington from that time felt warranted in increasing the quantity; and the remarkable effects he had witnessed, of which the cases above cited are but a few samples, were the fortunate results.

From the depression of the circulation caused by lemon-juice taken in large doses, Dr. Babington considers it highly probable that it will be found a valuable remedy in inflammatory diseases in general. He intends to take an early opportunity of trying it in pneumonia or pleurisy, as he thinks that it will act as beneficially in those diseases as antimonials, and much in the same way, with the exception of the nauseating effects—namely, by lowering the circulation and promoting perspiration.—*Lancet.*

ON A RARELY OBSERVED BUT VERY FATAL EFFECT OF GASTRO-INTESTINAL REVELLENTS:

ESPECIALLY OF THE TARTRATE OF ANTIMONY AND POTASSA, AND PARTICULARLY IN THE TREATMENT OF PNEUMONIA.

By Dr. Boling of Montgomery, Alabama, U.S.

There are but few articles of the materia medica which exercise so certain a control over any serious morbid state or action, as the tartrate of antimony and potassa does over inflammation of the pulmonary parenchyma. Its efficiency, I may say, is universally admitted. Unfortunately, however, its value as a remedy in pneumonia, or any other disease indeed in which its protracted use may be required, is diminished by the circumstance of its occasioning in many instances, violent disease of some of the abdominal viscera, which often leads to a fatal result. It is in pneumonia, however, according to my own observation, that the effect referred to is most frequently produced by it, and developed in the most violent and rapid manner; probably, it is but reasonable to suppose, because in this disease its protracted administration is more frequently practised than in any other. As generally administered, it is not improbable, that the remedy, even in cases in which the ultimate result may be favourable, produces by its contact, more or less irritation of the gastro-intestinal mucous membrane, which gradually subsides, after its suspension, during convalescence. Its visible effect upon the skin, when used locally, might lead to such an inference, and indeed appearances somewhat analogous to this are sometimes observable, not only after death, in the gastro-intestinal mucous membrane, but during life, in the mouth and fauces, as a result seemingly of its use. It fact, it is to a revellent effect, resulting from this local irritant action, that its efficacy in pneumonia and other diseases is attributed by the advocates of the physiological doctrine. It is not, however, this local action, *merely as spoken of and described by the generality of writers*, to which it is my object to call attention at present, but more particularly to an array of symptoms of a much more violent and sudden character, connected seemingly with a metastasis of morbid action, from the thoracic (when administered in the diseases of this cavity) to the abdominal viscera; the result, it may be, of an exaggerated influence of the character mentioned. Whatever the correct explanation, however, as to the mode in which the effect is produced, the condition itself is one of extreme danger.

There is reason to believe, however, that though in the treatment of pneumonia, the state in question is more frequently induced by the use of tartar emetic than by anything else, a similar condition is occasionally brought about by other agents administered to such an extent as to produce a high degree of irritation of the gastro-intestional mucous membrane; and I believe that it is with more certainty developed, under a combination in the treatment, of calomel with the antimonial, than by the latter alone.

Supposing the remedy to have been continued several days, the phenomena referred to are developed much in the following manner. The patient may seemingly be doing well under the continued use of the remedy; the dulness on percussion and the frequency of the pulse diminishing; the skin perhaps becoming moist, and the respiration improving. Suddenly in some cases, in others

somewhat gradually, the patient becomes restless, the thirst is augmented, the discharges from the bowels are more numerous and thin, the abdomen becomes tympanitic and perhaps tender, the tolerance is lost, and though he may not have done so for several days, he vomits, or makes frequent efforts to do so; the tongue becomes dry and pointed; there is jactitation present, anxiety of countenance, delirium, and perhaps stupor a short time before death. Occasionally jaundice supervenes, and in a few cases the matter vomited bears a close resemblance to that ejected in yellow fever. During the progress of the change, the pulse becomes more frequent, hard, concentrated, small and thready.

The rapidity with which the symptoms mentioned are developed varies a good deal in different cases. I have known instances in which death has taken place in about six hours from the time of the first evident unfavourable change; in every respect, up to that time, the progress of the case being apparently favourable, and the graver symptoms subdued. Oftener the case is protracted to ten or twelve hours, and sometimes to a longer period.

Simultaneously with the changes above spoken of, or, as it were, preceding them rather, a more or less rapid disappearance of the signs and symptoms of the primary disease takes place. From a state of almost complete solidification of an entire lung, with dulness on percussion, and bronchial respiration, in the course of four or five hours, I have found the pulmonary tissue permeable, and the chest resonant and yielding a healthy respiratory murmur; a corresponding improvement in the cough, thoracic pain, difficulty of breathing, &c., proceeding at an equal rate. The rapidity with which this change in the condition of the lung takes place is proportionate to the violence and rapidity of the newly developed abdominal disease.

In any case of pneumonia under the antimonial treatment, although the patient may seemingly have been doing well, the supervention of the slightest tympanitis, with augmented thirst and a tendency to diarrhœa, may be regarded with suspicion, as the probable precursors of a very grave condition; and I am now led to regard my patient's doom as almost settled, when, in addition to these symptoms, there is a *rapid* instead of a gradual removal of the dulness on percussion, *unattended with the crepitant râle of resolution.* Where a case is closely watched, the latter will be found to precede somewhat the former symptoms of the progressing change; and I have more than once surprised, not only the relatives of patients, but professional gentlemen in attendance with me, by announcing a coming change for the worse, basing my opinion on the physical sign just stated, where everything otherwise seemed favourable, the patient comfortable, and apparently perhaps convalescent.

This termination of pneumonia, under the administration of antimonials, especially when given in what would be considered anything like adequate doses by the advocates of the doctrines of Rasori, I am led to believe cannot be of very rare occurrence in the South; for I think that I have seen almost as many patients die of the superinduced or substituted affection as of the primary. And yet the largest quantity for the twenty-four hours, in which I have been in the habit of prescribing the tartrate of antimony and potassa, falls far short of what would be considered a medium dose for the same time by the generality of physicians of the contra-stimulant school. Under the supposition, however, that it not unfrequently occurs, it is somewhat strange that we find so little in the works of authors who have written on pneumonia, especially as treated with antimony according to the contra-stimulant doctrine, in which anything like a distinct reference is made to it, much less an accurate account of the condition. Neither in the French nor Italian writers of the contra-stimulant school accessible to me have I been able to find any account of it, though in many we find allusion to the mere local irritant action of the agent in question upon the gastro-intestinal mucous membrane. This is more especially, however, the case among the advocates of the physiological doctrine, by whom the curative influence of the remedy in question, in pneumonia, is ascribed to a revellent operation. The condition spoken of by the followers of Rasori as a loss of the tolerance, resembles it in many respects, and I have sometimes suspected that in their descriptions they may have had in view a state identical with that to which I now have reference. If so, however, their delineation is incomplete in several important particulars; and I would especially mention the sudden subsidence of the original disease, with the occurrence of the new train of alarming symptoms. Moreover, no one, I imagine, who has ever observed a well-marked case of the state to which I have reference, even under the influence of a favourite doctrine, could see in it *merely* a general depression of the vital powers somewhat below the standard of health; and, in short, could suppose that the phenomena manifested were not the consequences of actual local lesion of the viscera of the abdomen.

I have been disappointed in not finding an account of it in such of the writings as I have met with of the Italian followers of Rasori; because, not only from the immense doses in which they are in the habit of administering the antimonial preparations, but from the similarity of their climate, and diseases generally, to our own, in their hands especially, I had been led to suppose it must frequently occur. Owing to the fact, that in the North the susceptibility of the gastro-intestinal mucous membrane to irritant impressions is less than in the South, it probably occurs less frequently there than with us. One rather mild, but unquestionable case, I find recorded in the *American Journal of Medical Sciences* for April, 1848, by J. F. Peebles, M.D., of Petersburgh, Virginia, in a paper calling attention to certain unfavourable effects of tartar emetic. Two other cases are given by B. R. Jones, M.D., of Montgomery, Alabama, in the *New Orleans Medical and Surgical Journal* for September, 1850; in which he particularly refers to it as a result of the operation of antimony.

My own attention, several years ago, was forcibly drawn to this unfavourable action of the tartrate of antimony and potassa, in pneumonia especially, and it was alluded to in a paper on "the treatment of the inflammatory affections of malarious districts," which I published in the *American Journal of Medical Sciences* for July, 1844. Two cases are there given, among others of a different character; and, in regard to one of them, the following remark is made:—"In this case, an occurrence took place, which is by no means unusual with us here in the treatment of acute thoracic diseases, particularly when tartar emetic or calomel is used to any considerable extent, and more especially when they are used in combination—viz., the supervention of gastro-enteritis about the time, or soon after, a considerable amendment has taken place in the original disease."

But though I have been able to find nothing, or but little, that can be regarded as having allusion to the accident in question, where most I expected to find accounts of it—viz., among authors of the school of Rasori, in speaking of the use of tartar emetic in pneumonia, a graphic description of a similar state produced by the continued administration of calomel, may be found in the work of Golis on hydrocephalus. "Many times (he says) I saw, under these large and long-continued doses of calomel, the hydrocephalic symptoms *suddenly* disappear, and inflammation of the intestines arise, which terminated in death. Still oftener, I have observed this unfavourable accident, from an incautious use of calomel in croup—viz., where all the frightful symptoms of this tracheal inflammation, which threatened suffocation, would *vanish suddenly*, and enteritis develop itself, which passed rapidly into gangrene and destroyed the patient."

Although it is probable that it is through a local irritant action of the antimonial upon the gastro-intestinal mucous membrane, that the effect in question is brought about, the manner and circumstances of its development lead not unreasonably to the inference that a real metastasis takes place; that in addition to that irritation, which the re-

medy, probably, in almost every instance produces, where it is long used—that, for instance, which it would produce in a healthy subject—there is a superadded morbid action, transferred upon the abdominal viscera in lieu of the pneumonia, which has suddenly disappeared. It will be remembered, that, generally, it is not till after a partial subsidence of the pneumonic symptoms, that evidences of the gastro-intestinal irritation are manifested. It partakes, then, more of the character of metastasis than revulsion, though an irritant action may have determined it. Why the morbid action, from which the patient was, probably, to all appearance, in no great danger, in the lungs, should prove so frequently fatal when transferred to the abdominal viscera, is a question which naturally suggests itself. Perhaps it may be the suddenness of the invasion; perhaps the translated morbid action, operating in conjunction with a morbid state, which had already been developed in a high degree in the gastro-intestinal mucous membrane by the remedy, but which, up to the moment of the metastasis, had remained latent, in consequence of the preponderance of the pneumonic inflammation; perhaps a greater depression of the vital powers results from an equal degree of morbid action in the gastro-intestinal mucous membrane, than in the pulmonary parenchyma.

Notwithstanding this occasional unfavourable influence of the tartrate of antimony and potassa, I have felt reluctant to dispense with its use entirely in the treatment of pneumonia, in which, otherwise, its efficacy is so great; and, for some time, it has been an object with me to devise some plan of administration, by which, while its favourable operation might be secured, the former effect might be entirely, or in a great measure, avoided.

Without entering into any detail or discussion of the various and somewhat contradictory views entertained by different physicians, or sects of physicians, as to the *modus operandi* of the tartrate of antimony and potassa, I think it may at present be safely assumed that, while its sedative or contra-stimulant influence is exerted, after its absorption and commixture with the circulating mass, the unfavourable effects resulting from its administration, to which reference is here made, are consequences of its direct local action upon the gastro-intestinal mucous membrane. To be sure, according to experiments of Magendie, it would appear that its *emetic* operation is secondary to its absorption, and the result of a special affinity for, or action upon, the stomach, while in its transit through the vascular circle; but it would seem a visionary refinement in toxicology to refer the effects of which I have been speaking to an influence thus exerted, aware, as we already are, of its irritant action upon the mucous and dermoid tissues, when locally applied.

It is not at all improbable, however, that in some rare cases, the revulsive operation of the remedy on the gastro-intestinal mucous membrane may prove favourable, according to the views of Broussais; but knowing as we do, that other gastro-intestinal revellents exercise no such special control over the phlegmasiæ of the thoracic viscera, as the agent in question, as a general rule, his explanation of its *modus operandi* will, I am inclined to believe, be deemed incorrect. On the contrary, when the local effect on the gastro-intestinal mucous membrane is developed in any considerable degree, recovery, even when it follows, is retarded rather than advanced by the circumstance; not only by the additional febrile disturbance, but by the diminished absorption which results in consequence; and that when it occurs in a high degree, it occasions in pneumonia the train of alarming, and so often fatal phenomena.

Assuming that the sedative effect of the remedy through which its curative influence in pneumonia is brought about, is produced by that which is absorbed; and the deleterious effects under consideration, by that which, remaining unabsorbed, or which is not for a considerable time absorbed, remains long applied in contact with the gastro intestinal mucous membrane, by what indeed may very properly be deemed a redundancy of the article, that over and above what can be readily acted on by the absorbents, it is manifest that to secure the former and avoid the latter, no more of it should be prescribed than it is probable will be promptly taken up by these vessels, and its administration regulated in such a manner as best to secure this end.

With this object in view, I at first commenced to diminish the dose, although in no case had I ever given it in anything like the quantity recommended by many physicians of the contra-stimulant school; nor did I find the efficacy of the remedy less when I had fallen back upon about the quantity advised by many before the rise of the contra stimulant doctrine: say three, four, or at most six grains in the twenty-four hours, than when I gave it in doses twice or thrice as large; but its mischievous effects were infinitely less. It does not necessarily follow because in many cases the larger doses of the ultra contra-stimulists are tolerated for the time, and generally without any manifest ulterior mischievous effects, that they are really required.

Besides this reduction of the dose, say for the twenty-four hours, to the smallest possible quantity capable of producing a sedative influence, I have also adopted the plan of giving it in small portions, frequently repeated, so that not more will be swallowed at a time than may be promptly, at once indeed, acted on by the absorbents, rather than in larger portions at longer intervals, by which the mucous membrane would be of necessity subjected to a longer contact with a part of each portion swallowed. The method has seemed to me to be a bad one, of giving the quantity intended for the twenty-four hours at lengthened, though equally divided intervals throughout this period; but still worse the plan followed by Laennec, in some cases, of giving the entire quantity intended for the twenty-four hours, in but three or four portions, at short intervals, and then omitting it for the remainder of the day. By this method the local or revellent influence of the remedy is induced in the highest possible degree, while the sedative influence is obtained in a degree, perhaps, proportionably lessened. Generally, I give from three to six grains, according to the extent of the inflammation and the grade of febrile excitement present, in the twenty four hours, dissolved in six ounces of water. Of this solution, I give, during the day, a teaspoonful every half hour; but if the patient is disposed to sleep, that his rest may not be too much disturbed, twice the quantity every hour during the night. I have not found, as we are led to believe would be the case by some of the followers of Rasori, that the tolerance of these smaller doses is less readily established than of the larger. In some cases, where the attack is violent, in connexion with blood-letting and other appropriate measures, with the view of bringing the system as speedily as possible to some extent under the influence of the agent, I venture to give at first one or two doses, say of a third or half a grain each, of it. To favour its rapid absorption, by all means the remedy should be administered in perfect solution, in water alone; and the plan of administering it in combination with mucilage, as of acacia, flaxseed, elm, &c., is eminently calculated to lead to the result it is intended to obviate. Instead of sheathing the gastro-intestinal mucous membrane, or at least of protecting it in this way against the local irritant action of the remedy, such substances favour the latter effect, by retaining the salt for a long time in contact with the mucous surface, in consequence of the obstruction to its remedy imbibition, which they present. That absorption should take place, it is manifest that contact is necessary; consequently, nothing can be gained by placing either the absorbing surface, or the remedy to be absorbed in such a condition as to protract the process. Neither do I think the plan is a good one, of giving such fluids in the intervals; though from the universality of the practice, popular prejudice is so strongly set in its favour, that the physician who prohibits them entirely, is in danger, in case of a fatal result, of censure from the patient's friends, for the omission. The pilular is also a very objectionable form of administration; being calculated to lead to a slow absorption, and a protracted contact of the remedy, with a limited

portion of the gastro-intestinal mucous membrane; favouring thus a concentrated local action, and the development rather of its topical irritant, than of its general constitutional influence. The form of administration in complete solution, in as large a quantity of water as it is probable will be entirely absorbed in the intervals between the doses, I regard as important.

Although I have had reason to be gratified with the method above recommended of administering the remedy in question in pneumonia, it is more than I am willing to assert, that its noxious operation can be thus, in all cases, entirely obviated.

More recently, with the same object in view, in some cases I have adopted the plan of administering the tartrate of antimony and potassa in the form of enema, under the impression that its local irritant action upon the rectum would be unimportant, in comparison with that on the stumach and duodenum; hoping the while, that in adequate doses its general sedative operation might be as well secured. In the use of the remedy, after this method in pneumonia, I generally give about three grains every third hour, with fifteen or twenty drops of the tincture of opium in an ounce or two of warm water; and its controlling influence, where the enemata have been well retained, has not appeared to me appreciably less, over the febrile excitement and local morbid action, than when I have administered it by the mouth.

Although the results of my practice from this method of treatment have been highly favourable, one case stands on record in my case book in which it was principally adopted, calculated to cast a doubt upon its invariable innocuousness. Determining in the commencement of the attack to treat the case principally with the antimonial enemata, I ventured—as I thought I might do with safety, having this intention in view, and as the attack was a very violent one—upon a more free administration of the remedy by the mouth, during the first eighteen hours, than is my common practice; and it is not improbable that it was to this, in conjunction with the action of mercurials administered occasionally by the mouth during the progress of the case, that the metastasis was in reality attributable. Still I could not entirely divest myself of doubt on the subject; but even admitting in this instance an unfavourable operation from the enema treatment, I still rest satisfied of its comparative safety, in contrast with the usual method of administering the remedy by the mouth.

In the case in question, up to the evening of the fifth day, the patient was apparently doing well; the febrile excitement regularly moderating, and the organic disease gradually subsiding. At this time, a *very slight* tendency to tympanitis was discoverable, and a more rapid removal of the thoracic dulness on percussion had taken place, than between any two of my previous visits. The patient expressed himself better, however, and the general symptoms were apparently favourable. It was consequently with no slight surprise on the part of the patient's friends, as well as of a professional friend who, on this occasion, visited the patient with me, that my intimations were received of a probable speedy fatal termination. The signs and symptoms of pneumonia rapidly disappeared, the tympanitis increased, diarrhœa, thirst, restlessness, jactitation, delirium, followed by incomplete stupor of short duration, came on, and in ten hours from the time of the first symptom of the approaching change, he was dead.—*Amer. Jour.*

DIABETES IN AN INFANT.

It will appear strange that after the case of hydrocephalus in one of my own children another still more peculiar and interesting—nay unparalleled, should occur in my own domestic circle,—viz., diabetes; the subject being a male child now nearly eight months old, who, although born plump and apparently healthy, began to manifest, "a few days after birth," symptoms of diabetes, the quantity of urine voided being enormous, and truly characterized as *diabetes mellitus*, the *smell and colour of honey* being so strong as first of all to attract the attention of the mother and nurse, who, without any idea of the complaint, observed to me that the napkins smelt fragrant like honey, which remark, in fact, led me to the case, the nature of which was now (about a fortnight after birth) too evident to be mistaken; the usual concomitant symptoms being strongly developed—viz., a hot dry skin, voracious appetite, constipation of the bowels, extreme emaciation; in fact, the little patient may be termed a living skeleton. It is really wonderful that he should have survived so long in this state, having been almost in *statu quo* for nearly six months; the cranial bones being nearly as moveable as when first born. Although troubled with cough, apparently the result of repeated catarrhal attacks, there is no decided pulmonic disease, as he cries remarkably strong, nor is there any hectic tendency apparent in the countenance by night or day; the catarrhal attacks being induced, most probably, by the change of temperature to which the body is exposed, consequent on the frequent change of napkins by night and day (which average about one per hour), completely soaked. It is remarkable that not the slightest acidity has been traceable in this case, as connected with the stomach.—*Mr. Kitsell of Droitwich in Provincial Journal.*

CASE OF CROUP IN WHICH TRACHEOTOMY WAS SUCCESSFUL.

By Gurdon Buck, Jun., M.D.

S. B——, a lad, aged 11, residing in Brooklyn, Long Island, was attacked in the month of May, 1849, with scarlet fever, in the treatment of which calomel was freely administered. Profuse salivation succeeded, and destructive sloughing which involved the left edge of the tongue, the gums, and the alveolar sockets of the lower incisor teeth on the left side, and the under lip at the left angle of the mouth. Superficial abscesses also formed beneath the scalp and upon other parts of the body. At the expiration of about five weeks from the commencement of his illness, and while gradually recovering from the debilitated condition consequent upon mercurial cachexia, he was attacked with symptoms of croup, of which he was temporarily relieved by appropriate remedies. In a few days, however, the disease reappeared with increased violence, and notwithstanding the judicious and skilful treatment employed, it advanced steadily towards a fatal termination.

Under these circumstances I first saw the patient on the 8th of July, at one p.m., at the request of his attending and consulting physicians, and found his condition as follows:—He lay in a horizontal position, with his head thrown backwards, and breathing with great effort, each inspiration being accompanied with a loud, hoarse, metallic sound. His countenance was anxious, his pupils dilated, and his eyes had a wild expression; the voice was reduced to a whisper; the skin was moist; the pulse, though frequent, was not irregular or intermittent, and still retained a good degree of force. The respiratory murmur was audible and clear over the entire posterior part of the chest. The patient's situation was evidently one of imminent danger, and inasmuch as the disease had steadily advanced with only temporary abatement during the preceding forty-eight hours, in spite of efficient treatment, the only remaining resource that afforded a reasonable hope of relief was the operation of tracheotomy, without which it was scarcely possible for him to survive many hours. The operation was therefore decided upon without delay, and performed as follows:—A folded sheet being passed round the body, confining the arms to the sides, and the patient placed so as to expose the neck favourably to the light, a longitudinal incision two inches and a half in length was made over the median line, by dividing perpendicularly a transverse fold of skin, pinched up between the thumb and finger of the operator and assistant. This incision extended over the lower half of the larynx and upper part of the trachea. The subjacent layers of aponeurosis were then successively divided, and the sterno-hyoid and thyroid muscles drawn to either side. The isthmus of the thyroid body being now brought into view, was partly torn across as its upper edge, and partly pushed down, till the three or four superior rings of the trachea were laid bare. After delaying till all hæmorrhage had ceased, the opening into the trachea itself was made as follows:—A transverse slit, one-fourth of an inch in length, between the first and second cartilaginous rings, was made; the lower edge of the slit was

then seized with a clawed forceps, and a triangular piece excised with scissors curved edgeways, the incisions commencing at either extremity of the slit and meeting below at the inferior edge of the fourth tracheal ring. At the instant of perforating the trachea, the air rushed in with a hissing sound, and as soon as the opening was completed, respiration was promptly established through it, and in a short time became tranquil and easy. No embarrassment occurred from hæmorrhage into the trachea at the moment of opening it, the precaution having been taken to delay the opening until the flow of blood had ceased. The convulsive cough consequent upon establishing a new passage for the air to and from the lungs was of short duration.

The rapid transition from extreme distress and anxiety to a state of tranquil repose and comfort, was scarcely less gratifying to those who witnessed it than agreeable and welcome to the patient himself. His countenance lost its wild and anxious expression, and became calm and natural. Directions were given to wipe away promptly the viscid secretion from the wound whenever coughing occurred. At nine p.m., we found our patient had slept quietly most of the time since the operation, and his breathing had continued perfectly easy. Fearing lest the tracheal opening should become contracted by the swelling of the edges of the wound and the accumulation of the viscid secretion around its orifice, a full sized canula of the ordinary shape was introduced, and secured in place by a tape tied round the neck.

July 9th. Patient had passed a quiet night; respiration continued easy, and other symptoms were favourable; removed the tracheal tube, and after cleansing it of the tough viscid secretion lining the inner surface, replaced it as before. 11th. Progress still favourable; the rapid accumulation of viscid secretion upon the inner surface of the tube rendered it necessary to cleanse it twice in twenty-four hours. On exploring the top of the larynx with the forefinger passed back into the fauces, the aryteno-epiglottic folds were felt to be very much swollen, soft, and pulpy; the epiglottis itself was normal. Applied a solution of nitrate of silver (ʒi to ʒi) to the larynx, by means of a curved whalebone probang. 12th. Increased the strength of the solution to one drachm to the ounce, and applied it daily. The continuance of the obstruction of the larynx without perceptible abatement, showed conclusively what would have been the result of the disease if the operation had not been resorted to. 14th. Some diminution of the obstruction in the larynx seemed to have taken place. In closing momentarily the tracheal opening, patient was able to breathe once or twice through the natural passage, but not without great effort. The application of the nitrate of silver was continued till the 30th, when it was suspended for three weeks, the tube in the meantime being changed twice in twenty-four hours.

August 20th. On resuming my attendance which had been interrupted by sickness, patient was found to have improved very much in health and appearance, and to have gained flesh and strength. The condition of the larynx was as follows:—The tube being removed and the tracheal opening closed, a few words could be uttered in an audible tone, but not without considerable effort; respiration could be carried on through the larynx only a very short time, and also required very great effort. With the view of exercising the obstructed parts without removing the tube, a free opening was made at the bend of the tube through its convex side, which would allow the ascending column of air to pass up through the larynx in the act of expiration, and the reverse to take place in the act of inspiration, the outer orifice of the tube being closed. With the tube thus arranged, and *in situ*, it was found that after inflating the lungs through the tube, a very considerable effort was required to expel the air through the larynx with the external orifice of the tube closed; thus showing the existence of obstruction to the egress as well as the ingress of air through the larynx. Patient was directed frequently to repeat this experiment himself, in the hope that the expansive pressure of the ascending column of air against the walls of the larynx might aid in overcoming the obstruction. 28th. No perceptible improvement had taken place since the preceding note; the obstruction appeared to be unchanged. Resumed the application of solution of nitrate of silver (ʒi to ʒi), and succeeded in passing the sponge into the cavity of the larynx. 30th. Some improvement was now observable; patient could count from one to six, in a clear tone of voice, with the tube closed externally.

September 1st. Still further improvement has taken place; patient could count up to thirty, and breathe a few times uninterruptedly through the larynx. 5th. A sudden change of weather having interrupted his improvement since the previous date, patient was now again regaining what he had lost. Ordered iodide of potassium in solution, two and a half grains, three times a day. Stopped applications to the larynx. 11th. The improvement of the voice continued, while that of respiration did not keep pace with it; imprudent exposure to the cold wind on the roof of the house had retarded his progress. Resumed the application of solution of nitras argenti (ʒiv to ʒi) to the larynx, but continued it only a few days, after which all further treatment was laid aside.

Up to the present time (April 3, 1850) the patient, who is now submitted to your examination, has continued to enjoy excellent health. He still wears the tracheal tube, arranged in the way already described, and suffers much less inconvenience from it than would be supposed. He is a boy of great activity, participates ardently in all the out-door sports of boys of his age, and also attends school. With the tube closed he can breathe eight or ten times uninterruptedly, though before completing the number considerable effort is requisite. In using his voice he closes the tube with his finger.

In the month of October following this patient was seen, and his condition ascertained to be very much the same as when exhibited to the Academy.—*Transactions of the New York Academy of Medicine.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, NOVEMBER 19, 1851.

REMUNERATION FOR PROFESSIONAL SERVICES IN PRIVATE PRACTICE.

The observations on this subject, published in our Number for the 5th of November, have elicited the following sensible letter, to which we willingly give insertion: from the discussion of it, however embarrassing it may be, there is no escape. The terrible revolution in property which has taken place, requires an adjustment of medical fees to the new state of society which has followed it, as much as the new law which disables the dispensary surgeon from affording medical relief to any except persons having a legal right to demand it on the score of poverty. Doubtless many, both in the metropolis and the provinces, will adhere to the arrangements heretofore in operation; but many must adopt another plan, as indeed has already been done after a kind of contraband fashion:—

TO THE EDITOR OF THE MEDICAL PRESS.

"The administration of gratuitous medical aid to persons not paupers, at dispensaries, is no longer lawful, and those obtaining it are liable to be called on to pay for it if discovered. Right or wrong this is now the law, and the sooner the surgeons of Ireland look to it the better, for out of such changes will arise a new state of things. Guinea fees are out of the question in dealing with the parties who were heretofore quartered on the dispensaries for medical aid, but more moderate fees are not, and the moment has arrived when men must make up their minds as to the class of practitioner who is to enjoy them."—Medical Press, November 5.

Dear Sir,—I consider that the thanks of the provincial practitioners of Ireland are due to you for first breaking through the reserve which has been maintained on a subject of general interest, and for calling their attention to the new state of things arising out of the recent change in the dispensary laws. I have good reason to believe that you here express the views of a very large number among us who having heretofore sacrificed much of their income to the strict observance of the usage which acknowledged but two classes of patients, "the guinea and the gratuitous," now feel that it is no longer either their duty or their interest to insist on the *honorarium* as an absolute rule of practice, or to give gratuitous attendance to the numerous class who can afford to pay a more moderate fee. That this change ought and must be made will appear evident to any who reflect on

the breaking up of the old relations between subscribers and medical attendants of dispensaries, whereby thousands will be made to depend upon it for their chance of obtaining medical aid, beyond that of the country apothecary, until, as will inevitably occur, a new race of five-shilling general practitioners arise to supply the wants of society.

Nor does a survey of the past history of the profession in the provinces lead us to lament the impending change. It is true, that by the custom of the profession the practitioner was bound to refuse a fee below its standard; but it did not follow that he always obtained it; in fact, in prolonged attendances, he has seldom done so, nor did his refusal of ten shillings for ten minutes of his time at his own house enhance the scanty remuneration received for long and weary journeys into the country. It was practically evaded in the quartering on his dispensary of the servants and tenants of the wealthy subscribers, as well as of the farmers and their families, to whom he was obliged to give his attendance in return for the guinea subscription; nor did it prevent his being called upon to give gratuitous aid to those not patients of the institution who were unable to pay the required fee.

It may be a question if the change should be made privately, and by each individual having an understanding with his own patients, or publicly, and by the general voice of the profession; I cannot but think it should be done openly and by the body; that the public should know that, as it is no longer a question of a guinea or nothing, there is no longer a claim for our gratuitous attendance on such as can afford the smaller fee; that there is also an end to the sham which disgraced the dispensary system, of attending the families and servants of subscribers for a miserable pittance under the name of a subscription to the institution; that we in future expect to be paid for our attendance on the several classes of society by a scale of remuneration adapted to their circumstances, and to the time and labour they may require of us; sometimes falling below, sometimes rising above the present standard. It cannot be doubted that such a step on the part of the profession would be hailed by the public, who have often called for it, and now imperatively need it, as a wise and liberal concession to their feelings and interest. The recent act of Sir W. Somerville is felt to be a great boon, but without this act of ours its operation will be incomplete and partially prejudicial, since it makes no provision for the wants of those who will be deprived by it of the medical aid they have hitherto received; it rests with us to supply the deficiency and to make the benefits of the change of system felt alike by the profession and the public.

I hope, sir, you will continue to give your assistance to effect this object; perhaps a good mode of ascertaining the feeling of the provincial practitioners would be to call upon them to subscribe to a simple resolution affirming "the necessity of a change of the present uniform fee of a guinea and the substitution of a charge proportioned to the time and labour required of the practitioner and the circumstances of the patient."

The rate adopted will necessarily vary in different parts of the country, and it will be understood that each medical man will set his own value upon his own time: the principle for which I contend is, that he should be at perfect liberty to make his own arrangements with the public; I may, however, state that to myself, and several professional friends and neighbours, it seems that the following would be an equitable scale:—

1. For advice given at the house of the medical man on stated days and at stated hours, 5*s.* to 10*s.*
2. For a single visit in the town in which he resides, 10*s.*
3. For country visits, £1 and upwards.
4. For consultations in town £1; at a distance, £2 and upwards.

I am, Sir, yours, &c.,

A. Hudson.

Navan, November 9, 1851.

Whatever may be the tariff of fees adopted, and it probably will vary according to circumstances, it is clear that the dispensary surgeons must from the very outset in their new institutions resolutely resist every attempt, on the part of persons having no claim on the score of poverty, to obtain gratuitous medical relief at the public expense. They are now emancipated from the oppressive power which compelled them to give their valuable services, even to persons in affluence, as a conditional return for a miserable subscription; and let them not resume the yoke. The dispensary must now be most cautiously conducted as a part of the poor-law system, and with strict observance of the laws and regulations which govern that department; and any tampering with its specific application, or mixing up its administration with the business of private practice, will most assuredly subject the party who does so to dismissal, if not to penalties. All attempts to saddle the electoral divisions with the expense of medical relief for persons not paupers, by guardians, committee men, or relieving officers, must be closely watched; and if persevered in, must be brought under the notice of the guardians at large, or even of the commissioners. Everything will depend upon the firmness displayed at the outset; and any pusillanimous truckling, or collusion of doubtful nature, will assuredly be followed by a worse state of affairs than that which has hitherto existed. Now or never the surgeon must assert his right to a fair remuneration for his services, and now or never must he repudiate and renounce all collusive arrangements which made him the victim of the needy and greedy. Here is a paragraph from a contemporary something to the purpose:—

The case of Woolcott *v.* Glover, tried lately in the county court of Maidstone, is one of considerable importance to the interests of the medical profession. It is an unquestionable fact, that no class of the community performs so many gratuitous services as the members of our profession to those who require their aid. May they ever continue to assist with their charitable advice the poor and the needy! But it is the bounden duty of the governors of our public charities, as it is also of medical men themselves, to see that benevolence is not abused. Complaints continually reach us of persons applying to the various hospitals and dispensaries in London, who are well able to pay for medical advice; and in one instance a case was forwarded to us of a "lady governor," who subscribed to a large dispensary in London in order to be attended by a medical officer belonging to it. Such conduct is not only a fraud upon the charity, but is most dishonest and most unjust towards members of the medical profession. The advocates of self-supporting dispensaries have been constantly reminded of such cases, but the philanthropic zeal of some of them, and the interested motives of others, have either blinded them to the truth, or induced them to evade it. If persons in the middle class of society could be found mean enough to place themselves as patients at a charitable institution, how many would be induced to become subscribers to a penny dispensary, at which they might *command* the services of the various medical officers? Cases like that which occurred lately at the Kent Ophthalmic Hospital must be of frequent occurrence in the hospitals of London; and it behoves the medical officers of these institutions in such instances to follow the example of Mr. Woolcott, who is entitled to great commendation for the very proper and spirited manner in which he acted in the Maidstone case.—*Lancet.*

QUALIFICATION FOR SURGICAL OFFICES.

We have several letters inquiring whether certain collegiate diplomas or licences will be accepted as qualification from candidates for the situation of Dispensary Surgeon. The act provides that all persons who heretofore held dispensaries are eligible to hold them still, or to be appointed to others; and it is evident that all surgeons in Ireland, having been hitherto eligible to such offices, must so continue. How far it may be necessary or expedient to modify this rule or practice hereafter, according to the educational arrangements of the Colleges of Surgeons, may be considered; but privileges already recognized cannot be disturbed. It is evident that the attendant on our mixed medical charities must be a Surgeon, whatever else he may be; and if a surgeon he must be one *de jure* and *de facto*. No counterfeit copy of one uttered by dealers

in certificates and diplomas to serve as decoys to fill their empty benches will answer. The public, and all trustees for the sick poor declare this, and any departure from so obvious a rule must prove disastrous to the best interests of our profession. To this point we solicit the particular attention of our brethren throughout the provinces, and earnestly entreat of them to allow no appeals to their prejudices to divert them from a consideration of its importance. No man should be recognized as a physician or surgeon in this country unless duly qualified by education and the diploma of a college legally authorized to grant him the requisite licence. The door once opened to admit any other never can be closed. For many years the Dublin Apothecaries' Company, with a pertinacity highly characteristic, have laboured to foist their licence to open shop on the country as a medical qualification, and at the moment we write the medical professors of Trinity College are attempting to foist a mock diploma on it as a surgical one. These attempts may be and are treated with the contempt they deserve, but the making of them proves that no consideration of character or duty will restrain men when their personal interests are at stake. Our profession has suffered severely in public estimation by the disgraceful newspaper displays and other doings of some of its members, but let it be once established that there is no well marked line of demarcation between regular physicians and surgeons on the one hand, and the holders of mock diplomas on the other, and all claims to confidence is at an end.

GASTROTOMY SUCCESSFULLY PERFORMED FOR EXTRA-UTERINE PREGNANCY.

By Drs. Bradley and Rogers.

The patient was a negro woman, aged 28. the mother of seven children. In June, 1849, six weeks after conception, she began to complain of colic, attended with constipation. On the 10th of February, 1850, she supposed herself in labour. On examination, the os uteri was natural and the breasts were flabby. There had been no movement of the child felt since the middle of November, at which time there was milk in the breasts. A tumour filling the whole right lumbar region, extending above the hypochondriac, and below to the iliac region, and somewhat to the left of the umbilicus. There was also present considerable febrile disturbance. She was certain that she had felt the motions of the child, from the fourth or fifth to the seventh or eighth month, when she supposed it died. The diagnosis being extra-uterine pregnancy, the removal of the child was recommended.

On the 7th of February, 1851, the patient having been previously prepared, chloroform was administered. An incision was made, extending for two inches above the umbilicus to the pubes. The fœtus was found in the right Fallopian tube, fully formed and about the size of a seventh-month child. But little decomposition had taken place. It was firmly attached to the peritoneum, anteriorly and posteriorly, and latterly to the uterus. In separating the attachment, the epidermis of the child was removed at the adherent portions. After removal, the parts were carefully cleansed, and four sutures, with sufficient adhesive plaster, were used, and an opiate was ordered. Her recovery was rapid, so much so that, four weeks after the operation, it was complete.—*New Orleans Med. and Surg. Jour*

TO THE EDITOR OF THE DUBLIN MEDICAL PRESS.

Sir,—In perusing my paper, inserted in your number for 5th November, I find the following:—

Erratum.—Page 292, twenty-eight line from the bottom, "Circumscribed congestion at the *heart*" for "Circumscribed congestion at the *most*."

Your obedient servant, E. Sharkey.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE PRESIDENT and COUNCIL hereby give notice, that on Monday, the 15th of December next, at the hour of Two o'clock, they will proceed, according to the provisions of the Supplemental Charter, to elect a Professor of Practical and Descriptive Anatomy, in the room of Dr. Macdonnell, resigned.

Candidates are requested to lodge their applications at the College on or before Tuesday, the 9th of December.

By order of the Council.

H. MAUNSELL, Secretary.

College, November 13, 1851.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

THE ROYAL EXCHANGE ASSURANCE,

Incorporated A.D. 1720, by Charter of George the First.

THOMAS TROUTON, AGENT,

No. 8, WESTMORLAND-STREET, DUBLIN.

Fire and Marine Assurances on liberal terms.

Life Assurances with Bonus (which has averaged 43 *per cent.* on the Premium); or, at lower rates, without Bonus.

Moderate Premiums and a fair division of Surplus.

Age.	With Profit. £ s. d.	Age.	Without Profit. £ s. d.
20	2 0 11	20	1 17 6
30	2 11 7	30	2 7 8
40	3 6 3	40	3 1 9
50	4 11 3	50	4 5 8

Exemption by the Charter from the liabilities of Partnership.

The Security of a large Capital Stock, and the moral guarantee afforded by 131 years' experience and reputation.

The soundness of a thoroughly tested Office, with all the real improvements of modern practice.

THOMAS TROUTON, AGENT,
(Successor to Richard Purdy,)
No. 8, WESTMORLAND-STREET, DUBLIN.

SURGICAL SOCIETY OF IRELAND.

THE Meetings of the Society, for the Session 1851–2, will take place at the Royal College of Surgeons, on the undermentioned Evenings, at half-past Eight o'clock, precisely:

1851.—Saturday, 22nd November.
Saturday, 6th December.
Saturday, 20th December.
1852.—Saturday, 10th January.
Saturday, 24th January.
Saturday, 7th February.
Saturday, 21st February.
Saturday, 7th March.
Saturday, 21st March.
Saturday, 4th April.
Saturday, 18th April.

Members who intend to read Papers before the Society, are requested to inform the Secretaries of their intention on the Thursday preceding the Meeting.

When the Contributor of a paper wishes that the Secretaries should read it to the Society, he will please to forward it to them some days before the Meeting.

CHARLES BENSON,
O'BRYEN BELLINGHAM, } *Secretaries.*

CORK SCHOOL OF MEDICINE.

The Twenty-fifth Winter Session commenced on the 20th of October, 1851.

Anatomy and Physiology—H. A. Cæsar, M.D.
Surgery—W. K. Tanner, M.D.
Materia Medica—J. F. McEvers, M.D.
Botany—T. Power, M.D.
Midwifery—W. C. Townsend, M.D.
Practice of Medicine—C. Y. Haines, M.D.
Chemistry and Practical Chemistry—C. Nash, M.D.
Natural History—T. C. Shinkwin, M.R.C.S.
Natural Philosophy—E. McCarthy, Esq.
Practical Anatomy and Dissections—H. A. Cæsar, M.D. and T. C. Shinkwin, M.R.C.S.

This School, situate on the South Mall, *midway between the North and South Infirmaries*, possesses all the requisites for a complete system of medical education. Its reputation for a quarter of a century is best tested by the high character of its numerous "Alumni," not only in this city and province, but each department of her Majesty's service, and every quarter of the globe.

☞ Dr. Cæsar would receive a young Gentleman as indoor Apprentice, who would enjoy all the advantages of a comfortable and respectable home, salutary supervision, and professional education, rarely exceeded.

For particulars apply to Dr. Cæsar, South Mall.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention*; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 27th.

During the summer recess this Hospital has been greatly enlarged. Its arrangements are now such as to afford the student an opportunity of studying disease in all its forms—medical and surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every student of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are also delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct Course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, and special wards are appropriated for the reception of Eye cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's Course of Lectures upon Military Surgery is also open to the pupils of the hospital. This Course is recognized in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments.

A Lending Library of well chosen books has been provided for the use of the pupils; and a correct registry of the cases in hospital is kept by the house-surgeon, to which they have free excess.

Certificates of attendance at this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	Six guineas.
,, Summer six months	...	Four guineas.
,, Nine months	...	Eight guineas.

Physicians and Surgeons.

A. Jacob, M.D, F.R.C.S, Professor of Anatomy and Physiology, Royal College of Surgeons.
T. E. Beatty, M.D., F.R.C.S., Professor of Midwifery, Royal College of Surgeons.
C. Benson, M.D., F.R.C.S., Professor of the Practice of Medicine, Royal College of Surgeons.
W. Hargrave, M.D., F.R.C.S., Professor of Surgery, Royal College of Surgeons.
R. C. Williams, M.D., F.R.C.S., Professor of Materia Medica, Royal College of Surgeons.
T. G. Geoghegan, M.D., F.R.C.S., Professor of Forensic Medicine, Royal College of Surgeons.
J. Tufnell, Esq., F.R.C.S., Surgeon to the Military Prison.

Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, 34, York-street.

MEDICAL, LEGAL, AND GENERAL MUTUAL LIFE ASSURANCE SOCIETY.

PROCEEDINGS OF SOCIETIES.

SURGICAL SOCIETY OF IRELAND.—Nov. 22.

THE first meeting of the Society for the Session 1851–52 took place at the Royal College of Surgeons, on Saturday evening, November 22nd, and was most numerously attended. The chair was taken by Mr. TRANT, President of the College, who delivered the following

ADDRESS.

GENTLEMEN,—The period having arrived for commencing the usual annual sessional meetings of the Surgical Society of Ireland, we, as members of that body, have assembled here together this evening, not only for that scientific purpose, but also to celebrate this the 19th anniversary of its distinguished existence.

I can assure you, that, interested as we all must be deeply in the permanent success of this Society, dedicated as it is to the promotion of medical knowledge, it affords me no small degree of satisfaction in being able on this occasion to congratulate you on the prosperous career it has run, from its first commencement to the present moment—a career which, I am happy to say, has never at any time during that period received either check or obstruction in its onward progress, but has steadily advanced, creating as it proceeded a pure desire of scientific knowledge amongst its numerous members, which increased with every step it took and with every acquisition it acquired; reflecting back, at the same time, much dignity and credit on this College, which has ever been distinguished as the maternal nurse of medical literature and science, and in this instance, from its anxious desire to promote the scientific objects of this Society, and at an early period of its meetings, whilst I may say it was struggling into life, it held out to it the right hand of friendship, directing its juvenile steps with parental solicitude through the devious mazes of medical science, with that degree of zeal and success which has established for this Society the distinguished character which it now so deservedly enjoys, and thereby coöperating in carrying into effect the scientific intentions of the master-minds of those eminent individuals by whom this association was originally founded.

When I consider the different subjects which ought to belong to an address such as this, they are so numerous and important—important from their scientific bearings—that I feel it would be quite impossible for me, limited for time as we are, to enter fully into all the different topics which might be laid before you; and as there is neither time nor occasion at present for anything but casting a passing glance at some of the most important subjects as we proceed, I do not consider that I would be justified in trespassing on your time by expatiating at any length on the advantages which have been conferred on professional science through the instrumentality of reunions such as this; that being now a matter so universally admitted, that I feel it would be performing an act of supererogation on my part were I to do so, as it must have been heretofore ably and eloquently established in this room on similar occasions by some of my distinguished official predecessors.

I cannot, however, when I reflect on the importance of the subject, refrain from offering a short but favourable opinion as to some of the many beneficial results likely to proceed from well-conducted societies such as this, and which it has established itself to be, from the generous spirit of competition and friendly emulation which has invariably pervaded all its sessional meetings; creating amongst its members a degree of earnestness in the promotion of medical science which has ever been the object of this Society to organize and stimulate. And, as the dignity of our profession, and its rank in society, depends, to a considerable extent, on its scientific character—a character which it has acquired long since through the unexampled exertions of our revered and distinguished professional ancestors, who, by their well-directed scientific labours, and the vast intellectual vigour of their minds, unfolded many of the existing difficulties by which professional science was then enveloped, giving a new direction to the reasoning faculties of men on those subjects, and thereby establishing for surgery a position which it now so

creditably maintains amongst the highest departments of human knowledge, raising it from its original humble position as a manual art, to a distinguished place amidst the liberal and enlightened professions.

I feel, therefore, that in these days of onward progress, with examples such as this before us, that we, as members of a scientific body, cannot remain quiescent, and look on at the rapid strides which medical science is now making, without having produced in us a degree of emulation which must arouse our dormant faculties, and engender a desire to facilitate by our mental exertions and scientific contributions the steady progress with which professional knowledge is daily advancing—a progress to be anticipated when we consider the vast assistance which medical science has derived from the great energy with which the collateral branches connected with our professional pursuits are now so generally cultivated; inducing that ardent but humble spirit of observation and inquiry, without which there can be no success.

We must, therefore, labour if we are desirous to keep pace with the present times; we must meet increased difficulties by increased exertions, and apply our shoulders to the chariot-wheel of science, and endeavour, by our professional endowments and mental exertions (through the agency of this Society), to assist our fellow-labourers in forwarding its onward movement.

I trust, therefore, that those persons who have heretofore so nobly distinguished themselves by the lively interest they have evinced in promoting the desired objects of this Society, will not now allow their energies to relax, but persevere in the same direction they had originally marked out, and which by their well-directed exertions has assisted most materially in raising this Society to its present flattering position; and in proportion as it shall succeed in the diffusion of medical knowledge, so shall they have the satisfaction of knowing that its prosperity mainly depends upon their combined support and exertions; and much honour and credit will redound to them for the anxious care and deep interest they so benevolently exhibited in promoting the scientific objects contemplated by this Society—objects which can only be attained by the united and skilful application of scientific labours, and by which alone this great end is truly to be accomplished.

It is manifest, from the present state of professional information, that there is no portion of human knowledge more susceptible of being promoted by the combined exertions of scientific men, congregated together for scientific purposes, than ours; or a society in this country more eminently calculated to advance that all-desired object than this, from the professional importance of the different subjects which must necessarily come before it during the continuance of its sessional meetings; affording thereby an opportunity of dispassionately investigating their intrinsic merits by drawing to them the notice of persons who may have paid especial attention to the particular subject; and thus each member, according to his peculiar pursuit or means, will have an opportunity afforded him of supplying any wanting knowledge that may be required, or of elucidating any existing perplexity by which the subject may be surrounded, and the much desired results of profound investigation may also be elicited from those individuals whose professional eminence and great knowledge often engenders a degree of humility which induces them to consider that, although extensive may be their own professional acquirements, that still all men are equally capable of attaining scientific knowledge, and of appreciating its value, as themselves; and thus the matured opinions and the well-digested observations of different medical practitioners are carefully elicited, and satisfactory conclusions are frequently arrived at on some of the most abstruse professional subjects, from the able, scrutinizing, and scientific manner in which the various essays are discussed and investigated; displaying at the same time, in the various departments of medical science, facts which industry and observation had been for years collecting, and of submitting them to the trying tests of those persons who have had greater experience of the subjects from the continued attention they may have devoted to them.

There are various other matters of professional importance connected with the working of this Society which I regret I have not been able to bring before you on this occasion, and which perhaps ought to have been referred to, did time permit; but I scarcely think it necessary to detain you now on those matters, when I consider that they could not have escaped the scrutinizing observation of those talented individuals who preceded me in this chair, and who, from their known abilities, must have brought them before the Society heretofore, in a clearer and less hurried manner than I could possibly think of doing at this advanced period of the evening, as I find that the time allotted to holding the usual meetings each night is of a limited character, and consequently renders moments like the present of too precious a nature to allow me to trespass longer on your patience; it being desirable that we should proceed, with as little delay as possible, to the despatch of the more important business we have to consider during the remaining portion of this evening, and from the scientific importance of the subjects that will necessarily come before you, they must consequently claim your special attention.

It remains for me now to congratulate you on the agreeable circumstances under which we are assembled here together this evening, for an object which I am convinced we will all hail as one which must afford true gratification, when we consider it is to aid, by our scientific exertions, through this Society, the advancement of professional knowledge—an object which cannot but produce in us those elevating feelings which such a situation must necessarily inspire, especially when we consider the satisfaction and benefit likely to arise to the members of this body, to the public, and to the profession in general, from the future sessional meetings of this association.

I trust, however, that in addressing you this evening as regarded the past career of this Society, that I have not been found to have uttered anything that could be considered either too much or too flattering; and as regarded the future, that I have not exaggerated in any way, as I can assure you that my most anxious desire has been to guard myself from holding out expectations of too encouraging a nature on the one hand, or of depressing fair and legitimate exertion on the other.

Permit me, therefore, now, actuated as I am by the strongest feelings for the future prosperity of this Society, to express an anxious desire that all our scientific discussions may be conducted with that degree of good feeling and taste which has heretofore invariably marked the sessional meetings of this association; respecting and tolerating each others' peculiar opinions, and discouraging by every means in our power, anything calculated in the slightest degree to create or prolong division and controversy.

ACCOUNT OF THE DISSECTION OF A SUBJECT IN WHOM TWO POPLITEAL ANEURISMS HAD BEEN TREATED BY COMPRESSION FOUR YEARS PREVIOUSLY; WITH SOME REMARKS, AND A TABLE OF THE CASES IN WHICH COMPRESSION HAS BEEN SUCCESSFULLY EMPLOYED.

By O'B. Bellingham, M.D.,
Surgeon to St. Vincent's Hospital.

Dr. Bellingham said the case which he wished to bring before the Society on that evening was one of some interest. The patient had been the subject of popliteal aneurism in both limbs, several years previously, which had been treated by compression. Upon one side, the pulsation of the aneurism had ceased; upon the other, the compressing instruments were discontinued. The patient's death was the result of aortal aneurism. He had left directions that I should be asked to examine his body—a permission which I gladly availed myself of.

Samuel Wilson, a butcher, ætat. 34, healthy, was ad-

mitted into the Adelaide Hospital, under Dr. O'Brien, October 8, 1846, labouring under popliteal aneurism upon the left side. He had been accustomed to lift heavy weights, but could assign no cause for the disease: its appearance was preceded by cramp in the calf of the leg. The tumour exceeded a hen's egg in size, filled the popliteal space, and projected laterally, was accompanied by a strong heaving impulse, and on auscultation a loud bruit de soufflet was audible. Pressure upon the artery above emptied the sac. The patient complained of much pain shooting down the limb, which increased at night.

Compression was commenced soon after the patient's admission into hospital, the pressure being made upon the artery as it crosses the horizontal ramus of the pubis, but the inguinal glands, which were somewhat enlarged, became painful; compression was subsequently made lower down on the limb by means of two instruments, which were alternately relaxed. Pressure was maintained pretty regularly during the day, but not at night. Towards the end of December, or beginning of January, the patient returned home, taking the compressing instruments with him, which he continued to use. The pulsation ceased January 21, 1847.

The aneurism in the right popliteal space, which had existed unknown to the patient until after his admission into hospital, was smaller than the other, did not fill the popliteal space, nor project beyond it, and the bruit de soufflet was less loud in it than upon the opposite side.

The treatment of it was commenced when the pulsation had ceased in the other aneurism; it was conducted at the patient's residence, the management of the compressing instruments being left entirely to himself, except when visited by me, and the pressure was either intermitted at night or was inefficiently maintained.

January 22, 1847. Compression commenced to-day, by means of two instruments upon the lower third of the thigh.

26th. The patient says he has maintained pretty constant pressure. A small collateral vessel can be felt upon the inside of the knee, but its pulsation is very feeble.

28th. Two enlarged collateral vessels were noticed by the patient upon the inside of the hamstring tendons at each side, but they pulsated very feebly. On discontinuing the pressure upon the artery above, the pulsation in these vessels ceased.

30th. The aneurismal sac does not collapse when pressure is made upon the femoral artery, as it did at first, and it feels more solid. The collateral vessels have not increased in size. When the instruments are removed, the pulsation in the centre of the aneurismal tumour is still strong.

February 4th. The pulsation of the collateral vessels about the knee is almost imperceptible now; the aneurismal tumour feels somewhat more solid, and on pressing pretty firmly upon it the pulsation is checked. The patient was directed to apply a bandage to the limb, with a compress upon the tumour at night.

5th. The compress and bandage were omitted, and the compressing instruments applied again upon the artery above.

11th. The enlarged collateral vessels which had been felt are not now perceptible, and have not been for some days. The patient says that he has kept up the pressure regularly.

22nd. The pulsation of the aneurism is more feeble, the sac has diminished in size, and it appears to be rather more solid.

25th. When the instruments are removed, the pulsation of the aneurism is less strong than formerly, and no bruit is audible on applying the stethoscope over the tumour. A bandage was put on, and the patient was allowed to get up, as he said he was obliged to return to his employment in the course of another week. He was advised to make compression at intervals upon the artery in the thigh.

March 6th. The patient has been up every day since the last report, and is able to walk without inconvenience. He finds more stiffness in the opposite limb in which the aneurism had been cured, the tumour in which is extremely hard, resembling a racket-ball in size and shape. The pulsation of the aneurism is not stronger, nor has the tumour increased in size since the patient commenced walking about.

August 10th. The patient has worked at his employment (that of a butcher) without inconvenience, and the popliteal aneurism has not in the least increased in size; he says that the limb is stronger than the other in which the popliteal aneurism had been cured.

November 24th. The patient called upon me to-day, he had vomited a short time previously about a pint and a half of blood, of a very dark colour. He had been as well as usual previously, and had worked at his employment up to the time of this attack.

As this patient had been twice previously the subject of aneurism, the occurrence of aneurism of the aorta was not improbable; the chest was therefore carefully examined. The action of the heart was somewhat quickened, but there was no abnormal sound, neither was there any increased impulse, or morbid sound in the abdominal aorta. Over the upper bone of the sternum, however, a very loud double sound, resembling accurately that of the heart, but unaccompanied by any murmur, was heard; posteriorly also, over the spinous processes of the upper dorsal vertebræ, and in the space between the left scapula and the spine, a double sound, resembling that of the heart, was also heard. In front, upon the left side, the passage of the air through the left bronchus was accompanied by a sound as if this tube was slightly compressed. On percussion, the heart did not appear to extend beyond its normal limits, and there was no abnormal dulness at any part of the chest. The pulse at the left wrist could not be felt, owing to an injury which the patient formerly met with.

25th. The hæmatemesis has diminished, only about a wineglassful having been vomited since yesterday; the stools resemble tar in appearance; face pale; tongue clean; appetite diminished; some thirst; urine natural. The patient complains of a swimming in his head on sitting up, and nearly fainted on getting out of bed.

27th. The vomiting has not returned; the stools, however, have still the same appearance, and closely resemble tar.

29th. No motion from the bowels for the last two days; the pulse has come down to the natural standard; he feels stronger; appetite improved; less thirst.

In a few days afterwards the patient was sufficiently well to return to his employment.

August 18, 1848. The patient was seen to-day; he has remained perfectly well. The pulsation continues in the aneurism in the right ham, but it causes him no inconvenience.

In about a year afterwards, the patient came to me complaining of very severe pain at the upper part of the chest. On examination, signs of aneurism of the arch of the aorta were sufficiently evident, but there was no external tumour. The aneurism in the ham has not increased in size, but appears, if anything, to be smaller; he has continued to work at his employment, and declined coming into hospital, although informed of the dangerous nature of the disease.

September 1, 1850. The thoracic aneurism has increased in size, and a small pulsating tumour is now felt above the sternum; the left sterno-clavicular articulation is also more prominent than natural, and an impulse is perceived at this point, as well as below it in a circumscribed space. The impulse is double, and pretty strong. On auscultation, a ringing double sound is heard, without any bruit. He complains of pain over the tumour, extending particularly to the left shoulder, and felt much between the clavicle and trapezius muscle; also occasionally of pain in the back of the neck, extending up to the back of the head. He has some difficulty in swallowing solids, which is referred to the site of the aneurism; this latter symptom has been only experienced for about a week, within

which period he says the tumour has increased so as to be perceptible to the eye; he feels as if a tight cravat was round his neck at this part. He coughs only in the morning, and either coughing or sneezing causes increased pain in the tumour, passing backwards to the shoulders.

He has worked at his employment since I saw him last, with the exception of a few weeks; the pain, he says, is always most severe after hard work, but it does not prevent him from sleeping. His general health is very good, and his appetite is unimpaired.

The left lower extremity in which the popliteal aneurism had been cured by compression is, he says, as strong as ever; no tumour is perceptible now in the popliteal space. The aneurism in the right ham has diminished in size; its pulsation is slight, and no bruit is audible in it on auscultation.

November 26th. Patient is now suffering under extreme dyspnœa, distress, and pain. He had worked up to about a fortnight ago, when he was attacked with a very severe fit of coughing, and fell to the ground in a state of partial insensibility, from which, however, he quickly rallied. Since then he has had several equally severe fits of coughing, some of which, he says, have lasted for two hours without intermission; during them, he says, his face becomes black, and he loses consciousness for a time. Since the first attack of severe cough, he has never been free from dyspnœa and distress. He is unable to lie upon either side, or upon his back; is obliged to be propped up in bed by pillows, or to lean forwards; the latter is the easiest position. If he falls asleep, he is awakened by frightful dreams, and a feeling of impending suffocation. He suffers pain, referred to the sternal region and to the dorsal spine, which is constant and severe. The neck is emphysematous, particularly upon the left side. The aneurism points above the sternum and left sterno-clavicular articulation; its surface is not discoloured; the impulse of the aneurism is double, and it yields a double sound on auscultation, without any bruit. A harsh sibilant râle is audible in the same situation, evidently from pressure on the left bronchus; the voice is hoarse, and the cough is raucous. He says he has no difficulty in swallowing now. Pulse small and feeble, intermitting occasionally.

Upon the side on which the popliteal aneurism had been cured, no tumour can be felt; upon the other side the pulsation is still distinct; the tumour appears to be smaller than when examined last.

30th. Dyspnœa diminished; the fits of coughing have been less frequent; he is able to assume the recumbent posture, and sleeps better; the congestion of the face has much diminished.

December 6th. The patient has no pain now; he rests pretty well; the cough is less troublesome; the appetite has improved; the congestion of the face has disappeared, and the patient has been able to be out in the open air, and to walk without much inconvenience.

26th. The paroxysms of coughing continue to be severe, but are less frequent, and the patient does not become insensible in them. The external tumour has not increased, and the patient is able to be in the open air for a short time every day. He says that on two or three occasions lately he has, after coughing for some time, expectorated a substance resembling a bit of raw meat.

Jan. 15, 1851. The patient has been suffering recently from attacks of vertigo, with double vision, when he is obliged to seize upon something near for support; he says the sensation of double vision ceases when he closes one eye with the hand; he also suffers occasionally from vague sensations of terror, which have been so distressing as to make him wish to throw himself out of the window of his room; the respiration is raucous, and this is audible without the application of the stethoscope.

February 6th. The patient has suffered much since the last report from cough and dyspnœa, owing to inability to expectorate the mucus which accumulates in the bronchial tubes, and he is obliged to sit up in bed during great part of the night; when he falls asleep, he awakens in terror, with a feeling of impending suffocation; the thoracic aneurism has not enlarged externally; the pulse in right wrist is extremely feeble, sometimes almost imperceptible.

March 3rd. The patient has been rather better until within the last two days; the dyspnœa and restlessness are now extreme; the respiration is loud and raucous, and the extremities are cold.

15th. The patient has rallied again, and the restlessness has diminished.

29th. The patient has suffered very much from dyspnœa within the last fortnight, has been confined to bed for part of the time, and has been unable to leave the house. This has diminished in some degree now, and the patient is in about the same condition he was a month since. The thoracic aneurism has not enlarged externally at all.

April 7th. Patient walked to my house to-day; he is suffering very much from dyspnœa and cough; the breathing is noisy, a mixture of a wheezing with a raucous sound, which is heard without applying the stethoscope, and at a distance from him; he says he finds great difficulty in expectorating; he coughs for a long time, and is easy after expectoration for a few moments: he describes the expectoration as dark-coloured, and sometimes rust-coloured; he is continually teazed with the feeling of wanting to expectorate; he cannot cough loudly, being unable to take in much air in inspiration; and after the fit of coughing he suffers from a sense of constriction over the middle and lower part of the chest with pain; he says he has always some pain here.

The aneurism has not increased externally; the pulsation is evident, but not strong, the sound double, and no murmur accompanies either sound; his appetite is unimpaired, and he gets sleep for a few hours every night.

9th. The patient is unable to leave his bed; he is sitting up in it, and suffering greatly from dyspnœa and from pain and constriction across the lower part of the chest in front; he finds very great difficulty in expectorating, and has only been able to get up a small quantity of a darkish viscid and partly rusty-coloured fluid; he is afraid to cough, as it increases the pain; the face has an anxious expression, but is not congested; the surface of the body is perspiring; the feet were cold, but are not now; no pulse at all can be felt in the right wrist; in the left the pulse is absent in consequence of an injury.

The patient died at seven o'clock this evening, having suffered severely for several hours from dyspnœa, but preserving his consciousness to the last.

Post-mortem examination.—The heart of full size, rather flabby, thickly coated over its surface with fat. A white patch on the right ventricle. The thoracic aneurism, which was of the size of a large orange, sprung from the transverse portion of the arch of the aorta, rose slightly above the sternum, and extended on each side under the first bone of the sternum beyond the sterno-clavicular articulations; it was firmly adherent in front to the sternum and apex of the left lung; behind it pressed upon the bifurcation of the trachea and left bronchus, and slightly upon the right. Its interior was in great part filled up by fibrine in concentric layers, the outermost of which had a buff colour. The aneurismal sac had not given way, and the patient died evidently from the impediment to the respiration, caused by the pressure of the aneurism upon the bronchial tubes and recurrent nerve on the left side.

The artery and vein of the left lower extremity, on which side the popliteal aneurism had been cured by compression, were removed from the groin to the popliteal space. The femoral vein had undergone no change in any part of its course, and was unaltered from the inguinal to the popliteal region; its valves perfectly natural; it was pervious over the obliterated part of the artery in the popliteal space. The artery was pervious until it reached the site of the original popliteal aneurism; no remains of the aneurismal sac were seen, but the tube of the artery was obliterated at this point, and converted into a solid ligamentous cord for the space of two inches and a half.

On the right side, in which the aneurism had continued to pulsate up to the last time it had been examined—viz., about three or four weeks before the patient's death, the aneurismal sac was seated low down in the popliteal space, was scarcely as large as a walnut, and sprang from the posterior aspect of the artery; it had a very solid feel; on laying it open the coats were very tough, cutting almost like cartilage. Its interior was in great part occupied by fibrine, deposited in concentric layers. A small space in its centre contained a recent dark-coloured clot. The artery above was of the normal size; below the sac it was contracted. The vein ran over the back of the sac, and was quite unaltered in appearance.

OBSERVATIONS.

These pathological specimens illustrate in the one limb the mode in which compression effects the cure of aneurism, and in the other, the subsequent changes which ensue by which the recurrence of aneurism at the same part of the artery is effectually prevented.

This patient lived above four years after the treatment of the two aneurisms in opposite limbs; upon the side that the aneurism had been cured, and where, after the cure, a solid hard tumour, of the size and shape of a racket-ball, marked the site of the aneurismal sac, we now find no remains of an aneurismal sac, the sac and the artery at the part are consolidated into one, and merely a solid rounded ligamentous cord marks the site of the aneurism and of the part of the obliterated popliteal artery from which it sprung.

In the opposite limb where the compression was kept up for a much shorter period, and where the aneurism did not cease to pulsate, we find the aneurismal sac greatly diminished in size, its walls very thick, its interior nearly filled by fibrine, and the artery at the part not obliterated, but permitting a current of blood still to pass through it.

On previous occasions, I have had the opportunity of exhibiting to the members of the Society preparations illustrating the results of compression for the cure of aneurism from subjects who died of other diseases, either subsequent to the cure of the aneurism or before the pulsation had ceased. The present differs from any hitherto recorded, and is, perhaps, more important, as it bears upon a point which we had not the opportunity of determining heretofore, while it tends, as much as any single case can, to confirm all that has been said of the advantages of this method of treating aneurism.

In the details of this case, I have said that, after compression had been employed for a time upon the right lower extremity, it was discontinued before the pulsation of the aneurism had ceased, in consequence of the patient being obliged to return to his employment. Notwithstanding that the pulsation continued, the tumour, not only did not increase subsequently, but actually diminished in size, although the patient had to work at a very laborious employment, in which he was obliged to lift and carry heavy weights; and during upwards of four years that intervened between the period at which the pressure was discontinued and the patient's death, it never caused the slightest inconvenience, and he continued to work until the enlargement of the thoracic aneurism compelled him to desist.

The post-mortem examination shows why this was so; we find the aneurismal sac contracted and diminished in size, its parietes much thickened, and its cavity in great part filled up by fibrine deposited in concentric layers. A small portion of its interior still permitted the entrance of the blood which passed down the popliteal artery, the pulsation of which communicated to the sac gave the impulse which was felt at the part during the patient's life.

It is a point of some interest to determine whether an external aneurism can be considered to be cured, although the channel of the artery at the seat of the disease is not obliterated, and a current of blood continues to pass through the vessel. We know that when aneurism of the arch of the aorta undergoes a spontaneous cure, the sac alone is filled up, while the artery for an obvious reason continues pervious afterwards. Now, the examination of this preparation, combined with the history of the case, afford evidence that popliteal aneurism may be so far cured that the sac can scarcely enlarge again, although there is no obliteration of the artery at the seat of the disease, and likewise that this desirable result may be brought about by making compression upon the artery on the cardiac side of the sac.

The cause of the enlargement of an aneurismal sac in any situation is evidently the distension from within, caused by the impulse communicated to the blood by the systole of the left ventricle. If this distension can be diminished, or prevented altogether, the aneurismal sac cannot enlarge, but it will, on the other hand, rather diminish in size. Now, by making pressure upon the artery leading to an aneurismal sac, we can take off this distension, and render the sac quite flaccid, and by continuing the compression we can maintain the sac in this state for an indefinite length of time. Moreover, when the current of blood through the sac is materially diminished in force, velocity, and volume, another agent almost always comes into operation, the fibrine of the blood in its passage through the sac is deposited upon its interior, by which the parietes of the sac are still further strengthened.

It would appear, indeed, from the results of one or two cases, where the disease was of very recent origin, that when compression upon the artery above is steadily maintained, the aneurismal sac may gradually shrink until reduced to a very small size; and if the precaution is taken of not allowing a full current of blood to pass down the artery for a certain period, the remains of the shrunken aneurismal sac ultimately are scarcely to be felt, particularly if its site was the popliteal space or Hunter's canal, where the vessel lies at some distance from the surface.

It can scarcely then, I think, be doubted, that aneurism in an extremity may be so far cured that it can neither enlarge again nor give way, although the blood continues to pass through the artery from which it springs, and an impulse continues to be felt at the part, owing to the pulsation of the artery being communicated to the sac. In the present case, there was an interval of above four years between the discontinuance of compression and the death of the patient, during which time, although the pulsation continued, the patient was able to follow a laborious employment, and never suffered the slightest inconvenience from the aneurism. Indeed it is not improbable that the femoral artery has been unnecessarily tied in some cases, at least under similar circumstances, where, if a little delay had been permitted, it would have been found that the aneurism had no disposition to increase in size.

Before dismissing this subject, I may allude to a strange admission made by an Edinburgh reviewer in a notice of Mr. Tufnell's work and mine, in the July number of the *Edinburgh Medical and Surgical Journal*. The writer confesses to be unable to comprehend the distinction between the process by which the deposition of fibrine and the formation of a coagulum in an aneurismal sac take place.

"There is a strong temptation (the writer says, p. 227) to ask what is the difference between causing the coagulation of the contents of an aneurismal sac and the deposition of fibrine within the sac? Is fibrine deposited without coagulation? Is not the deposition of fibrine a species of coagulation? If coagulation take place, is fibrine not deposited? We must admit our inability to perceive the distinction here attempted to be made. If the contents of an aneurism are coagulated, we think that the deposition of fibrine has either already taken place, or must speedily follow. All this, nevertheless, we submit in deference to Dr. Bellingham, who, probably, has some mode of showing the difference between the two processes."

I should have thought that no one who had had the opportunity of examining cases of aortal aneurism could have failed to perceive the difference between the laminæ of fibrine which line the interior of the sac and the loose coagula of blood which occupy its centre; or could have supposed that there was any analogy between the processes by which they are developed; the former being the result of a vital process which had been carried on during the patient's life, the latter a mere post-mortem occurrence, the result of the stagnation of the blood after the circulation has ceased.

Indeed, I do not believe that pressure upon the artery leading to an aneurism by the instruments ordinarily in use can cause the coagulation of its contents; and when coagulated blood is found in the sac after death, I look upon it as a post-mortem appearance. But if we had no other evidence, the preparations upon the table prove that the deposition of fibrine in an aneurismal sac will be brought about by applying compression to the artery above. We know, too, that when this deposition of fibrine begins to take place, the sac, which before was readily emptied of its contents, and became flaccid when compression was made upon the artery above, now no longer does so, while its outline becomes distinct. We know, likewise, that this desirable result may ensue within a few hours from the commencement of the treatment, and that when it does occur it is a most favourable sign, as it indicates that the process by which the aneurism is to be cured has been set up in it.

It is not necessary to delay further upon this point; I have alluded to it, because I believe the writer in the *Edinburgh Medical and Surgical Journal* is by no means singular in his opinion; as the two substances, fibrine and coagulated blood, although so unlike one another in appearance, are continually confounded under the same name, and much inconvenience necessarily is the result of such a loose nomenclature.

The preparation from the opposite limb of this patient, in which the aneurism had been cured, is also of some interest, as being an additional example of the subsequent changes which ensue after the cure by compression, by which Nature effectually prevents the recurrence of aneurism at the same part of the vessel; as well as because it shows in some degree within what period these changes are brought about. The treatment of the aneurism in this limb was, as I have remarked, rather tedious, extending over a period of three months; after the cure, the site of the aneurismal sac was marked by a very solid hard tumour, resembling a racket-ball in shape and feel—a proof that the sac was filled with solid fibrine. About three years subsequently, upon a careful examination of the limb, no trace of this tumour remained; and now, after four years, we find that the aneurismal sac and the fibrine with which it was filled, have been entirely absorbed, and merely a solid ligamentous cord marks the site of the obliterated popliteal artery and aneurismal sac.

The last point illustrated by this preparation to which I wish to call attention is the condition of the femoral vein. It will be seen that this vein, throughout its whole course in the thigh, as well at the points at which the compression had been made, as at those where no pressure had been applied, preserves its natural healthy appearance; its valves are sound, there is no thickening of its coats, and no alteration of any kind is perceptible either upon its exterior or in its interior. Now, the treatment of the aneurism in this limb extended, as I have said, over a period of about three months—viz., from the middle of October to the middle of January; and during much of that time the pressure was made upon the middle and lower third of the thigh, where the artery and vein are very closely united, and the latter was of course necessarily compressed with the former.

It has been gravely proposed that in using pressure for the cure of aneurism, the pad of the compressing instrument should be so applied as to avoid making pressure on the femoral vein; any one, however, who has dissected the parts must know that this would be utterly impracticable, and every one who has tied the femoral artery knows that one of the chief difficulties in the operation consists in avoiding injury to the vein in consequence of its close proximity to the artery; indeed Mr. Porter has shown that, in cases of popliteal aneurism, "the femoral vein is always more closely adherent to the artery than in the healthy subject;" and this is evidently the case in the preparation before us.

I have myself had the opportunity of examining the condition of the femoral vein after the cure of popliteal or femoral aneurism by compression in several instances in addition to the present; and in none did this vein present the slightest change, proving that it bears pressure equally as well as the artery, and that if the treatment is properly conducted neither vessel can suffer any injury from the compressing instruments.

In a paper which I read before this Society on a former occasion, I gave a list of the cases of aneurism which had been treated by compression up to the date of that communication. As it may not be without interest to follow up this subject, I have drawn up the following table of the cases that have been published, where this method of treatment has proved successful, commencing with the case of popliteal aneurism treated by Dr. Hutton in the Richmond Hospital in October, 1842, and bringing it down to the present day; distinguishing the cases according to the situation of the aneurism, and giving under separate heads the age, sex, and occupation of the patient, the name of the hospital or other locality where the treatment was conducted, the name of the surgeon who had the management of the case, and of the journal in which it was published, the result, and occasional observations.

LIST OF CASES OF POPLITEAL ANEURISM SUCCESSFULLY TREATED BY COMPRESSION BETWEEN 1842 AND 1851.

Surgeon's name.	Sex.	Age	Occupation.	Where treated.	Where reported.	Result	Observations.
1. Hutton.....	Male	30	Labourer	Richmond Hospital	Dublin Medical Press	Cured	
2. Cusack.....	Male	55	Tanner	Steevens' Hospital	Dublin Medical Press	Cured	
3. Bellingham	Male	32	Servant	St. Vincent's Hospital	Dublin Medical Press	Cured	This patient subsequently laboured under femoral aneurism in the opposite limb, which was also cured by compression. He died of aortal aneurism.
4. Harrison ...	Male	29	Carpenter	Jervis-street Hospital	Rept. Brit. Association	Cured	
5. Kirby	Male	28	Baker	Jervis-street Hospital	Dublin Medical Press	Cured	
6. Allan.....	Male	32	Seaman	Haslar Hospital	Lancet	Cured	
7. Cusack.....	Male	26	Gentleman	At patient's residence	Dublin Medical Press	Cured	This patient has died since of cerebral disease.
8. Greatrex'...	Male	27	Soldier	Regimental Hospital	Proc. Med.-Chir. Soc.	Cured	
9. Porter	Male	29	Tailor	Meath Hospital	Dublin Quarterly Jour.	Cured	
10. Porter	Male	20	Medical man	,, ,,	Dublin Quarterly Jour.	Cured	This patient died subsequently of aortal aneurism.
11. Jolley	Male	38	Labourer	Torbay Dispensary	Provincial Med. Jour.	Cured	
12. Ferrall.....	Male	32	Labourer	St. Vincent's Hospital	Dublin Hospital Gaz.	Cured	
13. Macdonnell	Male	32	,, ,,	Richmond Hospital	Dublin Medical Press	Cured	This patient had been operated on some years previously for popliteal aneurism in the opposite limb.
14. Dartnell....	Male	38	Soldier	Gen. Hosp., Fort Pitt	London Medical Gaz.	Cured	
15. Cusack	Male	33	Medical man	Steevens' Hospital	Dublin Quarterly Jour.	Cured	
16. Humfrey ...	Male	43	Soldier	Mil. Inf. Phœnix Park	Dublin Medical Press	Cured	
17. Storks	Male	32	Tailor	At patient's residence	Lancet	Cured	
18. Ferrall.....	Male	37	,, ,,	St. Vincent's Hospital	Dublin Quarterly Jour.	Cured	
19. Storks.....	Male	24	Brewer	At patient's residence	Lancet	Cured	
20. O'Brien.....	Male	34	Butcher	Adelaide Hospital	Dublin Medical Press	Cured	This patient had aneurism in the opposite limb, and has died since of aortal aneurism.
21. Armstrong	Male	26	Sailor	Naval Hosp. Plymouth	Lancet	Cured	In this case the compression was made directly upon the aneurismal sac.
22. Tufnell.....	Male	27	Sawyer	At patient's residence	Dublin Medical Press	Cured	
23. Cusack.....	Male	30	,, ,,	Steevens' Hospital	Dublin Quarterly Jour.	Cured	
24. Tufnell.....	Male	28	Sawyer	At patient's residence	Dublin Medical Press	Cured	Nos. 22 and 24 refer to the same patient; he subsequently laboured under femoral aneurism, which was also cured by compression.
25. Hutton.....	Male	32	,, ,,	,, ,,	Dublin Medical Press	Cured	In this case compression was made for seven hours and a half, when the pulsation ceased.
26. Banon	Male	27	Labourer	Jervis-street Hospital	Dublin Medical Press	Cured	
27. Bellingham	Male	44	Labourer	St. Vincent's Hospital	Proc. Med.-Chir. Soc.	Cured	In this case the pulsation ceased after compression had been maintained for twenty-three hours.
28. Rodgers....	Male	47	Sailor	New York Hospital	Trans. Amer. Med. As.	Cured	
29. Mütter.....	Male	41	Bookkeeper	New York Hospital	do. do. do.	Cured	
30. Knight.....	Male	48	,, ,,	New York Hospital	do. do. do.	Cured	The compression was made in this case by the fingers of relays of assistants.
31. Hosack.....	Male	55	,, ,,	,, ,,	New York Journal	Cured	In this case the artery had been tied some time previously but pulsation had returned in the sac.
32. Paget.....	Male	27	Surgeon	,, ,,	London Medical Gaz.	Cured	
33. Thompson,	Male	30	Boatman	Tyrone Infirmary	Medical Times	Cured	
34. Ward.....	Male	45	Lighterman	London Hospital	Lancet	Cured	
35. Bennett.....	Male	30	Blacksmith	,, ,,	New York Journal	Cured	In this case the pressure was made directly upon the tumour.
36. Wood.....	Male	33	Carman	Bellevue Hospital	New York Journal	Cured	
37. Wood.....	Male	30	Carpenter	Bellevue Hospital	New York Journal	Cured	
38. Humphrey,	Male	24	Sailor	Addenbrooke's Hosp.	Provincial Med. Jour.	Cured	In this case the pulsation ceased after compression had been maintained for fifteen hours.

LIST OF CASES OF FEMORAL ANEURISM SUCCESSFULLY TREATED BY COMPRESSION BETWEEN 1842 AND 1851.

CASE OF ANEURISM OF ANTERIOR TIBIAL ARTERY SUCCESSFULLY TREATED BY COMPRESSION.

Surgeon's name.	Sex.	Age	Occupation.	Where treated.	Where reported.	Result	Observations.
1. Alexander...	Male	,,	Gamekeeper	,, ,,	Edin. Monthly Jour.	Cured	Traumatic aneurism from gunshot injury.

It will be seen that the foregoing table includes fifty-four cases of popliteal and femoral aneurism—viz., forty of popliteal, and fourteen of femoral; three cases of brachial aneurism; four of radial or ulnar aneurism; and one of aneurism of the anterior tibial artery, I have not admitted any case into this list where the patient was not *cured*, and did not live for some years afterwards. I am aware that it does not include every case which has occurred during the period in question, as some have not been published, and perhaps a few others have escaped my notice, or have appeared in journals to which I had not access.

Mr. TUFNELL observed, that the value of compression as a means of curing aneurism was well illustrated by the interesting case narrated by Dr. Bellingham. During the progress of the treatment, he had frequent opportunities of seeing the patient; and the conclusion he drew from the case was, that it afforded an additional assurance to the surgeon that, although he might sometimes be foiled for a while in treating aneurism by compression, yet he would not on that account be obliged to resort at once to the ligature, unless the sac of the aneurism manifested a disposition to increase.

EASY MODE OF REDUCING A DISLOCATED FEMUR.

By Dr. MAYR.

DR. FISCHER of Cologne, published in *Casper's Wochenschrift*, November 1, 1849, an account of his mode of reducing dislocation of the femur, and which consists in flexing the femur to an acute angle with the trunk, and impressing upon it gentle rotatory movement while in a state of adduction if dislocated on to the pubes, and of abduction if dislocated on to the ilium. Dr. Mayr, without being then aware of this procedure of Dr. Fischer, resorted to it in a case that occurred lately to himself. A man, æt. 31, dislocated his right femur upwards and backwards; and after repeated attempts at reduction, even by the pulleys, had been made, the author was called in on the 13th day after the accident. After he had in vain tried the ordinary plan of extension and counter-extension, he resorted to the following means. The opposite limb and the pelvis were fixed, the operator flexed the femur upon the trunk, and, passing one arm under the ham while he grasped the calf with the other, he imparted rotary movements of gradually increased strength to the limb. As soon as he perceived a greater mobility of the head of the femur, he brought the limb into a state of strong abduction; and when, still continuing the rotation, the head had approached the acetabulum, he was able, by a rapid and strong pull inwards, to slide it into its pan, which it entered with a loud noise. The gentle rotatory movements mentioned by Fischer did not succeed here, all his force being required in their production, which may be probably due to the time the bone had remained unreduced.

The anatomical structure of the parts also recommends this procedure. In front of the thick edge of the acetabulum, the under surface of the ilium forms a perceptible depression, and if the directions given in the manuals are followed, of making the traction obliquely from outwards inwards, and somewhat from behind forwards, be followed, the head of the bone must meet in this depression with a considerable obstacle to its progress. This sometimes even invincible obstacle appears to be avoidable by resorting to abduction.

Mr. Clark of Southampton, in referring to the above communication, states that he published a similar process seven years since in the *Lancet* and *Provincial Medical Journal*. The case was that of a muscular man, aged 30, who, from an accident on shipboard, had dislocated the left femur backwards. The head of the bone seemed determinedly fixed on the dorsum ilii, so as to resist effectually all our attempts to dislodge it by continued traction in the usual way, when it occurred to Mr. Clark that the manipulation by which we disengage the leg of a fowl, for example, in carving, was just the kind of action wanted in this case. The same abduction which brought the head out of the acetabulum forwards in one case, would in the other raise it from behind the acetabulum, and place it in a position to fall readily into its natural cavity, and this without having any powerful muscular action to overcome.

He therefore placed the patient supine on the bed, and, by a towel round the pelvis, fixed to the opposite side of the bedstead, with the help of assistants, kept these bones immoveable. He then drew up the left foot till it rested against the inside of the other knee, where an assistant held it.

In this state, it is obvious, that the head, neck, and shaft of the femur are all on the same plane, which also intersects the acetabulum, so that any motion of the extremity of the bone outwards must necessarily move the head of the bone in the desired direction. Applying, then, his right hand upon the trochanter major, he gradually abducted the knee with the left, using the slightest effort, when, with an audible start, the reduction was at once accomplished.—*Casper's Wochenschrift* and *Med. Times*.

PHARMACY IN SWEDEN.

THE superintendence and inspection of the pharmaceutical as well as of the medical establishments in Sweden are committed to the charge of a Collegium Medicum, whose members are nominated by the King; and every candidate for this office must be a Doctor of Medicine, whose degree has been obtained by passing an examination.

APPRENTICESHIP.—Any youth who may wish to enter as apprentice in an apothecary's shop, must be fifteen years of age, and ought to have gone through a school-course of history, geography, mathematics, Latin, and modern languages.

ASSISTANT, OR PHARMACIÆ STUDIOSUS.—The apothecary must announce the name of the apprentice for registration in the Collegium Medicum, and provide for his instruction in botany, chemistry, and pharmacy during the apprenticeship, which lasts from three to four years; and after which time the student is authorized to pass an examination in botany, chemistry, pharmacy, Latin, and modern languages. This examination must be passed in Stockholm, in the Apothecaries' Society, and in the country before the official physician of the province, together with the apothecary who is the master of the apprentice. After this examination his oath is taken in compliance with the law and the official pharmaceutical regulations, and he is now declared *Pharmaciæ Studiosus*, and capable of exercising the functions of an assistant in a shop, and also answerable for the prescriptions prepared by him; and by way of a check he must always sign his name to the label of the prescription. (The apprentice or scholar is not answerable, and in consequence not allowed to prepare any prescriptions, he may sell innocent medicines only, as elder and chamomile flowers, juniper-berry, gummi acaciæ, &c.)

PHARMACEUTICAL INSTITUTION.—After serving as an assistant in a shop for three years, and producing a testimonial of the fact, he may now enter as pupil at the Pharmaceutical Institution in Stockholm, and there attend the lectures which are read in botany, materia medica, and pharmaceutical chemistry, from the beginning of October to the end of May, with a few weeks vacations at Christmas. At the same time he must work two days a week in the operations of the laboratory. The fees for the lectures and the course in the laboratory are together about £1. The pupil has free admission to the lectures in zoology, botany, materia medica, and chemistry at the Royal Caroline Institution, and to the excursions of the assistant professor of botany, which take place during the summer months, May, June, July, and August, in the environs of Stockholm. After finishing the course in the laboratory, the duration of which depends upon the capacity of the pupil, he may request a private trial by the professors in

the prescribed branches of science—viz., botany, zoology, materia medica, theoretical and pharmaceutical chemistry, and toxicology. If he can present in the Collegium Medicum a certificate from the professors of their satisfaction with the trial, a day will be appointed for examination, which is conducted by two professors at the Royal Caroline Institution, and two of the apothecaries in Stockholm before a member of the Collegium Medicum. During the examination, whoever wishes, is allowed to be present, and all the questions are registered in a book kept for that purpose, and a note made whether or not the answers are correct. And the examiners express the merits of the candidates by the following different terms: *laudatur*, *cum laude approbatur*, *approbatur*, *cum approbatione admittitur*, and last of all, *admittitur*. The examination is not passed unless the candidate receive the approbatur of all the examiners.

Provisor and Apothecary.—After the examinee has taken an oath before the Collegium Medicum to comply with the laws and pharmaceutical regulations, he is declared "Provisor and Apothecary," and obtains a diploma to that effect. He is now at liberty to purchase by agreement an apothecary's shop, if one becomes vacant, or through nomination, if a new one is required in any part of the country. The right of dispensing medicines in a shop, properly procurable by personal permission from the government, and which should cost only about £4 or £5 for the diploma, has become a traffic, and the price has gradually risen to such an extent, that at the present time the *privilegium*, or good-will of one of the best shops, is sold for about £3000—a sum beyond the reach of a poor though clever student. Those who have been interested in the success of pharmacy in Sweden, have proposed to mortgage the privileges by a loan; but their benevolent endeavours have been stranded by the difficulty of procuring so large a sum of money necessary for mortgaging the privileges over the whole of Sweden. When a person through purchase or inheritance has become possessed of an apothecary's shop, he must announce it in the Collegium Medicum in order to obtain from the government confirmation of the privilege for himself. If in any part of the country a new shop is required, the Collegium Medicum announce it, and propose three of the most deserving candidates. The government nominates one of them. It is for the most part in country places, at a distance from any town, that new apothecaries' shops are allowed for the convenience of the public. In the larger towns, on the contrary, they are rarely permitted. The number of apothecaries' shops in Stockholm is fourteen, to a population of 90,000. No new shop has been permitted during the last twenty years, as the number has been found more than sufficient. For in Sweden, as in many other countries, it is observed that the larger number of inhabitants and the fewer shops the better are the medicines. The apothecaries have, in consequence, a sufficient competence ensured in their calling, and are not compelled to enter into other trades. Hence it is they love their profession, and by dispensing medicines of the best quality, strive to obtain the confidence of the authorities and the public. On the contrary, if the number of shops is very large—or, still worse, unlimited—the apothecary or chemist cannot gain a subsistence from his profession, and is, therefore, obliged to seek in other trades what he cannot find in his own; and pharmacy, instead of being the main object, is reduced to an insignificant rank, and reflects no credit upon its followers. Under such a system, if each apothecary train up one or more assistants, the number of candidates for shops will in time become extravagantly large, and the difficulty of controlling them increases in the same proportion. (Some of the apothecaries in Sweden have endeavoured in consequence, to employ assistants only, and no apprentices, in order to obviate too great competition).

The Apothecaries' Shops (Apothek).—The shops in the towns are for the most part large, and internally are often arranged with considerable elegance. The laboratory, according to the regulations, must contain a steam apparatus for preparing decoctions, extracts, aromatic oils and waters, &c. Decoctions and infusions must be prepared *extempore*. Tinctures must be kept in a room in which the temperature is not under 15 deg. Celsius, in order that the dissolved materials may not be precipitated by the cold. Native vegetables must be renewed every year, and the old stock destroyed. The best medicines, if there are several kinds in commerce, must always be written for. Every shop has a sign of its own, derived from some animal or other object. To each medicine prepared according to a prescription must be attached a label, on which is the name of the shop. The so-called homœopathic apothecaries' shops do not exist in Sweden. They are not necessary, inasmuch as homœopathy does not seem likely to be long-lived there, and will soon become an historical curiosity. It is very probable—indeed, I believe it—that in Sweden as in other countries, many hysterical ladies, or *malades imaginaires*, male as well as female, have perhaps derived comfort from the potential homœopathie sugar-grains and interesting conversations with the homœopathic long-suffering physician. But Swedes, in general, do not like this kind of medicine; no foreign, and only one Swedish physician practises homœopathy in Stockholm, and, in the country, I believe not a single one.

Prescriptions and the Price-list of Medicines.—The chemist must put on every prescription the price, which must be according to the rate of the price-list at that time. The Swedish price-list of medicines is revised every year, and the price of medicines is changed according to the market price of the drugs. Medicines for external use ought to have a coloured label, and powerful medicines are to be sealed. The chemist must prepare medicines according to the Swedish Pharmacopœia, unless the physician has *(expressis verbis)* prescribed otherwise. The chemist is forbidden to prepare prescriptions of other than physicians who are allowed to practise in Sweden; and a list of them is every year published by Collegium Medicum. As a physician is not allowed to keep an apothecary's shop, because he has no pharmaceutical diploma, so the chemist is not allowed to practise in medicine; the privilege of that is granted only to such persons as have gone through a complete medical course at any of the Swedish Universities in Upsala or Lund, or at the Medico-Chirurgical Academy of the Royal Caroline Institution in Stockholm. To gain admission into the last-mentioned academy, the student must have passed at some of the universities a philosophical and philological examination. Foreign physicians, unless they can present a diploma as Doctor of Medicine from a well known university, are not allowed to practise medicine in Sweden without a so called colloquium familiare in the Collegium Medicum, or medical course at the Royal Caroline Institution. As the time of the apothecary is not employed in medical practice, and as his competence is sufficient, he can, if he loves science, employ his spare hours with tranquillity in working in that branch of science which he most affectionately embraces. If, in general, a greater scientific activity of the pharmaceutical profession in Sweden is to be desired, we must, however, with pleasure remember that private individuals, distinguished in other countries for original scientific researches, have been met with and are still to be found in Sweden. I will only here mention the most distinguished:—For about a century ago lived in Köping (a very small, and for the greatest part of the world, unknown town in Sweden) an apothecary and chemist, who, with great eagerness, was labouring in chemistry. The good burghers in Köping very likely thought him a clever apothecary, but none of them could foretel that their diligent friend the chemist, *Carl Wilhelm (Charles William) Scheele* in his small insignificant shop, was operating with experiments the result of which should astonish the whole scientific world.

Inspection of the Shops.—The chemists' shops in Sweden must, according to the regulations, be inspected every year. These inspections are performed in Stockholm by two professors or assistant-professors to the Royal Caro-

line Institution, in presence of two members of Collegium Medicum, and in the country of the official physician of the province, together with a magistrate. As the official physician of the province has not time enough for pharmacognosy, the Collegium Medicum has of late proposed to the government a change in inspecting the shops in the country, so that, as in some part of Germany, the whole country will be divided into a certain number of districts, and every district obtain a travelling inspector. Should the inspector find any adulterated or bad medicine it must be immediately destroyed. If an apothecary is three times found to have sold adulterated medicines, he directly loses his privilege, and must give up his shop to another person. It is at the same time a duty and a satisfaction for me to state, that medicines in Sweden are commonly very good, and when adulterated articles are met with are usually such as are imported.

Poisons, or other noxious medicines must not be sold without a sufficient prescription, which ought to be retained by the chemist, and not repeated without a note from the physician. Poisoning is, consequently, very rare in Sweden, and when practised it is commonly by means of white arsenic, which has probably been obtained from a glass manufactory. Secret medicines are forbidden in Sweden, in spite of which charlatans try to sell secretly their all-relieving medicines, but they seem more and more to lose the confidence of the public, and their credit, too, sinks in the same proportion as the reputation of the scientific physician increases.—*Pharm. Jour.*

CORRESPONDENCE.

The following letters require no comment; the facts they state are sufficiently obvious, and this exposure of them will, we hope, lead to a correction of the evils indicated. In this change much hardship must be experienced, but much may be prevented by proper arrangements:—

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—Hoping the Medical Commissioners are subscribers to the Press, I trouble you with a representation of a grievance, as I calculate they are too much engaged at present to be able to pay attention to individual cases; yet many dispensary surgeons may be similarly circumstanced—viz., my half year's salary became due in August last, to meet which there were not sufficient funds in the hands of the treasurer, and from the reply furnished by the guardians to the query—"From what date the present arrangements should come into operation?" I find I shall have worked for three months without any remuneration if, as the guardians desire, it shall date from the first of December.

I consider I have reason to complain of such, and would suggest to the Commissioners a remedy that most likely would apply to very many others—namely, to require the salaries should date from the first of October, when the bill became the law of the country, as our services were continued as usual. Surely, we ought not to suffer on account of the delay of the government appointments. I am unwilling to criticise the acts of various boards of guardians with respect to the remuneration they suggest for their medical officers, anxiously hoping the Commissioners will require some uniform and liberal allowance that will prove satisfactory to the profession generally.

A Dispensary Surgeon.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—Should you deem the subject worthy of notice, I trust you will call the attention of our highly esteemed Medical Commissioner to the following plain statement:—

In a midland union the medical officer had for a considerable time £80 per annum, four years since it was raised to £90; owing to a rival practitioner having got on the board of guardians, it was reduced to £75 this time last year. Since the appointment of Dr. Macdonnell as Medical Commissioner, there was a circular from the Poor-law Commissioners, calling on the medical officers of unions to make such observations and suggestions as they deemed necessary to promote the sanitary condition of the inmates of workhouses. In the conscientious discharge of his duty, the medical officer found it necessary to make some suggestions which might be construed to imply want of due attention on the part of the visiting committee, of which the *rival practitioner is a member*; with the view of gagging the medical officer, and causing him to have due dread of the powers that be, they, on the last board day, recommended a further reduction of his salary to £60, on the plea of economy. The parent house of this union is calculated to contain one thousand three hundred, with an auxiliary capable of accommodating five hundred; they have at present about fourteen hundred inmates divided between the parent house and auxiliary, both of which the medical officer visits daily. In many of the neighbouring workhouses the salary of the medical officer is £100, though none of them are calculated to contain within some hundreds of the house that this gentleman has charge of. Would it not be well to protect medical men from such petty tyranny: if the Commissioners would strike a scale of salaries according to the extent of the houses, this would enable medical officers to discharge their duties more independently. The present uncertain state of their position is calculated very much to impede their efficiency.

I am, Sir, your very obedient,

An Observer.

COUNTY PRESENTMENTS IN SUPPORT OF DISPENSARIES.
TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—In accordance with a recommendation which I recently made through the columns of the *Dublin Evening Post* on the subject of the support of our dispensaries pending the coming into operation of the new "Dispensaries Act," I requested the treasurer of my dispensary to calculate the probable expense of carrying on the institution for two months, from November 1st, and, as heretofore, to collect from the former governors a sum equivalent to one-sixth of their wonted subscriptions. In many instances he got much more, and in no instance was he refused the amount required. This sum I had presented at road sessions, and succeeded in passing, the rate-payers admitting the justice of the claim, and the propriety of presenting for an amount sufficient to pay outstanding debts, and carry on the charity till the *guardians* shall have time to provide for the poor. This I conceive to be strictly in accordance with the intention of the legislature, which, from my construction of clause 10 in the new bill contemplates that all expenses incurred previous to the actual formation of the dispensary district, and appointment of the medical officers, shall be provided for as heretofore.

It may not yet be too late for other dispensary treasurers to make their applications. Secretaries of grand juries will, no doubt, facilitate the object, even though parties may have omitted to apply at the usual period, and at adjourned road sessions the presentment may be made.—Your obedient servant,

Percy Swan Waddy, M.D.,
Dispensary House, Broadway,
November 23rd. county Wexford.

VACCINATION AND SCROFULA.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—In the 15th number of Dr. Copland's Dictionary of Practical Medicine, article—"Scrofula and Tubercles," I have been not a little surprised at the following paragraphs, which will be found in pp. 740, 741:—

"That scrofulous and tubercular affections have increased since the introduction of vaccination is undoubted; and that the dangers from the inoculation of small-pox, under due management and care, in preventing the occurrence of the non-inoculated disease, were actually few, although remarkably exaggerated, are also certain; so that balancing the results from the introduction of the one, and from the suppression of the other, it is very difficult to say that humanity or society has gained anything by these measures."

"Notwithstanding the laudation bestowed upon vaccination, I believe that as the lapse of time allows the fact to be more fully demonstrated, it will be found to be a not unfruitful source of scrofula and tubercle."

Previous to this latter, Dr. Copland says:—"Vaccination may be in many instances the introduction of a poison or

virus, which, slowly and silently, contaminates the frame, without being maturated and thrown out on the surface; whilst small-pox has a very different effect, owing to the free suppuration of the pustules, and the elimination thereby of the morbid material or virus from the system." Yet, sir, Dr. Copland records the fact, that "Lepelletier, Goodlad, and Kortun applied scrofulous pus to the wounds made for vaccination, and also to wounds made without reference to vaccination, but that scrofula was not produced, although the vaccination succeeded when the vaccine lymph was introduced with the scrofulous pus." My experience of nearly thirty years in the profession has led me to a totally different conclusion from that of so high an authority as Dr. Copland, as in many hundred cases of small-pox, both natural and inoculated, I have seen numbers in whom the latent strumous diathesis was rapidly developed, both in scrofulous sores and tubercles, while in vaccinia I never recollect a case where one or other was exhibited. It may be well to call attention to the above deductions of Dr. Copland, and to elicit the opinions of the profession at large on a subject of such vast importance to society as the effect of vaccination being *even likely* to lead to the development of scrofula.—I am, sir, yours,

AN ORIGINAL AND CONSTANT SUBSCRIBER.

P.S.—I would call your attention to page 761 of the same number of Copland, pars. 169-70-71, and the notes thereto, as well worthy a place in the MEDICAL PRESS.

This is an important suggestion. We are not, we hope, about to return to the old controversy raised by the besotted opponents of vaccination at the time of its discovery. We must take our correspondent's hint, and look to it. No more mischievous prejudice could be elicited than that which these foolish remarks of Dr. Copland suggest.

TO SUBSCRIBERS.—We beg of our friends to send us the local papers containing proceedings of Unions respecting the Dispensary Act, or such brief notice as to number, area, and population of districts, with the amount of salary voted. We cannot retain agents in 163 unions.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 3, 1851.

PROCEEDINGS OF GUARDIANS UNDER THE DISPENSARY ACT.

IN our last we confessed our inability, as well as unwillingness, to enter upon this subject, and in refraining from a discussion of it we believe we exercised a sound discretion. From first steps and preliminary operations prospects did not appear encouraging, and there was danger lest a premature exposure of unpropitious proceedings might lead to depression, and consequently to a want of confidence. Since then affairs have in some places assumed a more satisfactory aspect. One of the metropolitan unions, (the South Dublin), has shown a good example in its appreciation of the value of medical services, and elsewhere a proper spirit has been displayed. The Guardians of the South Dublin Union represent a community well circumstanced to give a proper tone to public feeling, as there is amongst them more of the freedom to arrive at just conclusions which competency, if not affluence, engenders, and less of the sordid spirit which belongs to the hard money-getting sections of society or of the parsimonious habits which necessarily attend upon very limited means of livelihood. We scarcely expected much more from the Guardians of the North Dublin Union than they have exhibited; they represent, we believe, pretty faithfully the constituency which elects them, and display the infirmity induced by the wind which blows from one point of the compass. The preliminary proceedings of the Belfast Guardians suggest some inquiries worth entertaining. The subject was ably submitted to their consideration by Dr. MCGEE, who proposed that the six dispensary surgeons, with two apothecaries to compound and dispense medicine now employed for the town, should be continued, but with one station, instead of two, as at present. With respect to salaries, he said "he would advise the Board of Guardians to fix upon such a sum as would be in accordance with a principle which they had already affirmed, not to have any claims made on them for extra labour; but instead of the miserable pittance of £50 a year, now paid to the medical attendants, would name £100 a year." Of the rural districts, he said:—

That there had been a dispensary lately established in Ligoniel; it was an important manufacturing locality, and he would recommend that another district should be that of Ballygomartin, which included some other unimportant townlands. The salary he would attach to that would be £100 a year. There was a difficulty in respect to the district of Whitehouse, and which extended over a very large area. The population, however, was not proportionately large, being only 12,000. He was of opinion that Ballysillan and Carnmoney would ultimately have to be united to Whitehouse in a dispensary district. The salary he should name for the district so united, would be £130, which, considering the extent of area and the expense of horse keep necessary, he conceived to be reasonable. For the Holywood district, he thought the salary should be about the same as that for Whitehouse.

Mr. Senior, poor-law inspector, said that there was one point upon which he did not agree with Dr. McGee—namely, as to the amount of salaries. He himself had a long working experience in England, and he had never heard of such a sum as £1200 a year being set apart for the dispensary expenses of such a union as that of Belfast. They might take Leeds or London, or any of the manufacturing districts in that kingdom, and they would find that such an extravagant figure never had been heard of. In such a place as Nottingham, for instance, where the population was something like that of Belfast, £80 would be looked upon as a liberal allowance, where there were no extra expenses for horse keep. The guardians must be the best judges in regard to Ballymacarrett, and the other proposed districts, but he would suggest a proportional decrease. Perhaps he was going out of the strict line of his duty in making these suggestions; but in every other portion of the proposed arrangements, he quite agreed with Dr. McGee. £1200 a year did seem to him to be a very large sum; and if they took London, or any part of the country, they would find that there was no such high scale of salaries. There was another consideration with respect to the salary of attendants. They were obliged to find a room, or rooms, in which to dispense the medicines, and they might probably set down that item of expenditure at £20. Now, this would no doubt in the end practically amount to an addition by so much to the salary. He was of the same opinion as Dr. McGee, that the salary now fixed should be such as to meet all possible contingencies and vicissitudes, out of which any claims could be made by their medical officers for extra labour done.

Dr. McGee said that it was quite true that in England the sums given were as low as those mentioned by that gentleman; but it was also a fact, that the publications of the country teemed with complaints respecting the system. Was it not a fact that such appointments were put up, and knocked down by Dutch auction, where the person who offered to do the work for the lowest salary was sure to be accepted.

Mr. Senior observed that that was a mistake; that a single instance of such a situation having been given away by tender had not occurred for the last eleven years; in fact, since before he (Mr. S.) came to this country.

Mr. Harrison remarked, that even at the present scale of payments for the medical attendants in Belfast, there were always a large number of properly qualified men found ready to offer themselves as candidates.

Dr. McGee admitted that unfortunately such was the case; but it was also well known that an article might be obtained at almost any price, and he held it to be their duty to get the best men they could. He would put it to Mr. Senior whether there were not payments made to the English gentlemen specially, such as for midwifery cases and for surgical

operations, which had the effect of raising their salaries to a respectable figure.

Mr. Senior replied that such was the case; but that they provided the medicine, which reduced the salary as much as it was supplimented by such charges.

Mr. Harrison inquired whether it might not be right on the part of the board to ascertain the salaries at present received by the medical gentlemen in charge of dispensaries, within the districts they were now forming.

Mr. Senior thought it would be right to ascertain it for the satisfaction of the guardians; but not as any rule of the amount which they were now called upon to fix. He explained his view in this way. In those districts where there were a number of resident gentry, such people would be willing to give a large subscription, with the double view of having a respectable properly qualified medical man in the neighbourhood, and of having the benefit of his advice in case of sickness amongst their servants, or such like. According to this view of the matter, the richer districts, where the smallest number of poor would have to be attended, would offer the largest salaries, whereas those which were very poor, and consequently where the labour would be greatest, would pay least. This was what he thought out to be reversed.

It was here remarked by one of the guardians that there was probably a smaller amount of disease in England than in Ireland.

Mr. Senior said that the contrary would appear to be the case, in so far as a medical officer's practice was concerned. Why, in England, if a labourer's child had only cut his finger, the first thing would be to consult the parish doctor; not so much in regard to the casualty as to establish a claim to other things, to obtain which it required some of the family to be under treatment. The guardians here would understand all about it by-and-by.

Dr. McGee observed that the practice referred to was well known in Belfast, where the principal inducement to apply to the medical attendants had been, in too many cases, to enable the applicant to get "a line" to the ladies—namely, to the Destitute Sick Society, a very worthy institution in town. He would also say, that a gentleman accepting a situation under the new act, was placing himself in a different position from any heretofore known. If he were dismissed, he would be held disqualified from being ever appointed to a situation under the poor-law authorities again; and some consideration should be allowed for the responsibility so incurred. Neither was the fact of their now accepting £50 a year any argument against their claims for a liberal salary; for, upon the same grounds, they would only have to go back four or five years to a period when they received nothing at all, but gave all their services gratuitously.

Another conversation took place about the amount of salary, as ranging between £50, the lowest mentioned, and £100, that proposed as remuneration for the Belfast medical attendants; and it was suggested that £75 might be named for the latter.

Mr. Lepper entered into a calculation, embracing the sum now proposed to be given to the Belfast attendants and apothecary, and the sum they at present receive. The whole cost at present is £430; it had been proposed to give them £800, making a difference of £370. Against this, they had the extension over Townparks, Edenderry, and Lower Malone, and the vaccination practice, which cost the union at present £80. He believed that the fixing of salaries at £75 would bring the matter down to a fair point.

Mr. Watson said the inspector might not be at all uneasy in regard to the sum of £100 per annum for each of the medical attendants in Belfast being ultimately carried, for there was no such idea entertained by the guardians.

A good deal of further conversation took place. In the course of it, it transpired that the present holders of situations as dispensary doctors are entitled to a preference in the new appointments. Finally the question was put to the vote—namely, whether or not Dr. McGee's suggestions should be embodied in a circular convening the guardians for a future day. There voted nine for it, and three against it.

Mr. Senior inquired whether the board was of opinion that he could be of any service to them on the occasion.

Several members answered affirmatively; and

Dr. McGee said that he was sure to meet in Mr. Senior very strong opposition as regards the amount of salary to be paid the medical attendants in Belfast; but there was no member of that board who would be more delighted to have his assistance on that occasion, or any other, than himself.

We give this discussion in detail, because it raises many of the points which must necessarily become the subject of discussion, and because it "drew out" a poor-law inspector respecting them. It is scarcely necessary to say that we do not agree with Mr. Senior, except in one point, that "perhaps he was going out of the strict line of his duty in making these suggestions;" in this we cordially agree. He had no business whatever to interfere in the matter, and was only making an early display of the interference to be expected from him and his brother inspectors in a department with which they are to have no concern. If conflicting opinions and actions are tolerated between the general and medical inspectors, we shall have a fine mess of it: some other work must be cut out for supernumeraries than that assigned to the medical inspectors. To Mr. Senior's argument the reply is a short one: Ireland is not England. The threatened resistance to Dr. McGee's proposals by some of the Guardians was to be expected. The "Mr. Harrison" who offered a characteristic form of opposition to them, is, "we guess," the brother of our Dublin medical friend, from whose tender mercies as Commissioner our profession has had so narrow an escape. In Waterford the matter has been taken in hand by Dr. Mackesey (who, fortunately, is on the Board there), and it is to be hoped that with his assistance proper arrangements will be adopted. Here are the proceedings in that union:—

The subject of the salaries as fixed by the board on Monday last, having been introduced by Dr. Mackesey,

The Chairman said if the salaries are to be increased at all it should be in the rural districts. Waterford ought to be reduced. He considered £80 too small in the rural districts. The salary in Waterford is large (£100).

Dr. Mackesey said, I am much gratified, Mr. Chairman, in having an opportunity to give my opinion of the total inadequacy of the salaries voted by the board on Monday last for the medical officers to be appointed to the dispensary districts of this union. I also concur with you that when a dispensary district includes a number of resident gentry able to employ and remunerate a medical practitioner, that the salary of the medical officer of that district may be on a reduced scale, unless, as in the present instance of the Waterford dispensary district, the duties are so severe, that if the surgeon fairly attends to those duties it will be totally impossible for him to engage in private practice. On Monday last I was, on attending the board, under the impression, that we should only divide the union into dispensary districts, and that the subject of the salaries for the medical officers would be taken into consideration on some future day. I was therefore unable to enter fully on the subject, and I shall now beg leave to give notice that on this day fortnight I will move that the resolution adopted on Monday, the 17th instant, fixing the salaries of medical officers, be rescinded, as I consider those salaries to be inadequate, and that instead thereof such medical officers be paid each 5s. per diem, with such allowance for a horse as may be considered necessary by the board. This will be a much smaller salary than is generally paid to the surgeons of dispensaries in this union at present. Anxious, however, for economy, and to meet the views of the guardians, I shall not propose a larger sum; and I am satisfied you should not, in justice to those gentlemen, offer a smaller. I shall, for example, mention the case of Dr. Cullinan, of Kilmacow, who will succeed to the Ullid district. He has been the attendant of that dispensary for nearly thirty years, during which long period, I can say from intimate acquaintance with that locality, both as a physician and a landed proprietor, that by his professional talents, his humane attention, his great industry, he has secured the good opinion, the respect, and esteem of every man in the county, whose opinion is worth having. I would ask the board is a man like this, now advancing in life, after thirty years active duty in the service of the public, to have his duties greatly increased and his salary cut down one-third—for his former salary was one hundred guineas per annum, and his vaccination contracts amounted to £15 per annum, making his public income £120, which you now, by your re-

solution of Monday, reduced to £80; and he is now obliged to vaccinate as part of his dispensary duty. I feel, deeply feel, that I do not act with justice, in only proposing to you as the salary of this old, valued, and efficient officer, the small sum of 5s. per diem, £92 5s. per annum. Before I conclude, I must point out that this is no new impost upon the county. This is no new taxation. Until the passing last session of the Medical Charities Act for Ireland the dispensaries were supported by private subscriptions and grand jury presentments; and I expect, by the close attention of this board, the taxation under the poor-law will be less than the former taxation under the grand jury, and that the relief will be more efficient. But I beg to point out to you that in the treatment of the sick parsimony is not economy, and I trust on this subject being again brought before you that you will allocate that salary to the medical officers that the responsibility of their situation and the severe duties imposed on them require, and that you will take into consideration in allocating those salaries the state of the country, which, from the ruined condition of the gentry and the better class of farmers, and from the extensive emigration now going forward, leaves a country practitioner but little chance of private practice. A short discussion ensued, during which some of the guardians thought the former resolution should not be altered, whilst the majority were of opinion that the amount of salary fixed for the medical officers of the rural districts was quite inadequate to the duties each will have to perform; besides it would be impossible for any medical practitioner to perform with satisfaction to himself or justice to the public the onerous duties that will devolve on him without keeping a horse. Every guardian present admitted this fact.

At Roscrea, the *Leinster Express* states:—

The division of the union into dispensary districts, under the provisions of the Medical Charities Act was yesterday (Friday) discussed. We understand that the following recommendations were offered:—That the union be formed into three dispensary districts. That a medical officer shall reside at Roscrea, with offices at Aghancon and Kyle, each of which he will attend on two days in each week. That a medical officer shall reside at Shinrone, with an office at Moneygall, which he shall attend on three days in each week. That a medical officer shall reside near Bourney church, and that he shall attend on three days in each week at an office at Barnane. That the salary of each medical officer be £80 per annum. Whether the above arrangements were decided on, we had not heard at the time of going to press.

We entertain some doubts as to the possibility of carrying out such an arrangement as this, but unacquainted with the locality, we will not venture to say that something of the kind may not be effected. We do not, at first sight of it, much like this plan of establishing "offices" or "stations" to be visited periodically by the surgeon; it looks very like one of the old abuses which this act was passed to correct, non residence and plurality of appointments. It is not a flying visit to dole out physic the sick poor of this country want, but a resident surgeon, who will become, in process of time, intimately acquainted with their condition and wants, and an efficient agent to carry out the views of the Commissioners for their welfare as to sanatory arrangements. We hope to see this act carried into effect in a statesmanlike and comprehensive way; embracing objects of much more importance than mere routine "doctoring."

In many unions we find the natural desire to escape from the payment of poor-rates influencing the Guardians in their decisions as to the expenditure for the relief of the sick poor. In the Rathdown Union, which extends to the bounds of the city of Dublin, we understand that this preference of the charity which begins at home has prevailed; and even in Limerick and Cork domestic privations become manifest, in the public display of an economical spirit. In the Athlone Union £75 per annum has been assigned for districts eight miles square; one of them containing a population of 20,000. At Ballina, £60 a year is granted for a district of fourteen miles square; and in many other places it is the same. In some places we find the Guardians losing temper at the prospect of an additional penny in the pound. A Lord Castlemaine, in Athlone, "does not care a farthing about the doctors, he considers the ratepayers first;" and another Lord, not a hundred miles from Dublin, is in the same temper. The upshot of all this will probably be a settlement of the question by the Commissioners. It is evident that some principle must be adopted, and made the basis of a rule for general application.

THE APOTHECARY AS HE SHOULD BE.

We bespeak the attention of our readers to the article entitled "Pharmacy in Sweden," page 361. It is a melancholy reflection that these countries which boast so much of the superiority of their institutions should be so excelled in a matter of this kind by a people so inferior in wealth and power. The state of pharmacy in the united kingdom, so far as apothecaries are concerned, is a reproach to the national character. In England, if it were not for the chemists and druggists, no physician or surgeon could practise with safety or effect; and in Ireland the Apothecaries' Company has become a nuisance, by its perversion of the law, its obstruction of pharmaceutical education, and its incessant impudent attacks on the surgical profession. The audacious proceedings of certain apothecaries in Dublin, in relation to the private practice of those who do not belong to the knot which plays into their hands, has become so intolerable that it can no longer be borne. These doings, however, prove the truth of the saying "that out of evil cometh good." They have led to the establishment in this city, and probably elsewhere, of admirable pharmaceutical establishments conducted by true apothecaries who devote themselves to their legitimate business, to the great comfort and advantage both of practitioners and patients.

MEDICAL PLURALITIES.

We have had several inquiries as to the legality of one surgeon holding two professional offices; such, for example, as those of attendant to a workhouse and to a dispensary We see nothing in the poor-law or dispensary acts to forbid it, but it is a dangerous experiment. As time wears on, duties may become lighter, and the workhouse surgeon may some day or another find himself in the care of two institutions with one salary.

SOUTH DUBLIN UNION.

DISPENSARY DISTRICTS.

A meeting of the guardians of this union was held on the 28th ult., pursuant to notice in the board-room of the workhouse, James's-street, for the purpose of taking into consideration the letter of the Poor-law Commissioners relative to dispensary districts and other matters immediately connected therewith.

The letter of the Commissioners having been read,

The Chairman said that the first thing to be done was to divide the union into dispensary districts.

It was then moved and seconded, and finally agreed to, that the south city electoral division should form one dispensary district.

After a lengthened discussion, the rural divisions were formed into the following dispensary districts:—Clondalkin, Palmerstown, Rathfarnham and Whitechurch, Donnybrook, Rathmines, and Tallaght.

Mr. Bonsall moved that the south city electoral division should be subdivided into four dispensary districts.

The motion having been seconded by Mr. Dowling, was put from the chair and passed.

The Chairman said that the next point on which the Commissioners requested information was as to how many medical officers should be appointed to such dispensary.

After some discussion it was finally agreed that each of the city dispensary districts should have two medical men and an apothecary, and that each dispensary district in the rural divisions should have one medical officer.

The Chairman said that the next question was as to the salary.

Mr. Carolan moved that each medical man in the city districts should receive £100 per annum.

Mr. Price seconded the motion.

Mr. Evans opposed it. He considered the work could be done quite as efficiently at a salary of £80. He would accordingly move as an amendment that each medical man should receive but £80 yearly.

The amendment was seconded by Mr. Parker.

The motion was then put from the chair, and the numbers on both sides were nearly equal.

Mr. Evans called for a division.

This was accordingly done, with the following result ;—The numbers were—For the original motion, 10 ; against it 8. The amendment was therefore lost.

It was then decided that each of the medical officers in the rural dispensary districts should also receive £100 per annum.

The following resolution was moved by Mr. Bonsall and seconded by Mr. Price, and having been put from the chair was unanimously agreed to : —

" That this board are of opinion that the medical officers to be appointed to the several districts of this union should reside in the most central portion of their respective districts."

Mr. Crawford said that it would be as well that the board should specify in what portion of the respective districts the dispensaries should be situated.

The board then proceeded to the consideration of the subject, and it was finally agreed that dispensaries of the respective districts should be situated in the following places :

For Clondalkin, in Clondalkin ; for Palmerstown, in Palmerstown ; for Donnybrook, in Donnybrook, near Ball's-bridge ; for Rathfarnham, in Rathfarnham and Crumlin ; and Tallaght, in Tallaght.

It was decided that the above arrangements should (if approved of by the Commissioners) come into operation on the 2nd January. 1852.

The Clerk was directed to forward the above proceedings for the inspection of the Commissioners, and the guardians then separated.

NORTH DUBLIN UNION.

A COMMUNICATION from the Commissioners was then read by the clerk. It referred to the proceedings of the previous board day, and requested that a more detailed account of the views of the guardians should be sent to them. It especially called for a statement of the number of dispensaries which the board would recommend ; also for a reconsideration of the extent of the Clontarf and Howth electoral divisions, in which there were two dispensary officers, and to state the reasons which induced the guardians to consider that these divisions should have one dispensary officer instead of two as heretofore. They also requested to be informed what salary the guardians would recommend to be given to the medical officers, and also the time at which they would suggest that the proposed alterations should come into operation.

The Chairman said that the way to dispose of the letter was to take it in portions. The first question to which the Commissioners required an answer was, how many dispensaries did the board think requisite for the north city electoral division?

Mr. Long proposed that three dispensaries should be nominated, and that two medical officers should be attached to each dispensary.

Dr. Brady was of opinion that six dispensaries, with one medical officer to each, would be a far more effective plan.

Mr. Long said that by having two medical men to each dispensary one of them could always be on the spot, which would not be the case if but one were appointed. Besides by having but three dispensaries, the ratepayers would only have to pay one-half the rents as well as one-half the expense of the sets of medicine. He would propose the following resolution :—

" That we consider three dispensaries sufficient for the north city electoral division, and that two medical officers be appointed to each, the arrangements of visitation and dispensary relief to be settled by the managing committee, subject to the rules and regulations of the Commissioners, so as to have constant and immediate attention to the wants of the poor."

The resolution having been seconded by Mr. Studdart, was put from the chair and carried.

The Chairman then said that the next question which arose was with reference to the district comprising Howth and Clontarf.

Mr. Long entered at some length into details respecting the above division, and concluded by moving the following resolution, which was seconded by Mr. Law, and carried:—

" That the guardians in forming dispensary districts in the rural divisions considered both the area and population, and on reference thereto find that the district comprising Howth and Clontarf is the lowest both in population and area, and therefore see no reason for altering their original opinion."

The Chairman next called the attention of the board to the salaries which should be given to the medical officers.

After some discussion the following motion was proposed by Mr. Long .—

" That we consider £100 a year fair remuneration for each of the medical officers in the rural dispensary districts, provided that the districts as recommended be adopted ; and that £75 be also a just payment to each medical officer in the north city electoral division, subject also to the approval of the Commissioners, that six medical men and three dispensaries be the best arrangement to be adopted."

Mr. Studdart seconded the motion.

Mr. Hyndman moved, as an amendment, that the payment for each of the medical men in the city dispensary districts be £60.

A division having being called for, the amendment was carried by a majority of three, the numbers being eight to five.

Mr. Long then moved, as an amendment on the remaining portion of the motion, that the payment in the rural dispensary districts to the medical officer be fixed at £80 per annum.

The motion having been put, the amendment was carried by a majority.

At the suggestion of Mr. Long, the date at which the proposed alterations should come into operation was fixed at January 1, 1852.

A CHEAP REMEDY FOR ALL DISEASES.

GERMANY, the modern hot-bed of quackery, from whence hydropathy, mesmerism, and homœopathy, with various other fanciful fallacies, have all proceeded, has recently become the birth-place of a new *pathy*, that seems to be already advocated by prophets and proselytes. We now allude to the newest theory in the healing art, invented by our Teutonic neighbours, which a Herr Maher, of Naumberg, has just launched amongst his credulous countrymen. According to the dogmas of this novel sect, patients anxious to recover from disease, or those who, being well, desire to live even unto a patriarchal age, must resume the primitive mode of life pursued by man's antediluvian ancestors. In fact, neophytes, and all labouring under any malady, ought henceforward to walk bare-footed ; to adopt bread-and-water diet ; whilst allowing their hair and beard to grow luxuriantly, as Nature intended. The great apostle is most ardent in favour of his present doctrines, and preaches the necessity of being regenerated after the manner of our original forefathers, as well on account of the essential curative advantages thus obtained as many important moral benefits. Already considerable excitement prevails at Naumberg, where wits and unbelievers nevertheless assert that the originator of the system does not rigidly act according to his own principles, as beer and tobacco—so dear to all true Germans—are sometimes taken as " solatia," although rigidly prescribed in the authorized pharmacopœia. Expecting " primopathy" will soon make bold attempts on John Bull's capacious pockets, we would, in the interim, seriously recommend mesmerists, homœopathists, *et hoc genus omne*, to look well after their fading laurels, since, doubtless, so soon as this last-invented German theory obtains a footing in the British dominions, some portion of that floating credulity incident to particular classes in this country, as elsewhere, and which always runs after every novelty, however ridiculous, will assuredly desert their former colours, in order to range themselves under the new standard.—*Lancet.*

INOCULATION, HOW FAR USEFUL IN FORMING A DIFFERENTIAL DIAGNOSIS IN SYPHILITIC DISEASES.

By JOHN C. EGAN, M.D., F.R.C.S., M.R.I.A.,
Formerly Surgeon to the Westmorland Lock Hospital.

MR. PRESIDENT and GENTLEMEN,—The medical historian to whose lot it shall fall to record the discoveries of peculiar interest which have for the last few years emblazoned the page upon which the improvements of our art are stereotyped, shall pause with feelings of dignified pleasure, when he shall arrive at that department in nosology, which has for its aim the elucidation of disease by a careful study of the symptoms which present themselves to the notice of the practitioner. And as he passes in review before him the illustrious names of those who, by the appliances of modern invention, have contributed in no small degree to simplify the nature and divest of their obscurity the characters of those maladies which were formerly but little understood, he shall likewise, doubtless, dwell with more than ordinary emphasis on the improved and scientific line of treatment which the art of correct diagnosis has ensured. On the present occasion, I purpose making a few observations on a subject which has as yet attracted but little attention in this country, but which has in the hands of our continental brethren proved of considerable importance to those engaged in the study of special diseases—I allude to inoculation as employed in testing the character of syphilitic affections, with a view to establishing a differential diagnosis between them.

Prior to the time of Hunter, inoculation had been practised in investigating the nature of venereal diseases, but as the experiments instituted by that distinguished surgeon are among the first of which we have a detailed description, I shall commence by giving an abstract of them, as contained in his work. Two punctures were made on the penis with a lancet dipped in venereal matter from a gonorrhœa, one puncture on the glans, the other on the prepuce. The immediate effect of the operation was an itching in the inoculated part, inflammation succeeded, and a "speck" formed where the puncture had been made; this was touched with caustic, and dressed with calomel ointment. The slough having come away, it was again cauterised, and the operation was repeated at each appearance of the speck with similar results. Four months after the healing of the ulcer on the prepuce, the chancre broke out again, and healed without any application; that on the glans, however, remained perfect. During this time a swelling of the glands of the right groin took place, which was resolved by mercurial frictions. Two months after the disappearance of the bubo, pain was experienced in swallowing, and upon examination a small ulcer was discovered in one of the tonsils, for the cure of which mercury was resorted to. About three months after, "copper-coloured blotches" broke out on the skin, and the ulcer in the tonsil reappeared, for which mercury was again exhibited, but not in sufficient quantity to arrest the progress of the disease: a relapse again took place, for which mercury was freely administered, and after a period *of three years* a cure was permanently effected.

This experiment of Hunter's is now almost universally acknowledged to be as inconclusive, as it is imperfect. The spontaneous healing of the chancres, an effect which, according to the opinions of that day, could not be brought about without the aid of mercury; the occurrence of bubo, which, in all probability, was merely consequent on the irritation produced by the process of inoculation; the ulcers of the throat, the nature of which is undefined; the supervention of copper-coloured blotches; symptoms vaguely described in an individual under treatment, moreover, for three years; and the probability of renewed infection during that period,—all these circumstances taken together must afford but slender proofs of the identity of the matter of gonorrhœa and chancre, or of the nature of constitutional symptoms likely to follow such an experiment. The first conclusive experiments, and which have been fully substantiated by all subsequent manipulators are those recorded by Benjamin Bell.

Two young students having obtained gonorrhœal matter from patients labouring under that disease, placed it between the prepuce and glans, and allowed it to remain in that situation for the space of twenty-four hours. In one, a considerable degree of inflammation, followed by a discharge of fœtid matter from the urethra, was the result, but these symptoms of "bastard gonorrhœa" shortly disappeared under the use of bread cataplasms with a solution of acetate of lead, laxatives, and a severe regimen. No chancres followed. In the other, inflammation did not run to such a height, but the matter having made its way into the urethra, he was attacked on the second day by a discharge from that passage, attended with a considerable degree of pain, and which continued for a year. This gentleman having suffered so severely instituted no further experiments. His fellow-student, however, persevered, and shortly after the subsidence of inflammatory symptoms, consequent on the former inoculation, introduced gonorrhœal matter into the substance of the glans, which he repeated on three several occasions, but without being able to produce chancres. Finally, he inserted on the point of a probe matter taken from a chancre, which he introduced to the depth of three or four lines into the urethra: no symptoms of gonorrhœa appeared, but in five or six days a chancre was perceptible on the spot where he had applied the matter. To this succeeded a bubo, which suppurated, ulcers of the throat followed, and he was unable to leave his room for a month; he was eventually cured by the administration of mercury. In his remarks upon these interesting results, Mr. Bell observes—"I was by these experiments enabled to produce the most decisive proofs that could be desired of the difference between the matter of gonorrhœa and syphilis, and to show neither chancres, nor other general symptoms, can be produced by the matter of gonorrhœa, whilst that of syphilis, even to the secreting surface of the urethra, produces chancres, which afterwards introduce the infection into the system."*

But it is principally to the indefatigable exertions and laborious research of M. Ricord, that we are indebted for an accurate detail of the results produced by inoculation, he having devoted several years to the investigation of that particular subject in the wards of the Hôpital des Vénériens at Paris. In his valuable treatise,† he gives a detail of numerous cases in which he experimented with the matter of simple gonorrhœa, virulent gonorrhœa, chancre, bubo, secondary and tertiary symptoms. By these experiments he has proved that the matter of mild gonorrhœa is incapable of producing ulceration, except when it is thin and serous—a condition in which it is only to be found the few first days of infection; a stage of the disease seldom encountered in hospital practice, and therefore not likely to form materials for accurate deductions. In virulent gonorrhœa, which he states always depends upon a concealed chancre in the urethra, he has succeeded in producing the characteristic pustule by inoculation—a form of disease likely to be followed by mild secondary symptoms. He has further demonstrated that chancres in their primitive or ulcerative stage are capable of producing similar ulcers by inoculation; but when the period of reparation arrives, and they begin to take on the healing process, they are no longer recognized by this diagnostic peculiarity. From his experiments on the matter of buboes, M. Ricord has concluded that those sympathetic enlargements of the inguinal glands, the result of gonorrhœa, produce upon inoculation negative results, while those consequent on chancre afford the characteristic pustule. In no instance has he been able to produce any effect by the inoculation of the secondary or tertiary forms of syphilis. Immediately upon my appointment to the Westmorland Lock Hospital in April 1843, I commenced a repetition of those experiments detailed by M. Ricord. A numerous class of patients labouring under gonorrhœa afforded me ample scope of testing the accuracy of the results as set forward by that eminent continental surgeon. In those cases I was unable, after repeated trials, to obtain any result by inoculation of the gonorrhœal matter, which I inserted by means of a lancet, in the upper part of the thigh of the affected patient. I had no opportunity of practising inoculation on individuals who had contracted ulcers in the urethra, and cannot therefore say from experience what might have been the result of such a proceeding;* but many cases presented where the discharge was accompanied by abrasions or superficial ulceration of the vaginal mucous membrane, and which was followed by a mild form of secondaries (generally a papular eruption over the body), although incapable of inoculation. In alluding to this condition of parts, M. Ricord observes—"It is now well known, and proved by pathological anatomy, that, as the speculum shows us every day, gonorrhœa is often accompanied, or followed by erosions, or more or less extensive destructions of the mucous membranes; but the ulcerated form of gonorrhœa, if I may thus express myself, does not render it more capable of being inoculated than that which is not, the gonorrhœal ulcers being essentially distinct from chancre." As to whether these abrasions, or simple excoriations of the mucous membrane, which existed in many cases, coetaneously with the gonorrhœal discharge, were caused by the latter disease in its inflammatory or virulent stage, or by a specific virus, are questions of by no means easy solution, but certain it was that not a few of them were succeeded by constitutional symptoms, where no other form of lesion could be discovered on the most minute and careful investigation. To this latter statement it may be urged, that the specific sores may have had full time to heal from the first accession of the disease till the period when the patients were admitted into hospital; and although the force of the objection cannot be denied, yet I conceive that the fact furnishes at least presumptive evidence that the matter of gonorrhœa in its incipient state (a condition in which I had never an opportunity of testing it) is capable of producing this excoriation, which may be followed by a mild form of secondary symptoms: and this view of the case would appear not altogether to rest on mere assumption, being borne out by the observations and experiments of Mr. Evans. As regards, however, the views put forward by that gentleman, and which are to be found in his treatise on Ulcerations of the Genital Organs, I think it but fair to state that they were founded on the very imperfect examination of females, which we are enabled to make, without the aid of the speculum; for although venereal ulcerations are but very rarely met with on the neck or mouth of the womb, yet these sores are occasionally seated at a distance within the vagina, where it would be impossible to detect their existence without the assistance of an instrument such as that alluded to. Mr. Evans made, I have no doubt, as careful an examination as could be expected under the circumstances, and his diagnosis was assuredly in many instances correct, but it must nevertheless be evident from such inspections he was not justified in confidently drawing the deductions which he has laid down, more especially when he concludes that particular part of his essay in the following words: "Whether or not, in some cases, ulceration exists beyond the reach of the eye, can only be decided by examination after death. I must acknowledge no good reason presents itself to point out why it should not; but as we have no proof that venereal ulcers do form so far within the vagina as to be beyond discovery, I am in no way disposed to argue upon the supposition that they do, particularly as this is one of the many matters of fact that cannot be demonstrated by reasoning."† The apparent anomaly of a woman infected

* Hernandez, the successful competitor for the prize awarded by the Medical Society of Besancon, has likewise satisfactorily proved by a series of experiments performed on convicts during his attendance on an hospital for galley-slaves, that the virus of gonorrhœa, and that of chancre, are different and distinct.

† Traité Pratique des Maladies Vénériennes, Paris, 1838.

* M. Mairion tested eighty-five cases of gonorrhœa; of these, four yielded a specific pustule from inoculation; in those latter cases, chancres were discoverable in the urethra.

† Remarks on Ulceration of the Genital Organs, p. 78.

with gonorrhœa alone, being able to communicate venereal ulcers to one man, and gonorrhœa to another, is now, I believe, no longer put forward by the advocates of the identity of the two poisons, as in every institution an opportunity is afforded of demonstrating by means of the speculum that chancres may exist deep in the vagina, where no form of ulceration will be perceptible externally, and where the only symptom of disease is that which will give rise to the impression on the mind of the medical attendant, that the patient is labouring under the effects produced by a gonorrhœal discharge only. If the merits of the speculum vaginæ were only appreciable, as far as assisting to explode this paradoxical idea, its use as a valuable boon to our means of diagnosis must be hailed with pleasure by all engaged in the study of syphilitic diseases.

That a considerable proportion, however, of the cases of secondary symptoms which have been supposed to result from simple gonorrhœa, owed their existence to a concealed urethral chancre, can now be no longer doubted; such instances are alluded to by Hunter, and have been clearly pointed out by M. Ricord, Mr. Parker, and others, and to no other explanation can we refer in proof of the success which followed the mercurial treatment, as practised by the late Dr. Wallace of this city in cases where he was unaware of this complication. My attention was next directed to the inoculation of the matter of buboes, two classes of which, the sympathetic, usually consequent on gonorrhœal inflammation, and those produced by the absorption of the syphilitic virus, presented themselves to my notice. As regards the experiments which I had an opportunity of instituting upon the former, which were characterized for the most part by tumefaction of the deep-seated glands, I was unable after repeated trials to elicit any effect beyond slight irritation of the cuticular surface, results so far coincident with the experiments of M. Ricord; but I have been convinced from frequent observation, that even here a mild form of constitutional symptoms, as a papular eruption, an erythematous redness of the fauces, has often resulted on this affection.

In the latter, the virulent bubo of M. Ricord, I have succeeded in several instances in producing the characteristic pustule by inoculation; these enlargements of the inguinal glands were distinguishable from the former by being generally confined to the superficial ganglions. I must, however, confess, that although my experiments were performed in strict accordance with the rules laid down in those cases for the operator by M. Ricord, I was not unfrequently disappointed at finding that inoculation did not give rise to the pustule which makes its appearance after the introduction of the venereal virus. While, therefore, I admit that this test when applied to enlargement of the inguinal glands, will, in many cases, serve to distinguish the nature of the cause that produced this secondary effect, I cannot concur in the conclusion at which M. Ricord arrives when he states, that inoculation in bubonic enlargements must be relied upon as forming an unexceptionable and pathognomonic sign. Moreover, I am inclined to think that, even from his own experiments, this deduction is of too sweeping a nature; as even in cases where buboes resulted on chancre, he was not always successful in producing positive results—these effects not being produced at all in some instances, and in others not till after a repetition of the experiment. It is true that in these unsuccessful attempts, M. Ricord has endeavoured to point out the causes of failure; the pus being sometimes taken from a gland too near the surface, at other times from a mixture of that contained in a superficial and deep ganglion, and occasionally from the pus contained in the surrounding cellular tissue. Further, he observes, that in order to produce a specific pus, it is not only necessary that the bubo shall have been consequent on chancre, but that the virus shall have been transmitted to the gland by the process of absorption, and not by any sympathetic irritation. But admitting that to one or other of these circumstances, want of success can be always attributable—points which may perhaps be satisfactorily made out in the mind of an expert and experienced manipulator—it must nevertheless be sufficiently obvious that, to an operator of less practical knowledge of the cautions required and the difficulties to be avoided, conflicting statements and contradictory results must frequently ensue, which in a medico-legal point of view might be attended with unhappy consequences. Thus, Dr. Wallace informs us, that although he inoculated some hundred times with the matter discharged from buboes, he only succeeded on three occasions in producing any specific effect. On these occasions, the ulcers that resulted, presented during their entire course the characters of the primary syphilitic ulcer. On the other hand, Mr. Hamilton, whose experiments were performed at the Richmond Hospital, in this city, states that the facts which he has observed in his own trials of inoculation, bear out in every particular the truth of M. Ricord's researches, and that this is the surest test in determining the virulent or non-virulent character of buboes. There is another form of bubo alluded to by M. Ricord, of which he admits the existence, although he states it is of rare occurrence: this he denominates the primary non-consecutive bubo *(bubo d'emblée)*. The existence of this species of inguinal enlargement was likewise attested by Fallopius, Astruc, Swediaur, Bertrandi, and Gibert; and is said to present itself after impure sexual intercourse, without the intervention of any antecedent form of disease. As I have never met with a decided example of this affection, the existence of which my experience would lead me to deny, I shall transcribe from M. Ricord's work the passage which bears upon its history:—"If (he says) the patients be closely and minutely questioned, one will soon be convinced that the reputed primary buboes are very rare; for most frequently, in those which were supposed to be such, we find the cause so evident that we are surprised that the patients themselves did not perceive it. Thus, patients who have only become aware of their disease by the development of a more or less painful tumour at the anus, will only speak to you of this tumour, which they only perceived the day previous, or even that day. If you interrogate them, they state the last coition to have been a fortnight, a month, or more, previous; if they be then examined, a chancre will be found, often pretty extensive, upon the penis, prepuce, or some neighbouring part. Yet, after an unclean connexion, the engorgement of the ganglions, situate near the sexual organs, become, though rarely, primarily diseased. There are some circumstances in which it is impossible to find any suspicious antecedent or concomitant, and we are then obliged to admit the existence of the primary non-consecutive bubo *(bubo d'emblée)*. If these engorgements be attentively examined, without being led into error by those which may resemble them, it will be found that they generally make their appearance in the deeper ganglions, and not unfrequently even in those of the fossa iliaca, or at least the subaponeurotic of the thigh; that their progress is often chronic; that they are a long time indolent, and have little tendency to suppuration; but what is most remarkable is, that, when they suppurate, the pus they furnish does not inoculate. Hitherto I have never found a bubo, with all the rational signs of a non-consecutive bubo *(d'emblée)*, which furnished an inoculable pus. If to this important observation be added, that, after very careful researches, I have never found that a strictly speaking non-consecutive bubo has been followed by symptoms of general syphilis, the importance of inoculation in this case will be apparent."

Before proceeding to the description of the primary syphilitic sores, whose characters I had an opportunity of testing by the process of inoculation, it may be well to give an outline of the appearances which inoculation of the venereal virus produces in and around the part where the specific matter is inserted, and which will explain the meaning of the term "characteristic pustule." It will be likewise necessary to premise, that, for the purposes of inoculation, it is essential to bear in mind the transition through which a venereal ulcer passes previous to its cicatrization or complete disappearance, during which period

two distinct stages are recognizable; the first being that of ulceration, which may be prolonged to an indefinite space of time, and in which the sore furnishes a specific pus; the second, that of reparation, in which the venereal virus is no longer demonstrable by inoculation.

If matter be taken from a chancre during its first or ulcerative stage, it will produce the following effects:—Inflammation will be at the termination of the first day more or less apparent at the point where the skin was punctured; on the second day tumefaction of the adjacent parts will be added; on the third, an areola of a rose-coloured tint will present itself; on the fourth, a vesicle, which will have the effect of raising the cuticle, and on whose summit a dark speck is generally observable, will be perceptible; on the fifth, a depression is observed on the apex of the vesicle, and its contents are changed from a transparent to an opaque purulent matter; on the sixth, induration in the surrounding and deep-seated cellular tissue ensues, the pustule decreases, and on the succeeding days a number of concentric crusts are thrown around the pustule, and present a conical appearance. On the disappearance of the crusts, an ulcer with an indurated base, undermined edges, with a surface of a bright red colour, smeared over with a thick tenacious matter, is disclosed to view: this ulcer is bounded by a dark livid and elevated margin. Such is the progress of the syphilitic virus, and such the effects generally occasioned when matter taken from a specific ulcer is inoculated beneath the epidermis.

But although this would be conclusive evidence of the specific nature of the ulcer from which the pus had been taken, we must not be disappointed if we should fail to produce this positive result by inoculation. During the course of my experiments, I have been not unfrequently foiled in obtaining this decisive proof of the virulent character of the ulcer; although from the appearance of the primary sore, and the subsequent effects of the poison upon the constitution, conclusive evidence was afforded of the contaminating influence of the disease. In some of the cases to which I allude, the only effect produced was slight inflammation, which, in the course of a few days, subsided; in others, the inflammation ran to a higher pitch, and terminated in an unhealthy phlegmonous abscess; while in a third, no visible effect was at all discernible. These remarks more particularly apply to the first class of primary ulcer, which I shall have occasion hereafter more fully to describe, characterized more by negative than positive symptoms—namely, the absence of induration or excavation to any considerable extent, and which constitute by far the most extensive class which are met with in practice. It may be argued that the cause of failure in these cases was owing to want of sufficient attention on the part of the operator in neglecting to take the matter at a time favourable to the propagation of the venereal virus—viz., in the ulcerative stage of the sore, previous to the setting up of the reparative or healing process; or that the pus inoculated, although taken at the proper period, was inserted too deeply beneath the epidermis, and by coming in contact with the cellular membrane, gave rise to phlegmonous inflammation terminating in abscess. Or, lastly, that these instances in which inoculation did not produce the characteristic pustule were merely simple non-specific ulcers.

To these objections I can safely reply, that from the care and caution with which these experiments were instituted, no such casualties could have occurred. However, even in this form of primary syphilis, sufficient proof was available, in a succession of secondary affections, to demonstrate the virulent specific or poisonous nature of the superficial non-indurated sore; but as it is in inoculation with the matter of cow-pock, so also does it occur in the insertion of the syphilitic virus that failure, owing to causes over which we have no control, as the resistance of surfaces, even in conditions apparently favourable to the reception of the virus, must occasionally prevent the development of the symptoms consequent upon the introduction of the poison.

That this test was applied to a few simple non-specific ulcers, I am willing to concede; but in these cases it was almost evident to any person acquainted with the appearances of venereal sores, previous to inoculation, that no other result could have been anticipated. But it is more especially in reference to the next class of primary affection, the indurated and excavated ulcer of Mr. Hunter, that inoculation can truly be relied upon as supplying a valuable and unerring diagnostic test. Twenty-nine of these ulcers, which may be considered as forming the prototype of primary syphilis, fell under my observation, in all of which inoculation was performed, and in every instance, with but one exception, the characteristic pustule was the result of the operation.

In all these cases, the induration, which gave the sensation of a piece of cartilage beneath the skin, made its appearance before the termination of the first week; and I fully satisfied myself, as far as it was possible by minute investigation into the history of the case, that no plan of treatment, local or constitutional, had been resorted to, to which the superinduction of this cartilaginous hardness might have been attributed. I may further mention, as affording an illustration of the gristly induration of the margins of these particular primary sores, that while engaged in collecting matter for the purpose of experiment, the point of the lancet has been frequently turned from an unexpected jerk of the patient. Thus Mr. Hunter's idea of the specific and poisonous nature of this ulcer has been fully corroborated by inoculation. The next form of primary sore upon which I was induced to experiment, was the phagedenic or sloughing ulcer; of this class ten examples presented, but upon five only was this test instituted. In none of these cases did inoculation produce any decided result; but as the process of reparation had set in in two of the latter instances, no effect could have been expected. The cause of failure in the three cases which seemed favourable for the operation, as also in those which have occurred in the practice of others, I am inclined to consider as explicable on the supposition of the rapid destruction of the parts concerned in the disease, and not from the circumstance of the absence of a specific virus in the ulcer itself, which might militate against the propagation by inoculation of the local affection. The same explanation will, I think, account for the less frequent occurrence of constitutional symptoms as the result of absorption from this form of primary syphilis.

But although specific results do not always succeed to inoculation of this destructive form of ulceration, yet sufficient evidence can be adduced to prove that such consequences do occasionally ensue, and that ulcers identical in character and disposition have made their appearance on sound parts of the body from the introduction of pus from these peculiar sores. Thus, in his experiments on inoculation, M. Ricord adduces the following case, which, as it is one of peculiar interest as bearing upon this precise point, I have taken the liberty of transcribing:—

"Pers——, aged 40, entered April 13, 1834. The commencement of the disease was two months and a half previous, in consequence of an erosion of the prepuce during coition. A chancre appeared; its course was at first regular, but after repeated excesses, and an attempt at cauterization with a burning cigar, the ulcer assumed an acute inflammatory and phagedenic form. At the time of his entry, near the whole surface of the prepuce was affected, but two portions appeared distinctly separated; all the parts touching the roll at the base of the glans presented a gangrenous ring; the remainder presented the characters of a phagedenic chancre, properly so called: all was in the progressive stage.

14th. Some pus, taken from the ring at the base of the prepuce, was inoculated on the right thigh; an application of a concentrated decoction of opium was ordered.

18th. The inoculated puncture had produced nothing; the gangrene seemed checked; some pus was taken from the surface of the prepuce towards the margin beyond the limits of the gangrene, and inoculated on the

left thigh. Dressings of calomel cerate were ordered, and the ulceration from the destruction by the gangrene of a part of the glans and that produced on the frenum by the phagedenic chancre was cauterized with arg. nitr.

21st. The inoculated puncture had produced the characteristic pustule.

26th. The progress of the inoculation, hitherto regular, appeared to assume the *phagedenic form; it was profound and rapidly destroyed the tissues.* Dressings of calomel and opium ointment were used with cauterization with arg. nitr.

30th. There was an improvement; the chlorinated soda was used as a wash, and calomel was sprinkled on the part.

May 9th. The penis was nearly well; the inoculated chancre was in a fair way of reparation."

A case nearly similar to the foregoing is likewise recorded by the same author in the *Clinique Iconographique de l'Hôpital des Veneriens*, where, from the inoculation of the matter from a phagedenic ulcer, a sore was produced upon the thigh which remained unhealed during a period of eight months, the precise time which the original ulcer took in completing its reparation; and in his remarks upon inoculation before alluded to, Mr. Hamilton states that this test should be cautiously resorted to in phagedenic ulcerations, as an ulcer is likely to result "precisely similar in character to the one from which the matter was taken."* In confirmation of this latter remark, he adduces an instance which came under his observation, when in Paris, of an intractable phagedenic ulcer which was caused by the insertion into the thigh of the matter from a primary phagedenic sore, and a parallel case which occurred in his own practice during the course of his experiments, and which was followed by like unpleasant consequences. Lastly, in the recent edition of his work on Syphilis, Mr. Acton cautions us, under any circumstances, against the inoculation of what he terms gangrenous, or serpiginous sores, as in so doing the surgeon may produce an intractable ulcer that may continue for years. From the preceding observations, it will be evident that phagedenic ulcers, under certain circumstances, are capable of being reproduced by inoculation; and when this effect results upon the operation it always gives rise to a sore possessing the same characters as those from which the pus had been taken. This fact would go far in establishing the point, that a peculiar and appropriate poison was generated by the pus of this particular ulcer, and this is borne out by the sequelæ of this affection, which, for the most part, exhibit a marked diversity from those which we generally encounter as the results of other forms of primary infection; as this is a subject to which I shall have occasion more fully to address myself on some future occasion, when speaking of the constitutional or secondary effects of the virus, I shall not at present enter upon its consideration. From a careful review of the experiments instituted, both by myself and others, with the pus of phagedenic ulcers, it would appear to me that there is but one stage in which the disease is inoculable, which is the period intermediate between ulceration and reparation, in which the destructive and disorganizing process of sloughing is, to a certain extent, arrested, and in which the virus would seem to concentrate or localise itself in the part primarily attacked. It is on this account that no effect is produced by inoculation in the first stage while the disease is rapidly extending, and eating up, as it were, every contiguous part; but when its destructive ravages are stayed by the powers of nature, or controlled by those of art, the inherent poison acquires a degree of virulence, the influence of which can be readily exemplified on the sound structures of the body.

Previous to taking leave of the subject of inoculation, as considered in reference to primary syphilitic ulcers, it may be well to add, that during the course of those experiments I invariably made use of the solid nitrate of silver on the fourth or fifth day, when I was fully satisfied as to the character of the sore, for the purpose of destroying the artificial ulceration. The only ill-effects which I have ever observed to follow were denoted by an increased inflammatory local determination, which was speedily dissipated by the employment of some simple emollient cataplasm.

The constitutional or secondary and tertiary forms of syphilis, in every form and variety, presented themselves to my notice, and in this department ample opportunity was afforded of testing the efficacy of inoculation. To enumerate their respective characters would be to give a summary of all those affections consequent upon primary infection; it will be sufficient for my present purpose to state that cutaneous eruptions, in every stage, from the incipient vesicle to the matured pustule, together with condylomatous excrescences and suppurating nodes, were submitted to this ordeal. In no single instance was any effect produced by inoculation—a fact verifying in its fullest extent the experiments of M. Ricord on those symptoms of general infection. A question has, however, been propounded which would seem subversive of the conclusions to which those results would naturally and irresistibly force us—viz. the non-contagious properties of secondary syphilis. How does it happen that a child affected with ulcers in the mouth is capable of producing a sore on the breast of the nurse through which the system is subsequently contaminated by the absorption of the venereal virus? or how is it that sores will be occasioned in the mouth of an infant by the ulcerated nipple of a diseased nurse, upon which symptoms denoting constitutional taint will quickly supervene? To these queries, the only reply which the present state of our knowledge permits us to give is, that such cases must be viewed as forming exceptions to the general rule; for my own part, while I freely admit that I have been unable to produce any result by inoculation from the pus of these particular sores, I am disposed to think that future investigations, directed more especially to the character of the primitive mammary ulcer, may tend to explain away some of the difficulties and clear up some of the doubts with which those interesting phenomena are at present beset: and this assurance I draw from a circumstance which always seemed to me peculiarly striking, which is that the form of ulceration observable in this species of disease presents a marked contrast with other varieties affecting the gland; while fissures and abrasions from local causes are often met with in and about the nipple, this specific breach assumes the ulcerated and excavated characteristics of the true primary venereal ulcer, and in some instances well-defined indurated margins are superadded.

From the foregoing observations and experiments, the following deductions may be drawn:—

1stly. That the virus of gonorrhœa is different in its nature and properties from that of chancre, inoculation with the former never giving rise to a specific ulcer; while that of the latter, when inserted beneath the skin, during the stage of ulceration, is generally succeeded by the characteristic pustule.

2ndly. That abrasions of the mucous membrane are likely to ensue from the irritating quality of a gonorrhœal discharge in its early or incipient stage; that although no appreciable effects result from the inoculation of these excoriations, still mild forms of secondary symptoms have been observed to supervene on this affection, where no other species of disease could be detected on most careful and repeated examinations. In no case, however, has the matter of gonorrhœa produced venereal ulcers.

3rdly. That sufficient testimony has been advanced to prove that those constitutional affections, reported to have resulted from gonorrhœa alone, have been caused by concealed urethral chancres, and not by any specific virus contained in the discharge, and hence has arisen the mistake of recommending the employment of mercury for the cure of uncomplicated gonorrhœa.

4thly. Sympathetic buboes, usually consequent upon gonorrhœal inflammation, are uninoculable, although even here a mild description of secondary symptoms is occasionally met with.

* Dublin Quarterly Journal of Medicine, May 1847.

5thly. Buboes, the result of absorption of the poison of a venereal ulcer, can *generally* be inoculated, provided the operation be conducted in accordance with established rules. From the failures, however, which have occurred during the course of these experiments, I am obliged to dissent from the aphorism laid down by M. Ricord, that when applied to the diagnosis of buboes, inoculation may be considered as forming an unexceptionable and pathognomonic sign.

6thly. The superficial non-indurated primary ulcer is sometimes inoculable, at other times not; both description of sores is occasionally followed by mild constitutional symptoms.

7thly. That in the indurated and excavated ulcer, inoculation supplies a valuable and unerring test, the characteristic pustule being always the result of the operation.

8thly. That the cause of failure in inoculation of the pus of phagedenic ulcers has been probably owing to the time at which the matter was taken—viz., at a period when the process of ulceration was rapidly advancing, whereas the most favourable opportunity would seem to be in the intermediate stage, between ulceration and reparation, when the virus would appear to concentrate itself. The ulcer produced by inoculation is identical in its nature with that from which the pus is taken.

9thly. Secondary and tertiary symptoms produce no effect upon inoculation.

10thly. If the inoculated part be freely touched with nitrate of silver previous to the fifth day, no ill-consequences are likely to ensue.

In bringing to a close those remarks on inoculation, as constituting a differential diagnosis in the various syphilitic affections alluded to in the preceding pages, I cannot more appropriately do so than in the words of Mr. Parker:* "In the present state of science all we can say is, that certain ulcers, the result of sexual intercourse, and not distinguished by their external characters from other ulcers, equally the result of sexual intercourse, yield a characteristic pustule by inoculation; but the ulcers which do not yield the characteristic pustule, are equally liable to be followed by secondary symptoms, and are equally benefited, under many circumstances, by mercury."

In a practical point of view, the experiments alluded to must be looked upon as invested with a considerable degree of interest. To the mercurialist who pertinaciously persists in the indiscriminate employment of his so called panacea, the facts which have been elicited by inoculation are calculated to make him pause, ere he submits to the same trying ordeal every form of ulceration which he may encounter as the result of impure sexual intercourse. To the non-mercurialist, who, endeavouring to avoid one error runs into the opposite extreme, they are designed to remind him that he cannot, with safety to his patient or with credit to himself, discard the use of a remedy, which in many cases exerts a salutary influence over the disease which he undertakes to cure. And to the practitioner who has studied aright the laws which regulate the animal economy in health and disease, and has reflected upon the effects of the introduction of animal poisons into the system, they are destined to enlarge those ideas to which reasoning and analogy have led him, and to point him to a scientific and more enlightened mode of treatment. The charlatan shall then no longer lay claim to the legitimate province of the surgeon, as syphilis shall be no longer the *opprobium* of medicine.

Ursine Ophthalmology and Chl[illegible] well-known bear, belonging to the Zoological G[illegible] Berlin, being affected with cataract, a surgeon volunteered to operate. The animal was then secured with some difficulty, but when tied down, was soon brought under the influence of chloroform. When the patient was insensible, the operator proceeded to extract the lens, but the bear died almost immediately from the effects of the chloroform. The usual means for reviving him were resorted to, but to no avail. An operation of the same kind was performed in London by Mr. White Cooper, and with more success." How much more?

* The Modern Treatment of Syphilitic Diseases.

MEDICAL SOCIETY OF LONDON.

A Visitor exhibited some Tambac, "a valuable therapeutic agent," of which he gave a very flattering account, and declared that it was useful in various diseases: he had obtained it from the Persian ambassador. The specimen brought before the meeting was nothing more, however, than a mild species of tobacco, grown in the neighbourhood of Shiraz, and held in much estimation by those addicted to the Oriental mode of of smoking. *Tambākū* is the well-known Eastern name of tobacco, and though the Shiraz specimen submitted be milder in properties than either the American or Syrian varieties, there is no ground for thinking that its volatile alkaloid principle is at all different from nicotiana, even though possessing, as was asserted, a sedative expectorant action, resembling in this respect the lobelia.

CLOSURE OF THE FISSURES IN THE BONY PALATE—REDUCTION OF A DISLOCATED FEMUR.

Dr. Bauer, a German physician and surgeon, brought before the Society two important improvements in operative surgery, which had been communicated to him by Dr. Buchring, the nephew of the late illustrious Dieffenbach. The first is an operation to effect an organic closure of the fissura palati dura; and it has been successfully performed, more than once, by Dr. Buchring, who appears to be its inventor. Dr. Mason Warren of Boston, has proposed an operation for the same purpose, to be effected by transplanting a portion of the mucous membrane of the roof of the mouth across the fissure, and mentions some successful cases; but the operation has failed when tried in England, Germany, and in other countries. Up to the present time, only mechanical appliances by means of obturators have been used, to prevent the communication between the cavities of the mouth and nose, and the consequent diffusion of sound in speaking. Useful though the obturators may be, yet they are attended with many inconveniences to the patient. In this respect Dr. Buchring's operation deserves high consideration. It may be remarked, that he does not operate before the tenth, nor after the twentieth year, the bones being at that time of life in a comparatively elastic condition. The operation is particularly intended for fissures in the median line of the palate, the vomer not being in connexion with either of the edges of the fissure; but modifications may be easily introduced hereafter to meet those cases where this connexion does exist. A pair of forceps of a peculiar form are required to perform the operation. The patient is to be seated in a chair; the forceps are then introduced into the open mouth, one branch being passed into the nasal cavity, as near as possible to the alveolar process, while the other is to occupy a corresponding position in the mouth, so as to embrace the palate between the two cutting edges of the forceps. The palate is then to be cut entirely through, the opening made being of a corresponding length to the fissure. It ought not to extend beyond the hard palate posteriorly, and ought to leave its anterior portion entire. This opening is to be made on both sides of the fissure. A piece of leaden wire is then to be passed through one of the wounds into the nasal cavity, and so on, through the other, into the mouth again, where the two ends are to be bent upwards. The wire is to be gradually drawn together, the effect being, that as the edges of the fissure approach each other, the space between the margins of the wounds will become wider; or wedges of soft wood may be introduced into the wounds for extending them, instead of the leaden wire. When the edges of the fissure are near to each other, they are to be cut, in order that they may unite as in hare-lip, or caustic may be used to effect the same purpose by granulation. Of course, while this is being done, the same pressure is to be kept up until a complete consolidation of the cicatrix takes place; the pressure being afterwards gradually decreased. The wounds will soon fill up with callus, and close.—The second is an entirely new apparatus for immoveably fixing the pelvis, while a luxated femur is being reduced. In cases of recent and sudden luxations

this apparatus may not be absolutely requisite; but in chronic luxations, where the reduction of the caput femoris can only be effected in the course of weeks or months, especially in those luxations arising from coxalgia, this apparatus will be found invaluable. The present method of establishing counter-extension is not only insufficient in regard to fixing the pelvis, but is intolerable to the patient when he has to endure it for a length of time, whereas Dr. Buchring's invention not only perfectly fixes the pelvis, but may be used for any length of time without causing any inconvenience whatever. While the apparatus is in use, and the femur is being extended, this invention throws the whole force of the counter-extension upon those parts of the body best calculated to bear a great amount of pressure without inconvenience—namely, upon the tubera ischii. The apparatus is made in the following manner:—First a model is taken with plaster of Paris, of the posterior surface of the pelvis, extending so far inferiorly as to include the tubera ischii. From this model an exact impression is to be taken in cast-iron, so that it will fit exactly to the corresponding parts without any undue pressure on any portion of the surface. From the superior ridge of the plate of iron two strong curved pieces of iron are to be brought round the pelvis as far as the anterior superior spine of the ilium, keeping at a distance of about two inches from the body. At each of the two ends there is to be a screw, capable of being turned by the hand, armed with a well-bolstered pelote, and the screw is thus to be turned until it becomes firmly fixed upon the anterior superior spine. The apparatus is to be fixed to the bed, and the extension may then begin.

INFLAMMATION AND ULCERATION OF RECTUM: IMPROVED SPECULUM RECTI.

Mr. Coulson said, that in September last, he saw, with Mr. Haden of Sloane-street, a patient, aged 34, who passed a semi-solid feculent motion once in twenty-four hours, tinged with mucus and blood, and in addition to this, within the same time, four or five evacuations consisting solely of small quantities of mucus and blood. On examining the bowel with the speculum, it was found that the mucous membrane was destroyed to the extent of two inches from the anus, and pus and blood were seen exuding from the ulcerated surface. Various local and constitutional remedies were employed with little relief except a slight diminution of the discharge. It was then suggested that the decoction of tormentilla should be tried; three ounces of this root in a pint and a half of boiling water were boiled down to a pint, and four ounces of the decoction were thrown up the rectum twice a day, and retained each time a quarter of an hour. Under the use of this remedy the pus and mucus gradually diminished, and within five weeks the ulceration had completely healed; the only medicine taken during this time was a little castor oil, to keep the bowels loose. Mr. Coulson believed the rectum to be occasionally the seat of inflammation, attended with muco-purulent discharge, which, if unchecked, proceeds to the destruction of the mucous membrane of the bowel, and to the formation of abscesses in the neighbourhood of the anus. A frequent desire to go to stool exists in these cases; and unless this be yielded to at once, the motions come away of their own accord, loose, and mixed with blood and mucus; at last the patient's health gives way, and he is worn out by continued suffering. Mr. Coulson showed a preparation taken from a patient who had died of this complaint: the cellular tissue round the anus was hardened, the mucous membrane of the rectum completely destroyed, and the internal surface of this bowel presented elevated hypertrophied muscular fibres, between which there were several openings communicating with external abscesses, so that these in fact were the result of the disease of the interior of the gut—the diseased action without being continuous with that within. The ulceration of which he had been speaking was not to be confounded with the fissured rectum which often occurs from mechanical causes, or the ulcerated rectum which is sometimes found in persons labouring under a syphilitic taint. These conditions of the bowel were very painful, and the source of great distress to the sufferer, but they easily yielded to remedies,—as the black oxide of mercury ointment (one drachm of the black oxide to an ounce of lard), or if this failed, to a division of the surface of the ulcers,—and when left to themselves did not destroy the patient. Mr. Coulson said it was most desirable, in all diseases of the rectum, to make an examination of the bowel with the speculum; and he would take this opportunity of showing one which was a modification of Mr. Hilton's and Mr. Curling's. The difference consisted in the handle being loose, so that the same instrument could be used for any part of the bowel, which was not the case when the handle is fixed. This alteration was suggested by Mr. Hovell of Clapton.

The instrument is of a conical form, four inches long, three-quarters of an inch at the small extremity, and an inch and one-eighth at the large. Upon the larger end is a ring, two inches and a half in diameter, with one-third of its circumference removed. In this ring are seven holes, half an inch apart, into either of which the handle can be screwed, thus permitting the handle to be placed at any inclination to the opening in the speculum. This is of use sometimes; for when the handle and the opening are in the same line, the latter is in the way of the patient's thighs. In the speculum is an opening, one inch at the largest end, and three-quarters of an inch at the point. Into this is fitted a metal plug, which just fills up the opening, so that a perfectly conical tube is formed for introduction. After introduction, the instrument is turned round until the plug is just opposite the ulcer; the latter is then withdrawn, and the diseased portion is then very clearly seen falling just into the opening of the speculum. No attempt to introduce the plug while the speculum is in the rectum should be made; but the finger should be passed into the speculum for the withdrawal.

THREE CASES OF RESECTION OF BONE.

By C. P. Johnson, M D.,
Professor of Anatomy and Physiology, Sydney College, Richmond, Virginia, U.S.

The following cases are reported, not because of any peculiar interest which attaches to any of them, but for the purpose of adding to the statistics with reference to an operation which has, perhaps, been too much neglected in this country:—

Case. 1. *Resection of the Ulna.*—Rose, a negro girl, aged 11, has been suffering for four years with a chronic inflammation of the right arm over the ulna. The disease was originally attributed to a fall or a blow which she received on the arm. The arm has occasionally suppurated, and from time to time, during the last year, several fragments of bone have been discharged.

When first presented to me, April 18, 1849, there were two fistulous openings on the under side of the forearm, one about two inches below the elbow-joint, and the other about an inch lower down, through which the probe passed freely down to the denuded ulna. Neither the elbow-joint nor the radio-ulnar joint below, seemed to be involved in the disease. The general health of the child had now begun to suffer, and it was evident that she could not long stand the continued irritation to which she had already so long been subjected.

On April 21st I exsected the middle two-thirds of the diseased bone, the patient being placed fully under the influence of ether. The operation was performed by making two semi-elliptical incisions, extending from a point a few lines below the internal condyles to the styloid process of the ulna, meeting at their extremities, and including between them the fistulous orifices and the diseased integument; then dissecting away the integuments and muscles from the anterior and posterior surfaces of the ulna, dividing this bone just above its styloid process with the metacarpal saw, separating its attachment to the interosseous membrane, and completed by making the upper section of

the bone with the chain-saw, just below the coronoid process. But little blood was lost, and only one vessel required the ligature. The edges of the wound were then brought together by adhesive strips, and an angular splint applied, extending beyond the ends of the fingers.

With the exception of fever, accompanied with slight delirium on the second day after the operation, which was speedily checked by a mercurial cathartic, the patient recovered rapidly, and was discharged about eight weeks after the operation entirely well.

By adopting the operation of exsection in this case, the elbow and the wrist-joints were both saved to this patient; and before her discharge she could use them both freely. Before the introduction of the operation of exsection, this arm would have been amputated, probably above the elbow.

Case 2. *Resection of two-thirds of Inferior Maxilla.*—In July, 1850, I was asked to see Mary, a negro woman, æt. 35. She gives the following history of her case. About twelve months ago, while in New Orleans, she had the first molar tooth of the left side of the lower jaw extracted: she states that in the operation a portion of the alveolar process was broken off, and that from that time she has suffered constant pain and swelling in that side of the face, with occasional discharge of small pieces of bone.

When I saw her, the left side of the face was much swollen, and the whole region of the left side of the inferior maxillary bone the seat of much induration; there was a fistulous orifice externally along the lower margin of the bone, about half way between the angle and the symphysis, which communicated with the diseased bone, and another orifice which opened internally on the gum, whence the molar tooth had been extracted, which also communicated with the denuded bone and with the other sinus.

On the 12th of July, hoping to be able, by a simple operation, to remove the whole cause of the trouble, I made an incision over the seat of the disease, and finding that a large portion of the thickness of the bone was involved, took out an entire section, of a V-shape; after the external wound resulting from this operation was entirely healed, as it was in three weeks, there still remained a fistulous orifice in the mouth, which was found to communicate with denuded bone; from this orifice several pieces of necrosed bone were from time to time extracted, without, however, affording any permanent relief to the patient, whose face continued much swollen and very painful. In a few days, an external orifice again made its appearance, from which a considerable quantity of pus was discharged daily, and which was found also to communicate with denuded bone.

Upon a careful examination of the case now, it was ascertained that the whole left side of the body of the bone was in a state of hypertrophy, the disease extending across the symphysis to a point between the right lateral incisor and the canine tooth of the same side in one direction, and to the angle of the bone in the other.

Upon consultation with my friends, Drs. Marx and Gibson, it was determined that the safety of the patient depended upon the entire removal of the disease, and that to effect this with greater certainty, it would be better to disarticulate the bone at the temporo-maxillary articulation, and to resect the body just to the right of the diseased portion.

Accordingly, on the 2nd of September, I proceeded to do the operation as follows:—The patient being placed in a suitable chair, and put thoroughly under the influence of chloroform, an incision was made commencing opposite the left temporo-maxillary joint, passing downwards along the ramus a few lines below the angle, thence, slightly curved with the convexity downwards, horizontally along the inferior edge of the body of the bone, to the right side of the chin, and thence upwards to the right angle of the lip. The dissection was then made from below upwards, so as to penetrate the cavity of the mouth, and to expose the whole of the anterior face of the diseased mass. A slight dissection and the use of the fingers enabled me to detach the soft parts from the posterior face of the bone along the portion at which the section was to be made. This accomplished, the first incision was extended through the lower lip,* the flap turned back and held by an assistant, the chain saw passed behind the bone just anterior to the first bicuspid tooth, and the bone rapidly divided at that point. The internal attachments of the bone were then speedily divided, and the operation completed by the division of the attachment of the temporal muscle to the coronoid process and the disarticulation at the glenoid cavity. This stage of the operation was greatly facilitated by using the bone itself as a lever, to put upon the stretch the parts to be divided and to pry out the coronoid process from under the zygoma.

No vessel required ligaturing. The edges of the coronoid were brought together with sutures and adhesive strips, a light dressing applied, and the patient put to bed, after the administration of a stimulant, in a tolerably comfortable condition.

During the operation, a thread was passed through the arteries of the frenum of the tongue, in case retraction should take place; but although the bone was divided some distance to the right of the symphysis, and consequently the anterior portion of the genio-hyo-glossus muscle necessarily divided, no retraction of the tongue took place, and no symptoms of suffocation occurred.

Upon an examination of the bone after the removal, it was found in a state of hypertrophy, the cancellated portion and the dental canal in the left side being filled up with dense compact laminated bone structure. Though but seven weeks since the first operation, the space left by the removal of the section of bone at that time had become firmly filled with cartilaginous tissue.

The patient did well, and on the 17th September, just two weeks after the operation, the wound was completely healed. There remained, however, partial paralysis of the left side of the face owing to the section of the portio dura, and a good deal of swelling, with some eversion of the lower lip. The condition of the lip was entirely relieved in the course of a few weeks longer by the use of adhesive strips, and the paralysis gradually diminished, though it has not entirely disappeared.

Case 3. *Resection of the ununited ends of a Fractured Femur.*—The patient, an athletic Irishman, aged 19, had suffered just three months and ten days before, a very oblique fracture in the upper third of the right thigh, in a direction from above downwards and forwards; the fragments were consequently, at the time of the operation, very far separated from each other, the lower fragments being drawn upwards and inwards.

Having placed the patient fully under the influence of chloroform, the operation was commenced by an incision extending from the trochanter major to the outer surface of the external condyle. This incision extended down to the fascia lata, which was then divided continuously with the first incision. In order now to reach the lower end of the upper fragment of the fractured bone, which was drawn forwards and outwards, the vastus externus was separated from its attachments to the rectus femoris, and held back by an assistant. With some little difficulty the extremity sought for was found, a chain-saw passed around it about an inch from its termination, the section readily made, and the fragment separated from its ligamentous attachments and removed.

The next step in the proceeding, in the section of the upper extremity of the lower fragment, proved very difficult, in consequence of the great retraction of this portion of the fractured bone. This lower fragment was found drawn up to the lower portion of the gluteal region, and car-

* Anxious to preserve the integrity of the lower lip, if possible, I attempted to pass the saw without dividing it, but found that the extreme thickness of the bone and the small curve of the needle used rendered it impossible. I was obliged, therefore, to divide the lip in order to obtain more space for manipulation.

ried by the adductors considerably inwards, rendering its access by an external incision difficult. Finding it impos sible to reach the upper portion of this fragment through the separation already made between the vastus and the rectus, the vastus was separated from its posterior attachments and turned forward. After a tedious dissection, in which the handle of the scalpel and the fingers were used very much to the exclusion of any cutting instrument, in order to avoid the risk of dangerous hæmorrhage, the extremity of the bone was at length reached, and with some difficulty, owing to its very great depth, the chain-saw passed around it. This portion of the operation was much facilitated by carrying the foot across the opposite instep, so as to force the fragment sought nearer to the external surface of the thigh. The chain-saw turned down both in front and behind, by the thick muscles of the thigh, was worked with difficulty, and, before the section was completed, broke. A good metacarpal saw which was at hand was substituted, and with it the section finished. The detached portion, about an inch and a half in length, was then easily removed. The two opposite ends of the bone, thus rendered perfectly transverse, could then be brought accurately into contact, producing a shortening of the limb of about two and a half inches.

The next step in the operation consisted in boring with a small bit and brace a hole in each of the ends of the bone thus approximated, through which a very strong silk ligature was passed by means of an eye-probe, and finally tied. The holes were bored obliquely, commencing each about half an inch from the sawn extremity, and passing the one upwards and the other downwards, terminated in the medullary canal. The ends of the ligature were brought out of the wound. The edges of the wound were then brought together as accurately as possible, the limb lightly bandaged, a long splint applied along the whole posterior surface of the limb, and the patient put to bed, with the leg resting upon a slightly inclined plane.

During the operation, a good deal of blood was lost, a large portion of which was venous; and after its completion, the patient who had then recovered from the effect of the anæsthetic agent, was very pallid and excessively prostrated. Brandy and water was freely administered, and warm clothing applied. Reaction took place very slowly; about four hours after the operation, the pulse began to rise and the skin to regain its warmth. The stimulants were then used more moderately. The reaction, however, was never complete, and only lasted a few hours. During the night the pulse again began to flag, and the patient became more restless; stimulants were again resorted to and used very freely, but with no effect. The system seemed to have lost its power of responding to any agent, and in spite of the most active stimulant treatment, the patient continued gradually to sink, until about six o'clock the next evening, just thirty hours after the operation, he died. No post-mortem examination could be obtained.—*Phil. Med. Examiner.*

REVIEWS AND NOTICES OF BOOKS.

THE PREVENTION AND CURE OF MANY CHRONIC DISEASES BY MOVEMENTS. By M. Roth, M.D. London. 1851. 8vo. pp. 302.

Under the names "Kinesipathy" and "Kinesitherapie," the novel method of treatment which forms the subject of the volume before us was first promulgated to the profession. It is in point of fact little else than an improved and more scientific application of gymnastic exercises, which however useful they may prove in invigorating the frame, in strengthening the muscles, and in relieving certain deformities, can have little curative effect upon disease.

It is not pretended (Dr. Roth observes) that this is a complete treatise on the subject of movements as regards all their relations to the body in health and in disease. "He has contented himself (he says) with compiling from every available source whatever seemed to him to be of value," and "the mere fact that this method of treatment is insufficiently known to the profession and the public, is sufficient excuse for this publication."

The subject is considered under three heads. The first contains a short history of the treatment by movements before and since the time of Ling, with a biographical notice of the latter; under the second, "the doctrine of the general and specific movements and their effects" are considered; the third is devoted to the "treatment of certain diseases by movements."

The following is Ling's division of the doctrine of movements, he being regarded as the great authority upon all points connected with this subject. He arranges them in four principal groups, "according to the state of the organism, and its relation with the external world":—

"1. *Subjective-active state*, which supposes the organism to be acting upon itself with its own force, for the purpose of self-conservation and development. This is the base of the

(a) Pædagogical part, by which we learn to subject the body to the influence of our own will, and by which the natural disposition to harmony in its various parts is developed.

2. *Objective-active state.*—In this the action is the result of a combination between our own force and one that is external, which latter is striving to bring on a re-action. This is the base of the

(b) Military part, by which we learn to subdue by the assistance, either of external means (as weapons) or of our own bodily force, another will external to our own; here the oneness of the body and the weapon are developed proportionately to the action of our opponent.

3. *Subjective-passive state.*—Here the organism is in an abnormal or diseased state, during which we are less able to act ourselves, but must remain passive, and receive a mechanical influence from without. This is the base of the

(c) Medical part, by which we learn to allay or cure our pains and disorders, either of ourselves by a convenient position of the body, or with the assistance of others acting upon us by movements; whereby the harmony which had previously been deranged by the respective irregular proportions is restored to the different parts of the body.

4. *Objective-passive state*, in which we express by outward actions our feelings and impressions. This is the base of the

(d) Œsthetic part, by which we express actively our internal being, our thoughts, and feelings; thereby showing the harmony which exists between our intellectual and corporeal being."

The author next gives a classification of movements, which he divides into "simple, compound, double, and half movements; partial, parallel, and general movements; repeated, rhythmical, and movements in motions."

We have then a "division of movements with respect to the moving power," into "active, passive, combined, and mixed movements." The "general effect of movements" is considered under the heads "physical effect, physiological effect, and psychological effect;" followed by an account of the effects of active, passive, and combined movements.

The indications for treatment by movements form the subject of the next section; they are either general or special. The special indications for this method of treatment are—

"1st. Restoration of the right shape and form; as, for instance, of curvatures.

2nd. Restoration of the right position and direction of the parts; as, for instance, of ruptures.

3rd. Restoration of the mobility of the parts; as, for example, incomplete anchylosis.

4th. Removal of solid and liquid matters and foreign bodies from the cavities and textures of the body.

5th. Restoration of nutrition, assimilation, and reproduction of the whole body or single parts.

6th. General change of substance, principally of the muscular fibres.

7th. Increase of the activity of the skin, lungs, heart, liver, &c.

8th. The diminution and increase of the activity of the nervous central organs.

9th. The alleviation of pains."

The active movements are used in order.—

"1st. To strengthen and fortify a muscle; that is, to form new and stronger muscular fibres.

2nd. To remove the fat texture which has been substituted for muscle.

3rd. To effect a stronger innervation of the motory nerves.

4th. To increase the temperature.

5th. To promote the formation of arterial blood in general, and improve its mixture.

6th. To derive blood, principally the arterial, from neighbouring organs.

7th. To effect a better formation of venous blood, and an increased circulation of it, as well as of the fluid of the lymphatic vessels, not only in the muscles but also in more distant regions of the body.

8th. To relieve the contraction of certain muscles by strenghtening their antagonists.

9th. To establish, by the returning equilibrium of the antagonists, the re-formation of the texture of the ligaments, tendons, cartilages, bones, and even of internal organs."

Passive movements are used therapeutically:—

"1st. In hypertrophy of the different organs.

2nd. In pseudo formations.

3rd. In the removal of the products of inflammation.

4th. In dilatation of the veins.

5th. In disorders of the valves of the heart.

6th. In muscles and tendons which have been contracted but for a short time, in which the muscular power is to be weakened by the increased resorption."

The description of the different movements follows; the details are given with a minuteness which is somewhat amusing, and figures of the various attitudes or positions are added in illustration of the text. The remainder of the volume is occupied with the application of movements to disease. We shall conclude with the following extract from the section upon "diseases of the eyes," which will enable our readers in some measure to judge of the value of this therapeutic agent:—

"*Inflammations of the eyes, principally chronic conjunctivitis*, have been cured by absorbent and derivative movements. Many cases of specks on the cornea, of short duration, and where the opacity of the cornea was but of small extent, were successfully cured by Neumann, who communicates the following cases, and their treatment.

Case.—A girl, 22 years old, was, according to her own statement, from her infancy so blind, in consequence of variolous ophthalmia of the right eye, that she could not discern broad daylight from the darkest night. There were three spots on the cornea of the size of a pea, which touched each other, and covered the whole cornea in such a manner that only very small transparent spots remained towards the edges of the cornea. One of the opaque spots, situated in the central part of the cornea, was not only distinctly prominent, but also so unequally and differently coloured, that it was plainly a real scar of the cornea; the other opacities had the common white colour of mother-of-pearl, and therefore the cornea appeared very similar to the so-called opal glass. It was impossible, even with the microscope, to examine the state of the iris and pupil. As the conjunctiva of the sclerotic was also metamorphosed in different places by dilated vessels, and no other inflammatory symptoms were to be seen, the excision of some single pieces of it was tried, in order to diminish the nutrition of the scar-texture of the cornea; but this had not the desired effect. The repeated scraping off of the opaque spots of the cornea was equally unavailing; a more or less inflammatory reaction followed, but without changing the condition of the cornea. The medicines employed internally, as well as externally, produced no good effect, and the patient was discharged. After an interval of six weeks she returned, and requested to be operated on, with the hope the operation would succeed. Instead of which, the treatment by movements was employed, and continued for fourteen weeks, the result of which was, that the power of vision was so far restored, that the patient knew the number of the fingers held before her, the colour and form of a pocket watch, &c. At the same time the cornea became so changed, that already many entirely transparent places were to be seen, while others were covered as with a cloud. The black colour of the pupil and the quick movement of the iris (notwithstanding it appeared on the inner edge of the cornea attached to the leucoma) could be very distinctly seen with the eye; the scar of the leucoma was considerably more level, and still more diminished, and there was no doubt that the scar-texture itself disappeared."

The treatment of this case consisted of the following movements:—

"1st. Pressure on the supra-orbital region.

2nd. Passive rotation of the head.

3rd. Frictions in the direction of the longitudinal superior sinus, and transverse, and the beginning of the internal jugular vein.

4th. Flexion of the trunk, with resistance.

5th. Active rotation of the lower extremities.

6th. Percussion on the soles of the feet, with a cylindrical piece of wood."

MEDICAL TRIALS.

HOMŒOPATHY AT TOTNESS—INQUEST.

Rev. James Shore (not sworn)—Says he calls for an inquiry in consequence of his being accused of the murder of the child, or that he had killed it by his treatment, which he will show by his witnesses, and that he will prove himself both justified and qualified to treat any sick person, and to prescribe medicines, having studied medicine for thirty years; that the medicines had cost him formerly fifty pounds, but now he permitted certain ladies to receive money as a remuneration; that those persons prepared the medicines in the breakfast room in his house, from his prescriptions, and delivered the medicines to his patients at his house.

Mr. William Bowden (sworn)—I am a surgeon residing at Totness; I examined the body of Alexander Charles Screach, on the 12th day of November instant; there were no marks of violence externally, no emaciation of the body; skin tinged yellow, generally over the body, giving an idea that the child had jaundice; I then opened the head; on removing the cap of the skull, I found the membranes of the brain congested, the exterior membrane or dura mater was tinged slightly yellow; on removing the brain, I found it quite healthy; I then opened the chest, the lungs were quite healthy, there were no adhesions or appearance of any former disease; the heart was also healthy; the abdominal organs were generally healthy; the stomach contained no food, and only a small quantity of mucus; the vessels of the small curvature were slightly congested, as well as those of the duodenum; the liver was healthy; the gall-bladder was empty, with the exception of a little mucus; the kidneys were healthy; bladder full of rather high-coloured urine; I believe the child to have died from congestion of the vessels of the membranes of the brain.

Mr. W. Kellock (sworn)—I am a surgeon residing at Totness; I attended the examination of the body of Alexander Charles Screach with Mr. Bowden, and agree with him as to the cause of the child's death.

Mr. Shore (asked)—If jaundice might not produce congestion of the vessels of the brain?

Mr. Kellock—Certainly.

Mr. Shore—Might not violent sickness produce the same effect?

Mr. Kellock—Yes, but not permanently; the congestion might be the cause of sickness.

Mr. Shore—You said some of the vessels of the stomach and duodenum were congested, might not that effect be produced by ginger administered internally?

Mr. Kellock—That would depend upon the quantity given; I cannot answer that question unless you state the quantity, which I should think must be large to produce such an effect.

William Screach (sworn)—I am a tailor residing in Bridgetown; I am father of the child; it had been ill since last Monday fortnight; I considered it looked yellow, and had the jaundice; Mrs. Turpin, a neighbour, told me that Mrs. Monteith had a child cured of jaundice by Mr. Shore, or from a prescription of his; my wife took the child to Mr. Shore's house, he prescribed for it, and I sent my son for the medicine to Mr. Shore's house twice; the first time there were twelve or fourteen powders sent, I cannot say which, and the second time twelve or fourteen powders, about twenty-six altogether; the powders were directed to be given every four or six hours, he did not know which; they were given to the child; the medicine produced no apparent effect; there was no alteration in the child up to Wednesday in the last week, it was running about and occasionally lying about very heavy; on Thursday my wife heard that Mr. Thompson

had ordered some medicine for a child of Mr. Butland, chemist, of Totness, for the same disorder, and had soon cured it; she went to Mr. Butland and asked for the same medicine, and received four powders. [The prescription in Butland's handwriting was put in, it was powdered rhubarb, five grains, carbonate of magnesia, five grains, and ginger, one grain.] One powder was given on Thursday evening, one on Friday morning, and one on Friday night, nine o'clock; in the course of half an hour the child vomited very much, and continued in that state for a long time, it was restless for many hours; it then became quiet; on Saturday night it appeared to be much worse, when I sent for Mr. Derry; he came directly and sent it four powders, but he did not say the child was so dangerously ill; I saw it take one of Mr. Derry's powders; it took no effect; the child was quiet until five o'clock on Sunday morning, it then became convulsed, and remained so until seven o'clock in the morning, and died at nine o'clock, about five minutes before Mr. Derry came to my house.

Elizabeth Seycombe (sworn)—Called by Mr. Shore and examined by him; did not say Mr. Gillard had said that Mr. Shore had killed the child; I went to his surgery at Mr. Thompson's for medicine; Mr. Gillard was there and the dispenser; Mr. Gillard said, "so they say Mr. Shore has killed the child (I thought he meant Screach's child); what does he know about medicine;" no name was mentioned.

Gervas Holmes (sworn)—Went with Mr. Shore to Elizabeth Seycombe, fearing she might prevaricate, to hear what she said about this case; she stated having had a conversation with Mr. Gillard, and that Mr. Gillard had made use of these words:—"Mr. Shore has killed the child; what does he know about medicine;" she then varied by saying that Mr. Gillard said:—"They say Mr. Shore has killed the child; what does he know about medicine."

The Coroner then remarked that they must be all satisfied as to the death of the child, and if other parties were aggrieved at Mr. Shore's practising medicine they must apply to another court; and Mr. Shore, if he considered himself charged with the death of the child, must apply elsewhere.

The jury then retired for a short time, and returned their verdict that the child had died from congestion of the membranes of the brain, and that there was not the slightest blame to Mr. Shore.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 10, 1851.

PROCEEDINGS UNDER THE DISPENSARY ACT.

Since our last, the working capabilities of the Dispensary Act have been pretty well tested: and to say the truth, we feel rather relieved than otherwise by the results. No where have salaries been granted to the Surgeons commensurate with the amount of duty imposed on them, and in many places they are utterly inadequate; but upon the whole, the Guardians, in the formation of districts and provision for the relief of the sick poor, have, we confess, done better than we expected. Whatever we may think of some of the Boards, and of some of the Guardians, we are gratified to perceive that, so far as matters have already been handled, there is a display of a much better spirit than that exhibited in England on a somewhat similar occasion. We are now viewing the subject in its general bearings, and more in reference to the financial condition of the department to which it belongs, than in relation to individual cases, or even to the claims of our own profession. We would suggest to our readers a similar exercise of their faculties, and a similar suppression of feeling, while they multiply one hundred and sixty-three by whatever number they may consider the average of dispensary districts in the unions; and then multiply the product by the average of salaries. We do not, by any means, wish to suggest a tame submission to any resolution which sacrifices the interests of the poor or the surgeon to the interests of the ratepayer; all we want is to suggest a consideration of both sides of the question, and we do so the more because we are of opinion that, upon a rough calculation, the total amount of tax about to be levied off the entire country for the relief of the sick poor will not be found disproportioned to its resources, even crippled as they are. We do not think that parsimonious Guardians will find in such a calculation any very convincing argument in support of sordid bargains with Dispensary Surgeons; neither do we think that the Commissioners will find it a ground for the adoption of their views. At the meetings of the Boards throughout the country, there seems to be a fair business-like calculation of profit and loss consequent on the change taking place, and a fair setting off of the former grand jury cess and subscriptions against the proposed poor-rate for the same purpose; and it is in this spirit the Dispensary Surgeon should meet the ratepayer, proving to him that he can afford to be just, and, in many cases, even generous, without sustaining any loss by the transition from the old to the new system. There seems also to be a good feeling and good temper displayed which we should not be the persons to disturb. There may have been a little exhibition of peevishness by crabbed economists here and there, and now and then a fling at "the doctors;" but there is none of the swaggering or offensive depreciation of medical services formerly indulged in. We have before us a mass of information as to these proceedings, which we cannot well use without devotion of too much of our space to the subject, or without accumulating details which may lead to confused conclusions. We select a few of the reports as they have reached us. In Belfast, Dr. McGee's proposal to grant salaries of £100 to the Surgeons, was met by a Mr. Gregg after the following fashion:—

It might (he said) be all very well to cry out "don't mind the money;" but he confessed *he did mind the money*. They had had the poor properly attended by qualified medical men for a number of years; and now, when the funds were to come out of the rates, he considered it a strange proceeding that they should consent to advance their salaries. They had plenty offering themselves for the situations at present; and although it might be all very well to slight the expense of 1½*d.* in the pound, still the light he viewed it in led him to move, as an amendment, that the salary be £70.

Mr. Robert Thompson suggested an alteration of the figure to £75, which was adopted: and he then seconded the motion.

Mr. Posnett's opinion was, that the proposition then before the house should be adopted. *The situation would be the means of bringing young medical men into notice*: and he confessed that he thought £75 a liberal allowance.

Mr. Senior also agreed in viewing the standard of remuneration as a liberal one. It was high when compared with those paid in England, when the population was equal; these were considered fully equal to the duties by the profession, while they were not regarded as too heavily pressing on the ratepayers. He repeated that he looked upon £75 as exceedingly liberal.

The question was then put, as between £75 and £100; when the former sum was carried by a majority of 19 to 2—the mover and seconder only supporting the figure.

Doubtless Mr. Gregg "minds the money," and has a very praiseworthy horror of three halfpence in the pound. Mr. Posnett, too, has an eye to business, when he pays the young doctor by "bringing him into notice." Do young spinners and bleachers sell webs cheap to bring them into notice? Then Mr. Inspector Senior again puts in his oar. We have to suggest that the Commissioners will find out something for this gentleman to do to entitle him to

his salary; his loitering about here meddling with other men's business is most improper. We have heard something about the jealousy of General Inspectors caused by the appointment of Medical Inspectors, which makes us dislike this display of Mr. Senior's notions of duty. In Sligo Union salaries of £100 have been voted. Upon this a local paper, the *Sligo Chronicle*, remarks:—

It will be seen by our report of the proceedings of the board of guardians, that the salaries of the medical officers are to be £100 a year each. This is really monstrous. We venture to say that, under the dispensary system, they did not receive each £50 a year. What will the ratepayers think when in the flourishing union of Belfast the salaries are £75 a year,—nineteen guardians voting for £75, and only two for £100? And this remuneration, the poor-law inspector stated, *was higher than was paid in England.* The guardians here have made a great mistake,—we will not use a harsher word. Is the struggling union of Sligo to pay larger salaries than any paid in England or Belfast? Surely the Poor-law Commissioners will never sanction this. To be sure they have always been for high salaries, but the present are a little beyond anything they have hitherto directed. We have been given to understand that a public meeting will be called in reference to the affair.

This is just what we said would be the effect of the Belfast proceedings, and the very improper interference of Mr. Senior. This Inspector had no business whatever to throw the weight of his official influence into the scale, or to embarrass his superiors by premature expression of opinion. In Tubbercurry Union two districts have been formed, and salaries of £100 a year voted to each of the Surgeons. In Tullamore Union five districts have been formed, but Surgeons' salaries seem not to have been declared; and in Parsonstown eight. In Naas the division has been into seven, and the salaries vary from £50 to £75. At Abbeyleix, in the Queen's County, the union has been divided into eight districts, but salaries are not yet named; the following pertinent observations were made here by Mr. Lalor, formerly member for the Queen's County, a man competent to form a sound opinion on such subjects, and a vigilant guardian of the rights of the labouring classes; by the Hon. Thomas Vesey, one of the present members, a kind and considerate friend of the poor; and by Mr. Bland, a gentleman in every respect well qualified to deal with such a subject:—

Mr. Lalor said, I was in hopes that some gentleman would propose a larger number of districts than four; I would say seven, as being the number of the present ones. I took some trouble in forming the divisions, and in making them out have stuck as close as could be to the present dispensaries. It was not the voluntary kind of attendance that was heretofore the rule that should now be the rule of medical men; the poor people must be attended in and out of their houses as the occasion may require. If the guardians made the districts unwieldy, so that no man could conveniently reach them, it would be an absurdity to expect that the people could be properly attended to. If they began at four they would ultimately have to increase to seven, under the compulsion of the Commissioners, or the coercion of circumstances.

Mr. Vesey said, each question has its difficulty. On one hand you have the taxation to consider, and on the other the comfort and wants of the poor. Besides you will have not only the medical wants of the destitute poor, *but of the deserving small farmers and the hardworking and labouring portion of the community.* Increase of taxation is an important consideration, but it is not more important than the wants of the people. The wants of the poor will require a greater number of districts than four; for the medical officer will not only have to give the poor medicine but be bound to attend them at their houses, on a ticket from any of the guardians or the committee. No one medical man could or ought to be expected to do all this: and if two doctors have to be engaged for the one district, I do not consider it would be any economy; therefore I will vote for Mr. Lalor's motion.

Mr. Bland said, my first impression was in favour of the larger districts; but after all I have heard I think it my paramount duty to vote for the motion which will afford the greatest relief and comfort to the poor. I would be very sorry to press upon the ratepayer, but the county cess will be diminished in the union by the removal of the £800 a year which had been collected for the dispensaries, besides the levy for vaccination will be at an end. These will be some compensation to the ratepayer. It would be impossible for a medical man to answer in any reasonable time calls from persons in the extremes of a large district. Though we would commence with one medical man, a second would have to be appointed, so we would then have eight instead of four. Under the consideration, as Mr. Vesey states, of a proper attention to the wants and comforts of the poorer class, being our chief object, let us waive personal considerations and vote for the motion which is likely to confer on those the greatest benefit.

At Trim a point of some importance has been mooted:—

A letter was read from the Commissioners, referring to the inquiry of the board, if they have the power of providing more than one house or place in each dispensary district for administering medical relief. The Commissioners are of opinion that the dispensary district should be formed so as to admit of the attendance of sick persons resident in each district at one building in a central position, which would serve as a dispensary or for meeting of the dispensary committee. They state, however, that they will take into consideration any arrangements which the guardians may think proper to make in reply to their circular of 12th November.

Carlow has been divided into six districts, but salaries have not been named; and Mountmelick into eight; Banbridge into six, with salaries varying from £50 to £80. Our limits do not permit us to go into further detail, especially as we are anxious to give insertion to the following letters:—

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I consider it incumbent on the dispensary surgeons of the different unions in Ireland to avail themselves of your invitation, and give you the proceedings taken by the boards of guardians in working the new dispensary act. Therefore I have to inform you that on last Tuesday week the guardians of this union divided it into seven districts, continuing the same number of dispensaries as existed prior to the new law. The districts are, on an average, about eight miles by eight (some rather under, and one a little over); population varying from over 9000 down to 3724, the average being about 6500. No sum has as yet been fixed as a salary, but in a conversation at the board, the majority of the guardians named £80 a year as the doctor's salary, and an allowance of £20 a year for an office and medicine. There is, evidently, an inclination to act liberally and justly towards the profession and the poor, irrespective of the additional fraction of a penny that may, in consequence, be imposed. When the act is in full operation, the poor-rate will be increased 1.5-16ths in the pound, according to the scale of salary before mentioned. The only injury that the medical attendants in this union may suffer, would be if the guardians delay enforcing the law until after the spring assizes—a contingency that was hinted at the last meeting of the board; but I trust that the medical officers of every union in Ireland will, if necessary, memorialize the Commissioners to date their salaries from the first of October, as I dare say many others are circumstanced as I am—viz., working for the *past four months* without remuneration, as the dispensary to which I am attached fell into debt some four years since, and is but now out of it. This being the usual time for getting in the subscriptions to be presented for at the spring assizes, those whose grant is now expired will have neither subscription nor salary to meet their exigencies unless the Commissioners date their salary from the first of October.—Your obedient servant,

Mullingar Union, Dec. 5, 1851. D. D.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I am glad to find by the last number of your useful periodical that you have thrown off all unnecessary reserve respecting the proceedings of boards of guardians in carrying out the new dispensary act, and I trust your readers will avail themselves of your invitation to publish the movements in every locality. Many, yourself among the number, expected great improvements from the operations of the new act, and possibly cases will occur to justify your expectations;

in many more, however, disappointment will, I fear, result—disappointment to the doctors and disappointment to the poor, unless the Commissioners fix some equitable standard to guard the interests of both. This union (Glin) has been divided into two districts—Tarbert and Shanagolden; salary for the former £70, for the latter £60; and these salaries have (as I am informed) been sanctioned by the Commissioners. Now, I know that in this case the salaries were fixed at a low figure under the impression that they would be increased by the Commissioners. In the adjoining union of Listowel, however, things are much worse. I have carefully watched the movement in every direction, as given by the press, and I find that Listowel is far lower than the lowest of the rest. This union, which not long since contained eight dispensaries, has now been divided into three monster districts, each district at least twelve miles square; and for each of these large tracts the magnific nt sum of £40 is fixed. No man could perform the duties of any one of these districts with less than a pair of horses. I challenge any of your correspondents to produce an instance equal to this. It is hard to say which party—the doctors or the poor—would suffer most by such a decision. How will the Commissioners act in this case, you shall soon know from

A RATEPAYER.

With respect to the point alluded to in the letter of our Mullingar correspondent, relative to the period of commencing operations under the new system, we have to say that this must depend on the Commissioners and not on the Guardians. As soon as the districts are declared, and the salaries approved of, an "order" will of course be issued, which will declare that "from and after a day named therein, the cost of all medical relief shall be charged on the poor-rate;" and until that order is issued, the present Dispensaries are entitled to the usual support hitherto by law provided for them. With respect to the apprehensions of our other correspondent, lest the Commissioners may have sanctioned the inadequate salaries proposed for the Glin Union, we hope they are premature; and as to the munificent provision made in the Listowel Union, we have no doubt such a proceeding will not be tolerated.

Since the above was written, we have ascertained that the Kilkenny Union has been divided into five districts; salaries not settled; Wexford into six, and salaries of £100 cheerfully voted; Galway into five, with salaries of £120, £90, £90, £50, and £50; Shillelagh into three, with two stations and one Surgeon to each, salaries £100; New Ross into ten, with salaries of £100 to six Surgeons, £80 to two, £60 to one, and £40 to another. The Fermoy Guardians have divided the union into five districts, with two offices in each, to be attended by five Surgeons, with salaries of £75; a payment altogether inadequate for such duty. We have great doubt as to the legality of these sub-divisions of districts, and erection of additional offices or stations. The eighth section of the act says, "The Guardians shall provide a house, building, or room, to be used as a dispensary or office, for the medical officer of *each* such district." It is, however, a point for the consideration of the Commissioners.

ADDRESS TO DR. MACDONNELL, THE MEDICAL POOR-LAW COMMISSIONER.

ADDRESS from the Dispensary Physicians and Surgeons of the County Donegal to John Macdonnell, Esq., M.D., &c., Medical Poor-law Commissioner for Ireland.

DEAR SIR,—We, the Dispensary Physicians and Surgeons of the county of Donegal, beg to tender you our warmest congratulations on your appointment as Medical Poor-law Commissioner for Ireland. The recollection of your past exertions and efficient services in behalf of the profession, your character as a gentleman, and your education as an enlightened physician and surgeon, all conspire to call forth this our united expression of confidence and esteem. With you, a respected and honoured member of our profession, we rejoice to coöperate in carrying out the charitable designs of the legislature, feeling assured that while exercising your official authority with strictness and impartiality, you will ever be mindful of that spirit of moderation and kindness which is certain to secure the efficient working of the new system of dispensary poor-law relief.

Aided by your counsel, the non-medical Commissioners will be better enabled to attach to scientific qualifications and attainments their due weight and importance, and thus your appointment will tend in no small degree to elevate the character and respectability of the medical profession in Ireland. We feel assured that your appointment will receive unanimous approbation; and long may you reflect honour on the office of Medical Poor-law Commissioner for Ireland in health and happiness.

Signed—Henley Sharp, Letterkenny Dispensary and Fever Hospital; Benjamin Johnston, Rathmethon Dispensary and Fever Hospital; Robert Mansfield, Sagert, Donoughmore (or Killygordon) Dispensary; Simon Shiel, Ballyshannon Dispensary, George Frazer Brady, Dungloe, Templecrone, Gweedon, and Burton Part Dispensaries; John Irwin, Moville Dispensary; Henry A. Wallen, Stranorlar Dispensary; William Moorhead, Buncrana Dispensary; William H. Molloy, Millford Dispensary; J. A. Ardagh, Rumullen Dispensary; John Hunter, Fand Dispensary; John Smith, Manor Cunningham Dispensary; John Harvey, St. Johnstown and Castlefarmer Dispensaries; James Burnside, Muff Dispensary; E. C. Swayne, Dunfanaghy Dispensary and Fever Hospital; Andrew J. Hamilton, Bush and Inch Dispensary; Jos. Mulreany, Donegal and Kilmard Dispensaries; George Marshall, Pettigo Dispensary; Richard Coote. Killybegs and Ardara Branch Dispensary; Samuel Johnson, Currigarl Dispensary; James Swan, Inver and Mountcharles Dispensary.

REPLY.

GENTLEMEN,—I need hardly assure you that your kind congratulations on my appointment as Medical Commissioner under the Medical Charities' Act, and expressions of confidence and esteem, conveyed to me in your Address, have afforded me the highest gratification; and I willingly confess that I receive them with pride. With the coöperation which I confidently anticipate from you, and indeed from the Dispensary Physicians and Surgeons of Ireland generally, I am well convinced that the Poor-law Commissioners will find it no difficult task to carry out the charitable intentions of the legislature, as expressed in Sir William Somerville's Act, in such a manner as to make it productive of great benefit to the sick poor, the public, and the medical profession.

I have always thought that the *real* interests of these three parties, in everything relating to the services rendered by our profession to the sick poor at the public expense, are identical. In the services and exertions in favour of my profession, to which you so kindly refer, I have been always guided by that belief as a principle; and I can safely and with perfect truth say, that, in the new position in which I am now placed, I shall ever be governed by the same belief.—I am, gentlemen, your most obedient and obliged servant,

JOHN MACDONNELL.

Dublin, 4, Gardiner's-row, Nov. 29, 1851.

ADDRESSES TO DR. WALSHE OF BALLYNAKILL, IN THE QUEEN'S COUNTY.

ALTHOUGH such expressions of kind feeling as the following may not be so well suited to the wants of the readers of a medical journal, we venture to give insertion to them, satisfied that they are just and sincere tributes of respect and gratitude. Our limits do not permit us to give the names of the subscribers, which are those of gentlemen of the greatest respectability:—

DEAR SIR,—We, the ratepayers and inhabitants of the divisions of Raheen, Colt, Clonkeen and Clash, aware of changes being about to be made in the dispensary districts of Ireland, take this opportunity of returning you our most grateful thanks, for the unremitting care and kind attention which you have bestowed on the sick poor of these divisions

for the last twelve years—years of the most trying nature, when famine and disease swept over the land, and caused fearful havoc amongst our poor. To you, sir, under GOD, do we attribute the comparatively small number of deaths in these localities during the awful periods to which we refer. We always found you prompt in your attendance on the sick poor, wherever and whenever your aid was required. You did not restrict yourself to a mere cold and formal attendance on particular days at the dispensary, but at all times, and in all weather, you visited the hovels of the poor when requisite, acting the part, not alone of an able and successful physician but of a kind and solacing friend, saving the divisions considerable sums, in the shape of poor rates, by restoring the health of those on whose labour alone their families depended for support. We hope and trust that whatever changes may hereafter be made in the dispensary districts of this union, nothing will take place calculated to deprive us of your valuable aid, which an experience of so many years has taught us to estimate more highly than any words we might use could express. Whatever arrangements may be made hereafter, be assured, dear sir, we shall always bear in grateful recollection your kind feelings and able professional assistance, ever cheerfully given to all classes in these localities, but particularly to the poor. In conclusion, we assure you this address is not meant as flattery, neither is it intended to answer a mere purpose. It is, sir, the expression of ardent and sincere feeling on the part of persons alive to the importance of retaining you amongst them as heretofore, and who now in the full sincerity of their hearts return you their most grateful thanks for invaluable services long and efficiently rendered. [Here follow the signatures.]

SIR,—We, the undersigned governors and subscribers to the Ballynakill Dispensary, together with the landholders and ratepayers of the surrounding districts, who have experienced the benefits of the institution, ere our official connexion with it closes (in consequence of the act of parliament recently passed in relation to the medical charities of Ireland, being about to come into operation), deem it an act of duty incumbent on us, and most justly due to you, not to allow the connexion which has so long and so satisfactorily subsisted between us to cease, without giving expression, in language as strong as we can use, to the high opinion entertained by us of your professional skill and respected personal character. For upwards of eighteen years you have been the physician of our dispensary, and looking back on those years, we behold, on your part, the most untiring devotion to the toilsome duties of your office, and on the part of those committed to your care, the most perfect confidence in your skill, as well as gratitude for your humane and kindly attention. Such a retrospect must be to you as it is to us, a source of the most heartfelt satisfaction. Many of the years passed are stamped with peculiar features of suffering to the poor; famine, aggravated by the worst forms of epidemic pestilence, stalked over the land, paralysing almost the energies of all classes of the terror-stricken population of the country. This district was severely visited, yet amid all their complicated wretchedness, we never heard from the poor sufferers even a murmur of complaint against you; on the contrary, they always found you ready at their call, anxious, laborious, and sympathising in your exertions to alleviate their miseries. In our own families, most of us have experienced the happiest results consequent on your professional skill, and so fully are we convinced of your medical capabilities, that we most anxiously look forward to such arrangements under the recent enactment, as will secure to all connected with this locality, and adjoining districts, a continuance of the many advantages they have so long and with so much satisfaction to themselves derived from your professional services.

AN "OPEN" FOR CHEMICAL LECTURERS.

"THE authorities of the University of Sydney and of Sydney College, New South Wales, propose to appoint three professors—viz., a classical professor, who is to be *ex-officio* principal of the college; a mathematical professor, and a professor of chemistry and experimental philosophy, with salaries respectively of £600, £500, and £300 a year, and an additional allowance to each of £100 a year until proper residences can be provided. The salaries of these professors to commence from the day of their landing in the colony. Candidates for these several professorships are to send their letters of application and testimonials addressed to Sir J. F. W. Herschel, Bart., 32, Harley-street, London, on or before December 6, 1851, writing outside their packets 'University College, Sydney.' Printed papers relating to the University of Sydney, and to the University College, Sydney, New South Wales, may be had on application to Mr. W. Ellwood, University Marshal." It will be perceived that to the professorship of chemistry and experimental philosophy, a permanent salary of £300 per annum is assigned. We advise those scientific gentlemen who are inclined to emigrate for the sake of this professorship, to have it clearly understood whether they are or are not expected to provide chemicals and apparatus for the above-mentioned sum. In the event of this liability been thrown upon them, the emoluments will of course be so reduced as to be scarcely worthy of acceptance. If the salary be fixed, exclusive of these necessary expenses, then a certain sum should be allowed for outfit; and it is our opinion that the salary should commence from the day of sailing from this country, or a sufficient sum should be allowed for the expenses of the voyage. With a full understanding on these points, we think that this professorship presents an excellent opening to one who is devoted to science. A good knowledge of mining and metallurgy would be a most desirable addition to the qualifications of the candidate, as there is no doubt that the metallic wealth of New South Wales is as yet but imperfectly known to us, and when properly developed by scientific research, it must necessarily add to the prosperity of the colony and the benefit of the mother country.—*Med. Gaz.*

PROPOSED IMPROVEMENT IN THE STETHOSCOPE.

By B. WILLS RICHARDSON, F.R.C.S.I., of Dublin.

IT may appear presumptuous to come forward in the year 1851 to propose an alteration in the stethoscope, but I am induced to do so, as I think the following addition to the ear-piece has some advantages.

It consists in a small ivory nipple, screwed and cemented into any part of the circumference of a wooden or ivory ear-piece made of the same depth as an ear-piece for an Indian-rubber ring.

The nipple should be covered with a piece of vulcanized Indian-rubber tied round its neck.

With this ear-piece we can percuss with very great accuracy; the nipple resembles the end of the finger, and as, when covered, it will not hurt the finger laid on the chest, it does away with the necessity of a plexiметer.

By having a percussor and stethoscope all in one, there is no occasion to carry a copper hammer, which is a formidable instrument to nervous people; and by getting the ear-piece made heavy or light, it will answer for private practice, or demonstrating any alteration in the clearness of the chest to a large class of pupils.

By taking care that the turner does not make the male screw of the shank of vegetable ivory, there is very little chance of there being a rattle in the instrument.

MEDICAL BENEVOLENT SOCIETY.

THE Treasurer has received the following sums since the last report:—

Dr. Clayton, Athy	£1	1	0
Dr. Maxwell, Moneymore	1	1	0
Dr. Butler, Dublin	1	1	0
Dr. Vesey, Magherafelt	1	1	0
Dr. Brunker, Dundalk	1	0	0
Dr. Bird, Banagher	1	1	0
Dr. Thomas Mitchell, Dublin	1	0	0
Dr. Davis, Outerard	1	0	0
Dr. O'Rourke, Enniscorthy	1	1	0
Dr. Nicholson, Rathdrum	1	0	0
Dr. Morewood, Moneymore	1	1	0
Dr. Lees, Dublin	1	1	0
Dr. Tufnell, do.	1	1	0
Dr. Lynn, Sligo	1	0	0
Dr. Banks, Dublin	1	1	0

M. COLLIS, Treasurer.

APPOINTMENT.—Francis Ffolliott, Esq., F.R.C.S.I., has been appointed Surgeon to the Castlemartyr Dispensary, in the room of Dr. Eames, deceased.

METEOROLOGICAL TABLES.

ROYAL COLLEGE OF SURGEONS, DUBLIN.

Rain, in inches, 0 0: sum of the daily observations taken at nine o'clock.

Meteorological.—The mean temperature of the week was 4 deg. below the mean of the month.

ESSENCE OF BUGS.—In a former number we adverted to the circumstance of a chemist being requested by a homœopathic doctor to prepare for him some tincture of bugs, which he declined to do. We know not to what extent this remedy is in demand among the homœopaths, but have no doubt that a mode of preparing the essence artificially will be found more agreeable and convenient than the ordinary process, which involves the necessity of first catching the animals. The compound to which the term artificial essence of bugs has been applied, is called in scientific language, *oxalate of oxide of amyle.* It is obtained by heating oil of grain with excess of oxalic acid. An oil-like liquid separates, which is amylo-oxalic acid, and which distilled at 500 deg. yields the required product. We have no doubt that when reduced by proper dilution to the state of a homœopathic tincture, it will be found quite as efficacious as the tincture of the animal, of which it possesses the characteristic odour.—*Phar. Jour.*

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT
is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

BROWN'S CANTHARIDINE BLISTERING TISSUE,
PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

Extracts and Editorial Note from the New York Journal of Medicine.

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,
"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,
"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By William Henry Porter, M.D.,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on Venereal Diseases, with additional Notes and Illustrations.

Mr. CHURCHILL, the Publisher of the Medical Times, has the satisfaction of informing the Subscribers to that journal and the Profession generally, that on Saturday, the 3rd of January, 1852, the Medical Gazette will be incorporated with the Medical Times, and the amalgamated journals appear under the title of the

"MEDICAL TIMES AND GAZETTE."

In making this announcement, the Publisher of the united journals has the pleasure to state, that the respected Editor and Publishers of the Medical Gazette have promised their assistance to enable him to give full effect to the union. Arrangements have been made to secure for the

"MEDICAL TIMES AND GAZETTE"

an amount of literary and scientific support, which will enable it to reflect fully the progress of Medical Science, and ensure for it a character, an influence, and a circulation possessed at the present time by no other Medical Periodical.

Published weekly, by John Churchill, 46, *Princes-street, Soho*, price Sevenpence; or Stamped, Eightpence.

Annual subscription, if prepaid, Stamped, £1 10s., and regularly forwarded to all parts of the kingdom.

*** Post-office Orders on the Post-office, No. 1, Coventry-street, to be made payable to Mr. James Lucas, Medical Times and Gazette Office, 46, Princes-street, Soho.

UNIVERSITY OF ST. ANDREW'S.

Notice is hereby given, that the next Examination for the Degree of DOCTOR of MEDICINE will commence on Wednesday, the 5th of May.

Fellows and Members of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin, of the Faculty of Physicians and Surgeons of Glasgow, and Licentiates of the London Apothecaries' Company, are eligible for examination.

Every Candidate is required to communicate by letter with Dr. Day, the Professor of Medicine, fourteen days before the period of examination, and to present himself to the Secretary for registration on or before the 4th of May.

By order of the Senatus Academicus.

James McBean, A.M., Secretary.

St. Andrew's, 5th December, 1851.

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, and CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the Insane, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. Jacob,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

This Establishment, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

MEDICAL, LEGAL, AND GENERAL MUTUAL LIFE ASSURANCE SOCIETY.

TRUSTEES:

James Copland, M.D.
Vere Fane, Esq.
John B. Parry, Esq., Q.C.
The Right Hon. the Master of the Rolls.
J. Russell, Esq., Q.C.

The inhabitants of Dublin and its vicinity are informed that the Agency of the above society has been removed from 25, College-green, to 25, KILDARE-STREET, where every form of assurance may be effected at moderate rates.

G. B. OWENS, M.D., Agent,
25, Kildare-street.

December, 1851.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, Arthur Jacob, M.D., 23, Ely-place, in the City of Dublin.

Mr. TRANT, President of the College, in the chair.

ON ONE OF THE FORMS OF DIARRHŒA, WITH A SUGGESTION FOR THE TREATMENT OF IT, AND ANALOGOUS AFFECTIONS.

By HENRY KENNEDY, A.B., M.B., M.R.I.A.

DIARRHŒA is a disease, or, more correctly, perhaps, a symptom of a disease, which is frequently coming under our notice. Of most medical and surgical diseases, it, at one period or other, forms a complication. It at times is of so serious a character as to add materially to the general mortality; of which the late returns of deaths in London afford a good example. Again, it is sometimes, in the strictest sense of the term, critical; or it may be the precursor of other and more serious diseases—as of dysentery, or the still more formidable disease Asiatic cholera. For these, and other reasons which might be adduced, this single symptom has ever received much attention from practitioners; and the many elaborate articles in our standard works sufficiently attest this. To enter into any general view of the subject would be entirely beside my present purpose, which is merely to direct attention to one of the forms of this affection which appears to me worthy of some more special notice than it has hitherto received.

In reference to my present communication, diarrhœa may be divided into the acute and chronic forms; and it is in the latter that the one about to be spoken of is to be placed. It is essentially a chronic disease, occupying weeks, months, and even years. One of the earliest cases I met had gone on upwards of four years when he first came under my notice. It might be placed under that form of the disease known by authors as the "mucous diarrhœa;" but for reasons to be stated farther on, it ought to be specially distinguished from the more ordinary form.

I have said that it is essentially a chronic disease, and its very onset may be said to be chronic; for it commences so gradually that the patient is often at a loss to state when he first began to complain. Hence it is that few, if any, cases are seen early; the fact being that the patient is often unconscious of his labouring under any special disease. In all the cases I have seen in adults, many weeks had elapsed before they sought advice; whilst one and all stated that they thought the affection of so trifling a character that it might be allowed to wear itself out. In this way the patient will have two to three, or it may be four, evacuations in the twenty-four hours; and as these are most apt to occur at stated intervals, the person's ordinary business is not so much interfered with. In the earlier stages of the complaint, two evacuations are more common than a greater number; and these occur very generally night and morning. The patient, however, is liable to exascerbations, and often without any apparent cause.

The character of the discharges varies somewhat; but speaking generally of them, they are small in quantity, rather inclined to be too fluid, but by no means free of solid matter. They are very apt, likewise, to present a lighter colour than natural; and will occasionally have a tinge of blood on them; but this is not at all constant. In addition to the more common appearance of fæces, there is at times discharged a quantity of mucus, sometimes clear and glairy, and again of a yellowish shade, and very ropy. It is exactly like what may occasionally be seen in children affected with worms, and it is worthy of notice that it is not constantly present: days will elapse and there will not be a sign of it, and then suddenly it will be observed, and in considerable quantity. It is on account of it that the affection I would describe appears to me to be fairly placed under the head "mucous diarrhœa."

Of the exact nature of this affection I am at a loss to speak. I have seen it in constitutions which were contaminated with syphilis; but, on the other hand, I have also met it where there was nothing of the sort. I have also seen it in connexion with Bright's disease; but inasmuch as the great majority of cases recover, if they get proper attention, I cannot think there is any necessary connexion between the two diseases. It is very important, however, if the two exist together, that the point should be fully recognized. On the whole, I am most in-

clined to set down the affection as one of the forms under which the strumous diathesis exhibits itself; whilst I admit, however, that even this opinion is still open to debate, for I have seen instances where the marks of such a constitution could not be detected.

Whatever doubt, however, may exist as to its nature, there is little or none as to the site of the affection; and this is a point—for reasons to be stated farther on—of some consequence to attend to. In all the cases I have seen, the affection was confined to the lower portion of the large intestine; and more particularly to the sigmoid flexure of the colon and the upper portion of the rectum. I do not say that it may not occur elsewhere; very possibly it may, but simply that I have not seen it. Here I have found a portion of the bowel, varying from six to twelve inches, affected with a kind of subacute inflammation, evidenced by congestion and vascularity, in patches, of the mucous membrane; which also gave the idea of being œdematous, and here and there abraded, but scarcely amounting to ulceration. The entire thickness of the intestine was greater than natural, while the neighbouring glands were somewhat enlarged. On the whole, the morbid appearances afforded a very marked contrast to the bowel either above or below the affected part; while at the same time the amount of disease struck me as being comparatively trifling.

The very marked chronic nature of this affection has been already spoken of, and the effects on the general health of the patient are of the same character—that is, weeks and months will pass away, and yet he will be found pursuing his usual avocations. If, however, the effects be slow, they are not the less sure; and sooner or later the general health suffers. The patient finds himself gradually getting weaker, and not so inclined to follow his business as heretofore. There is also some loss of flesh, and he is observed to be looking paler than natural, and finally he becomes confined to bed; some slight pitting about the ankles shows itself, and aphthæ in some part of the mouth; and so he dies, the affection itself not having varied in any important point from what has been already described. It is possible, however, that symptoms of phthisis may supervene towards the last, and so the patient's life be shortened. Nor is this to be wondered at when we recollect that the general health has been undermined for months previously; and so prepared, as it were, to take on any diseased action to which the constitution of the patient may have been predisposed. As far as I have seen, the affection is not one will wear itself out, except in one way—by wearing the patient with it.

The prognosis of this affection may be favourable. The great majority of cases do well, provided they only get fair play. But the slow and insidious character of the complaint is such, that it will happen now and then that it is allowed to go too far, and then all the resources of our art will be in vain, and the patient will die of an affection which there was every human probability could, at an earlier period, have been cured It is scarcely necessary to add, that the earlier the case is seen, it is the easier to cure.

The diagnosis is of some importance; for I believe this affection to be of a specific kind, and that hence it ought to be clearly distinguished from the other forms of diarrhœa; for if not, the treatment is but too apt to be wavering and uncertain. Neither is the site of the disease, already described, to be ever lost sight of. When, then, we meet a case of diarrhœa presenting the symptoms spoken of, and which need not again be gone over, and above all when we find that it has resisted ordinary treatment, continuing in spite of it for weeks and months, we have good grounds for supposing that we have a case of the affection I have been endeavouring to describe to deal with, and we should act accordingly. But this leads me, in the last place, to make a few remarks on the treatment of the affection. Before doing so, however, I may be permitted to observe that, on the many occasions I have had the honour of addressing this Society, I have been always cautious in speaking on the subject of treatment. Nor has this been done without consideration. The actual treatment of disease is, I believe, a part of the profession which is not to be taught either by books or otherwise; in other words, it must be learned for oneself. General principles, indeed, may be taught, and the resources of our art—and they cannot be too numerous—may be learned from others; but their application to the actual treatment of disease is quite another matter, and I again repeat must be learned for oneself. If, indeed, disease presented one uniform aspect—if it occurred under circumstances where there existed an identity of causes, symptoms, and progress—if the human frame were precisely the same in one and all, then we could readily understand how practical medicine could be taught and learned, and its difficulties, comparatively speaking, would vanish. But no one, I presume, can be ignorant that such a state of things neither does nor can be expected to exist. No two cases of disease are precisely the same; no more than is the expression of the human countenance. How, then, is it possible to convey from one to another a knowledge of treatment which will be suitable to a particular case? Every case must be treated on its own merits, and the idea of specifics, or a specific line of treatment, must be given up. These remarks may be illustrated by reference to any disease—it matters not which—of which the treatment is comparatively well known. Thus, if we take a case of pneumonia, peritonitis, or syphilis, and give the most accurate detail of its progress and treatment of which we are capable, does it thence follow that the next case we meet of any of these diseases is to be treated in the same way? Every one, I am sure, will agree with me by answering in the negative; and if this apply to affections which are comparatively well known, how much more strongly does it apply to those which do not run so definite a course, and of which the treatment must necessarily be ever varying? Not that, indeed, we are to wander from the general principles of treatment, but that the details, within this circle, must emanate from ourselves. Did time and the occasion allow of it, I might dwell much longer on this topic, for I believe it to be one of more consequence than might at first sight appear: but I must hurry on.

After what I have just stated, then, a few general remarks on the treatment of the affection described, is all that will be attempted.

It may be stated, of the general run of cases, that more advantage arises from attention to the great principles which regulate health, than from any particular line of treatment, such as might appear to be suited to an affection of the sort. A close inquiry into each case usually discloses the fact that the various functions of life are going on but languidly; and the experience I have had has taught me, that till these are brought into a more efficient state nothing will permanently be of advantage. Hence it is of the most essential consequence that the various secretions be attended to. Small doses of blue pill, administered at twelve hours' interval, will usually be found useful; but of the class of patients commonly affected, many will not bear even small doses. Any opiate preparation combined with the mercury, should, if possible, be avoided. The state of the surface of the body will, of course, receive our special attention. The skin is very apt to be found harsh and dry, and it is of great consequence that it should be brought and kept in the most active state possible. The clothing should be warm; and it has appeared to me that a flannel swathe round the abdomen was of much service. The diet should be plain, and such as the patient knows to be easily digestible; it should include animal as well as vegetable food, but I have not found that any special diet, as, for instance, a milk diet, is followed by any marked benefit.

Of astringents, speaking generally, I have little to say; though they would appear to be a class of medicines well suited to the affection under consideration. When used at the first, many of them appear to be useful, and the

diarrhœa, if not entirely checked, is at least moderated. But this improvement—and the point is one of some moment—is but temporary, and the disease is almost sure to return, and in an aggravated degree. Hence I have found it to be a useful general rule not to order them till the patient be, so to speak, prepared for their use. Then, and then only, can they be given with a prospect of permanent advantage. I may observe of them generally, that, in this particular affection, the purely astringent effect is not at all so marked as in the other forms of diarrhœa. The disease, it will be recollected, is apparently a very mild one, and yet it is by no means uncommon for all the class of astringents to be used with but little, if any, effect. Of those, from the use of which I have seen the most benefit, I would mention the preparations of columbæ; and I think the powder will be found of more use than the other preparations.* The angustura is also a medicine worthy of trial; and, in a late number of the *Lancet*, Mr. Coulson speaks of the tormentilla, used as an injection, being useful.

But it will happen, now and then, that any or all of these means will fail; and the question will then arise, what can farther be done? In answer to this, I would beg to detail briefly the following case, which occurred to me some years back, and which affords a good example of the affection I have been endeavouring to describe:—

Case.—Mr. ——, a gentleman under 40 years of age, of tall stature, pale face, thin person, and very temperate, became my patient some years back. There was gout in his family, while he himself had the signs of the disease in his constitution; still he never had any regular fit of the gout—a state, I need scarcely remark, which is very common to meet with. In the year 1846, he observed that his bowels began to have a tendency to be too free. At first he was affected but once daily, but this was of a more fluid character than natural; then he came to be disturbed twice in the twenty-four hours, and when he took any diet likely to disagree with him, he would have three and even four motions in the day. His general health did not appear to suffer from this in the slightest. In this way, though I was constantly in the habit of meeting him, several months passed over before he thought well of having advice. His health had at last begun to suffer. He was observed to be looking paler than even what was natural to him, and to be losing flesh; neither was he able to follow his avocations with his usual energy, and his sleep was broken and unrefreshing. During a period of about six weeks I directed such means as appeared most likely to afford relief; and at first with some apparent advantage, though subsequently with none. It will be observed that he had no special suffering at all referred to the abdomen. There was no tenesmus whatever, and but very rarely a slight sensation of griping. At this period it was that the evacuations amounted occasionally to four in the twenty-four hours. One day, in conversing with him, he casually mentioned that he now and then had a feeling of heat in the abdomen, and on asking him to what part he referred it, he directed my attention to the left side; in fact to the left iliac region. On the most minute manual examination, however, which I could make through the abdominal walls, nothing could be detected. It then struck me that possibly a speculum might throw some light on the case, and on using it I was able to see that about four inches up the bowel the mucous membrane was much reddened, and seemed to be thicker than natural, and with some signs of abrasion: these appearances too evidently went farther than it was possible for the eye to follow them. This, I confess, was the first time that I got an idea of the exact nature of the affection I had to contend with. A strong solution of nitrate of silver was now applied as high as it was possible to reach; this was repeated at intervals of a week, for five times; and the treatment first used being still enforced, I had the satisfaction at the end of two months, from the time of using the speculum, to see the patient quite recovered. The entire duration of this patient's illness was about ten months.

This case presented a good example of the form of diarrhœa I would describe. He had all the symptoms of the affection in a marked degree. The very chronic nature of the disease, the slowness with which it affected the general health, the not yielding to ordinary treatment, were all characteristic. Of the general treatment adopted, I need not speak; for to that allusion has been already made; but I would direct attention, for a moment, to the local means used. It is quite true that, so far back as May, 1848, my friend Dr. Albert Walsh gave the details of a case which I saw with him, and where the same means were used; but I believe it to be more generally useful than what is supposed, and would therefore bring it forward in a more prominent way than has hitherto been done. Neither would I put it forward as anything new; for every one knows that the application of a caustic to a mucous surface is a well-established principle in surgery. It is the mere application of this principle to affections, in which it has not hitherto been used, to which I would more particularly direct attention. Like other modes of treatment, it is not applicable to every case; and thus it is, speaking of the affection which has been the more immediate subject of this communication, cases will, I know, be met with where the plan will not be required; in fact, they can be cured without it. On the other hand, cases will also occur where no other means that I am acquainted with will save life. The case detailed was a good example of this; for until the caustic was used, the symptoms had persisted most obstinately; in truth, no impression had been made on the disease.

Some may suppose that injections of nitrate of silver would answer every purpose; and to this point I beg particular attention. But it is not so. In the very case detailed they had been used several times, and without effect, previous to the use of the speculum. The explanation would appear to be that the caustic does not come in contact with the diseased part; and even if it did it does not, in my experience, produce, by any means, such beneficial effects, as when applied in the way detailed.

Neither is it in the form of diarrhœa described that this method has alone been found useful. In some cases of chronic dysentery—a much more common disease—it has afforded most valuable aid. It is, I presume, well known that many cases of this affection get into a state where they become neither better nor worse; they remain in *statu quo* as it were; at least to all appearance. Now, in some of these, the caustic has been used as described, with the best effects. In point of fact, the diseased parts require a sudden stimulation, which is effected by the caustic. In the case already spoken of, which I saw with Dr. Walsh, this means was used, and with success; and I must add that it was about as hopeless an instance of the disease as could well be imagined.*

But the question may be rised here—How is it possible that a means which acts so locally can do good in a disease which we know generally occupies so extended a surface? I can only answer this by saying that, from the experience I have had, I have found it most advantageous to apply the caustic in this way, and that I have the best grounds for supposing that its good effects are not confined solely to the parts to which it reaches; but that the healing process being once begun, continues to spread, as it were, till all the ulcerated part is healed. Nor is this without precedent in other parts of the body; for an ulcer on the lower extremity, as an example, may, I know, be made to heal, though caustic be applied solely to one of its borders.

For so far I have only had occasion to use the speculum made by Weiss, together with a bit of common stick, with a portion of lint rolled round the end of it: in this way the caustic may be applied as high as five or probably six inches. I have no doubt, however, that this plan might

* The unstrained decoction, though not by any means an elegant preparation, is well worthy of trial.

* The impression has been forced on my mind, that on too many occasions cases of chronic dysentery have been given up, which might possibly have been saved.

be much improved on in cases where it was an object to apply the caustic still higher; and such cases will frequently be met with. For this purpose I would suggest the use of the long tube, first recommended by Dr. O'Beirne. If this were open at the end, I have no doubt the caustic might be applied in the way detailed, to the height of fifteen or sixteen inches,*—an object, as I believe, of no little importance to carry out in some affections of the colon.

In making use of this means, it need scarcely be added that a common prudence must be exercised, and the avoidance of even the appearance of roughness. In some cases of dysentery at least it would be very possible to injure the coats of the bowels; for the disease appears to render them more than usually soft and lacerable.

In conclusion, it must again be repeated, that this particular means is not suited, nor indeed called for, in all cases of the diseases we have been considering; nor is it to be used, under any circumstances, to the exclusion of other, and what may be called more general treatment.

Dr. Bagot was disposed to think that the subnitrate of bismuth, if employed perseveringly, would be found very serviceable in cases like that detailed by Dr. H. Kennedy. To be useful, however, it must be given in continued doses. He did not wish to condemn the use of opium altogether, as Dr. Kennedy had done in his present paper, because he was of opinion that, combined with the subnitrate of bismuth, it had been hitherto found of great service, and more especially when administered in the form of Dover's powder, which latter, in addition to its sedative and probably its astringent effects also, has an important influence on the skin. If Dr. H. Kennedy had not yet tried the subnitrate of bismuth in continued doses, he (Dr. B.) would strongly recommend him to do so on the first fair opportunity.

Dr. H. Kennedy admitted that the subnitrate of bismuth was a useful remedy; but in cases such as he had described, its employment was seldom attended by any good results—at least such was his own experience. It might be, that owing to the situation of the disease, the medicines underwent some change before they reached the affected part. Whether such was the fact or not, it was plain that the remedies usually resorted to in diarrhœa, had failed to produce their ordinary effects in the peculiar class of cases to which he was calling attention. He had used bismuth in large quantities, and could strongly recommend its use in the diarrhœa of children. In such cases he was in the habit of giving it in milk, and so far as his own experience went, he would say that it was far more useful than any of the medicines usually administered in that complaint. Dover's powder was also a valuable remedy, but was apt to interfere with the secretions. He did not wish to condemn opium altogether, because there was a considerable number of cases where, either to procure rest or alleviate pain, it was of the utmost possible service.

Dr. Fleming wished to offer two or three remarks relative to that portion of Dr. Kennedy's valuable communication which mentioned the occasional occurrence of diarrhœa in connexion with affections of the rectum. Diarrhœa was met with in cases where the ulceration was much nearer to the extremity of the bowel than Dr. Kennedy had described. In many cases, he (Dr. F.) had also employed a speculum, and without presuming to assert that Dr. Kennedy had not seen the condition of the rectum at the distance he had mentioned, he must remark that it could not be very easy, with the aid of any speculum whatever, to see up the rectum distinctly, to a distance of six or seven inches. It would be found, however, that in very many instances, only an exceedingly small amount of ulceration existed in the bowel—an amount so trifling as frequently to escape detection altogether, unless very carefully sought for by the practitioner. This species of ulceration was, he believed, originally pointed out by the late Professor Colles; and if in such cases, the ulceration was sought for, it would usually be found to occupy a spot not more than an inch above the anal extremity of the rectum. In this situation, the disease was within reach, and could be easily treated by the application of caustics. For this purpose he knew nothing that answered better than the nitrate of copper, which could be safely applied with the assistance of a glass speculum, or any other speculum, with a small aperture in its side, like that of Mr. Ferguson. These ulcers in the rectum were occasionally attended with much pain; and it was in consequence of the suddenness with which the evacuations from the rectum took place, and the persistence of the diarrhœa when treated in the ordinary way, that, at length, induced the surgeon to make an examination of the rectum: but these ulcers, in the cases which had fallen under his own observation, were always to be found much nearer to the extremity of the gut than Dr. Kennedy had mentioned—though, at the same time, he did not mean to deny his statement that they were occasionally to be met with higher up. As a general rule, he might say, they were within the reach of the surgeon's finger. The constitutional treatment of the disease was particularly dwelt upon in a practical paper, written by the late Professor Colles, who, he could distinctly recollect, attached very great value to a combination of blue pill, or hydrarg. c. cretæ, with Dover's powder—a combination which, he said, would be found very successful in many instances, if assisted by appropriate local treatment.

Dr. H. Kennedy explained. When he spoke of a distance of six or seven inches, he merely intended it to be understood that he was enabled to convey the caustic so far. He could not of course see to such a distance, but the caustic could be readily applied as high as six or seven inches from the anal extremity of the rectum. With reference to the ulceration of the rectum, he looked on it as a different affection altogether from that described in his communication. In the cases he saw of the disease alluded to by Dr. Fleming, there was always more or less of intense suffering; whereas in the case before them, there was nothing of the kind, and the lower half of the rectum was quite healthy. Besides, there was a marked contrast between the two cases, as regarded the general symptoms. In his case, there was no tenesmus, nor in fact anything calculated to draw attention to the state of the rectum. Before sitting down, he would again repeat that he did not claim the treatment he had proposed as in any respect new. It was simply an application of a well-known principle to a disease which, in his opinion, did not appear to be specially recognized. He might, however, add that, as far as he was aware, caustic had not been generally employed in the way stated in his paper.

Dr. Arthur Mitchell inquired the strength of the decoction of columba used by Dr. Kennedy?

Dr. H. Kennedy replied that a drachm of the sliced root was boiled in eight ounces of water. The dose was one ounce of the unstrained decoction. He was induced not to strain it, on account of the ropy appearance of the liquid, and because it would be more likely to contain the component parts of the columba.

* A bit of any flexible material, such as cane, having a portion of lint tied to the end of it, and this dipped in the caustic solution, might thus be passed through the tube to the affected part.

Treatment of Hæmorrhoids by Operation.—Mr. Skey believes he avoids in operating in hæmorrhoidal cases, the liability of bleeding after the use of the knife alone, by combining the use of the knife and ligature together, which he does in the following manner. He says: the mode I allude to consists in passing a thin copper or iron wire in the form of a loop, made through a double canula around the root of the growth, and strangulating it by drawing the wire tight. This being accomplished, the canula may be retained in this situation for any length of time, from half an hour or more, and the pile may then be removed with the knife or a pair of scissors; and, as it is far easier to arrest bleeding at the commencement than when established, so, should bleeding occur, immediate pressure should be applied by the finger or by pads of lint. Serious hæmorrhage, however, is a rare occurrence.—*Brit. and For. Med. Chir. Rev.*

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Mr. Hodgson, President.

The Society was remarkably crowded this evening, and in consequence of the number of visitors expected to be present, it was arranged that only the Fellows should be admitted into the library until the President had taken his seat. Long before this, however, the library was almost full, most of the hospital physicians and surgeons in the metropolis being present. Commodious as the library is, it could not conveniently contain more than half of those present comfortably; and even with the addition of many extra seats, and the standing room crowded, a great number of gentlemen could not gain admission at all. It was anticipated that "the heads of the profession" would have spoken out on the subject of the operation for the removal of ovarian tumours, but in this respect the large audience was disappointed.

A SUCCESSFUL CASE OF PARTURITION IN A PATIENT WHO HAD PREVIOUSLY UNDERGONE OVARIOTOMY BY A LARGE INCISION. By John Crouch, M.R.C.S.

(Communicated by Samuel Solly, F.R.S.)

The subject of the case was a healthy young woman, aged 26. Two years ago a multilocular ovarian cyst, weighing fourteen pounds, was removed by a long incision. Five weeks after the operation she walked a distance of five miles. During the next winter the catamenia appeared at regular intervals, and her health was good, except that she had an occasional pain in the left groin, and a slight difficulty in micturition, sometimes followed and relieved by a muco-purulent discharge in the urine. In 1850 she married, and on the 9th of October last she was delivered of a male child, after a lingering labour. It had been feared that the expansive powers of the parietes of the abdomen would be impaired by so large a scar passing through their centre; but it was found that the skin dilated naturally, and that the cicatrix itself had increased in length three inches, and in breadth one-sixth of an inch during the period of gestation. Seven weeks after the delivery, the cicatrix in the abdomen had returned to the same dimensions as before the pregnancy—five inches and a half in length, and a quarter of an inch in breadth.

ON THE DIAGNOSIS AND TREATMENT OF OVARIAN DISEASE, WITH THE HISTORY OF ONE HUNDRED AND FIFTY-SIX CASES. By Robert Lee, M.D., F.R.S.

The author commences with a description of the human ovarium, its coats and stroma, and the structure of the Graafian vesicles; and he then notices the condition of the organ before puberty, and the changes which take place at that period, after impregnation, and when the catamenia have ceased. Adhesions of the ovario-Fallopian tubes and uterus are very common. In the unimpregnated state this arises most commonly from inflammation of the peritoneum only; but in puerperal women all the component structures of the ovaries suffer. Thickenings of their coats sometimes are found when there has been apparently no inflammation. Inflammation of the parenchymatous structure terminating in suppuration, in the unimpregnated state, is rare; and the author believes that in those cases where abscesses of the ovaria have burst into the bladder or rectum, they have been the results of scrofulous disease, and not of simple inflammation. Fibrous tumours are sometimes met with in the stroma of the ovaries, which have the same structure as those of the uterus; malignant or cancerous disease also affects the stroma. Both fibrous tumours and malignant diseases are most frequently met with in combination with diseases of the Graafian vesicles, though they may occur without this complication. The greater number of the complex, compound, or multilocular cysts met with in connexion with the ovaria originate in the Graafian vesicles; but it is probable that cystic diseases of a different nature are sometimes set up in the walls of enlarged Graafian vesicles. The author refers to the dissection of an ovarian cyst, published in the last volume of the Transactions, to show that compound cysts are formed independent of each other, and that the smaller cysts do not grow from the inner surface of the larger ones, but are formed in the stroma of the ovaries external to each other. After noticing the varieties observed in the course of ovarian tumours, the author refers to the table of 156 cases of these diseases. In 41, or more than a quarter of the whole, sterility existed, showing a previous unhealthy state of the uterine organs. In 92 the disease occurred between twenty-four and forty-four years of age, while the uterine system was in the most active state. In several cases tapping was performed eight or more times, and in no instance was followed by an immediately fatal result; where death took place after tapping, it was attributable rather to the advanced state of the disease than to the operation. The difficulties of diagnosis in some cases of ovarian tumours are pointed out, as in cases of death of a fœtus. The general symptoms may be the same; and it is only by a careful examination of the lower segment of the uterus internally that in any case it can be positively determined whether the symptoms depend on pregnancy or on some ovarian disease. The soft and thick state of the lips of the os uteri, the shortening of the cervix, the expansion of the body, and the floating of the fœtus, would allow of a positive opinion being formed. "If the uterus be unimpregnated, drawn up, and turned to one side, or pressed forward, backward, or downward, and the cavity of the pelvis be filled more or less with a mass which can be felt occupying the brim—and more or less of the abdominal cavity—hard, or soft, and irregular in some portions, with fluctuation in others, we may conclude that the disease is ovarian." For the diagnosis of ascites as distinguished from ovarian dropsy, the author refers to the description given by Dr. Watson, and adds to this the fact that in ascites the fluctuation is usually more distinct, and that there is an absence of that irregular hardness usually felt in the abdomen when enlarged with ovarian cysts, as also of any unhealthy feeling in the contents of the pelvis. In the latter stages of ovarian disease these diagnostic signs become more obscure. The diagnosis of fibrous tumours of the uterus and ovarian cysts and tumours can, according to the author, be drawn with sufficient accuracy without the use of the uterine sound; and he instances cases in which the employment of this instrument has been productive of evil. Where fibrous tumours are embedded in the walls of the body of the uterus, the whole organ is felt enlarged and heavy, and the cervix is sometimes shortened, as in pregnancy. Attacks of menorrhagia occur, the functions of the bladder and rectum are disturbed, and there are usually pains, with signs of interrupted circulation of blood, in the lower extremities. When cavities filled with fluid exist in the deeper parts of fibrous tumours, the diagnosis is sometimes rendered extremely difficult, if not impossible. With regard to treatment, the author does not put much confidence in any of the usual remedies. Opening and injecting the cysts has generally been followed by fatal consequences, but a cure has sometimes been effected by leaving a small canula or bougie in the opening after tapping; and a case is related, communicated by Mr. Phillips, in which the plan of drawing off only a small quantity of the fluid, and fixing a small elastic gum catheter in the wound for five days, was followed by a gradual diminution of the tumour. In a few cases the long-continued use of iodine and liquor potassæ has produced a diminution of the tumour; but in the majority of instances these remedies have done no good or have done harm. The author prefers treating the disease by the use of saline purgatives and diuretics, light diet, and the avoidance of much exertion, and of every cause likely to irritate the morbid structures. In conclusion, the author refers to an analysis of 162 cases of ovariotomy, published in the last volume of the Transactions. In 60 there was either no ovarian tumour, or the removal was impracticable; 19 of these proved fatal. Of the remaining 102, in which the operation was completed, 42 terminated fatally, and the present condition of the 60 patients who recovered is very imperfectly known.

After a pause, Dr. Aldis said he thought it was a great

pity that there should be no discussion on so important a communication as had just been read to the Society. With respect to the diagnosis between ovarian tumours and ascites, he said, that in the former there was dulness on percussion anteriorly, and resonance laterally; whilst in the latter, the dulness was lateral and the resonance anterior. In one case in which much difficulty of diagnosis was experienced, there was dulness anteriorly, yet no ovarian tumour existed, but after death it was found that the disease was encysted ascites. He related another obscure case, which had occurred in St. George's Hospital, and said, in relation to the operation of ovariotomy, that many persons seemed to entertain extraordinary notions respecting it. Dr. Aldis spoke so low, it was difficult in the crowded state of the room to hear him.

Dr. Meryon regarded the introduction of the uterine sound in cases of uterine disease as an unnecessary interference; and though he had not seen any cases in which the same amount of mischief had followed its use as those alluded to by Dr. Lee, yet he had seen such constitutional irritation result from its employment as was very difficult of reduction.

After a long pause, and while the President and Secretaries were consulting about reading the next paper—

Mr. Streeter rose, and said that he considered the surgical Fellows of the Society, more particularly the surgeons of the metropolitan hospitals, were shrinking from their duty, by not rising and stating the opinions they held respecting the propriety of the performance or non-performance of the operation. Under such circumstances he would make no preface by affecting a modesty which he did not feel, but at once say, that having been present at three operations where ovarian cysts had been removed (in one both ovaries), and knowing that two of the women had recovered, he did not feel justified in remaining silent. He had also witnessed four cases where the tentative incision had been practised with the view of proceeding to complete extirpation, if the nature of the adhesions, so far as discoverable by that incision, should warrant further steps. The diagnostic incision did not, and in consequence three were tapped. The incision healed in all four, and left the sufferers no worse than before. Without at all wishing to dogmatize from this limited experience, he would say that the best conclusion he was able to arrive at was, that as a general rule the operation was not admissible, but there were many, very many, cases of exception to this general rule—cases in which the tentative incision ought to be practised with full preparations for proceeding, and some in which from the knowledge so gained, the operator should proceed for its complete removal. Other surgeons may arrive at opposite and equally conscientious conclusions, but it is not creditable for those who are qualified by reputation and experience to decline the responsibility of advising patients on this operation. Had he risen to disparage the hospital surgeons? Certainly not. Among them were some whom he revered as teachers, many more for whom he felt deep regard from long personal intercourse, and he had expected that those among them who had ever operated, would have risen, and have frankly told the profession what their experience of its performance had added to the former grounds for adopting or refraining from the operation. How otherwise can the difficulties surrounding the diagnosis be lessened? In what other way can the dangers attending the operation be narrowed to their smallest limit? All the causes of failure in the operations already recorded, cannot justly be considered as essentially inherent in its performance. The slipping off of the ligature from the pedicle is not of this character, and other dangers that have attended it might be removed in future operations by an increase of precaution and experience. He regretted that he, a private general practitioner,—one who had been so solemnly proclaimed as only competent "to the ordinary exigencies of surgery,"—should have as it were to lead the way, and compel the discussion of this high and important surgical subject. He had reflected much and anxiously upon ovarian pathology, and this operation, ever since it first became a professional duty to advise a private patient upon the subject. For all the cases he had seen, and most of the knowledge he had acquired of ovariotomy, he was indebted to Dr. Frederick Bird, who had afforded him opportunities which surgeons had twice before declined to give him. With the detail of the reasons which favour its performance he would not trespass on the Society, but only detain them by saying that they were, on the whole, perhaps, best expressed in the *American Journal of Medical Sciences* for 1844, vol. xxxiii., by Dr. John Atlee, in recording his successful case of removal of both ovaries. When all around have abandoned the patient to her fate, the operation remains as her only chance. It is a rock upon which as it is there prettily and feelingly expressed, there "beams a beacon of hope towards which the unfortunate subject of diseased ovarium may turn as from the grave." He should always feel it a duty to give an opinion, and not say to a patient, "Decide for yourself, for I cannot." That was not the way to meet the difficulties of practice, and only tended to bring discredit on the profession. "How cruel it was," said a patient, "to tell me to decide for myself; what did I know about it? He did, and I employed him to tell me whether I ought to have the operation performed or not." He would now allude to one or two points in which the paper of Dr. Lee appeared defective. It afforded no information on the anatomy of the pedicle. The success and difficulty of the removal in many cases depended on the length and vascularity of this part of the tumour. When long, the vessels were for the most part simple, and the ligature was facilitated, but when the vessels were plexiform, the tumour was more sessile, and the space for tying this part much limited. The paper was equally deficient in determining the average duration of life after the occurrence of ovarian disease. Dr. Bright, in the *Guy's Hospital Reports*, states, as the result of his inquiries and observations, that cases which continue "above four years" from the first tapping "bear a small proportion to those which prove fatal before that time." This is a point worthy of confirmation or disproval by accurate statistics. He asked those surgeons—and there were many—who were connected with life assurance offices, to bring the knowledge of the expectation of female life to bear on the consideration of the propriety of this operation in each case. This expectancy was quite calculable. Women, according to Mr. Finlaison's table, at twenty years of age, had an expectation of nearly forty-four years of life (43.99). At forty it was over thirty-one years (31.12). Contrast this expectation with the average duration of life after the operation of tapping, according to Dr. Bright, and consider whether it does not favour rather than forbid the attempt. The sufferer, at twenty years of age, perils four years of wretched life against forty years of existence and renewed powers of social and domestic enjoyment, and so on according to her age. He believed there had been far too much personal feeling mixed up with the purely scientific question of the operation, and that discussions respecting it had been conducted in a spirit that was invariably injurious to the general character of the profession. To those who indulged in these habits of disparaging its members, he would address the words of an eminent living accoucheur, who said that he did not find the members of his profession enjoyed that consideration from the public which he was conscious they deserved; and he always felt it was no part of his duty to lend his aid to lowering them in general estimation. He made these observations because, whilst he conceded to every one the undoubted right of choosing manner and place, he held it to be the duty of all who had performed this operation to place the particulars before the profession. He could not, however, help fearing that the manner in which gentlemen who had brought forward cases of operation were often treated, had, in some degree, contributed to the delay and reluctance evinced on the present as well as former occasions.

Mr. B. Phillips considered that the reluctance of the Fellows to enter upon a discussion that evening was because Dr. Lee had not clearly raised any issue. He had not decidedly advocated one plan of treating ovarian dis-

ease, nor condemned another. It was hardly fair, then, to charge surgeons with indisposition to enter upon the question, because it seemed to be equally felt by physicians. He (Mr. Phillips) was induced to rise, to explain why he was disposed to be silent; besides, as on other occasions, he had taken part in the discussion on ovarian operations, it might seem that he thought the interest of the subject was exhausted. There had been laid before them, by Dr. Lee, two plans of treatment—one palliatory—the other may be called radical; and if he might guess the object of the paper, though this is not stated, it is to induce the Fellows to pronounce that one plan of treatment should be always followed, and that the other should be always discarded. This, no doubt, many persons would think convenient, not only in this, but in other diseases, because it would get rid of all responsibility. All that would be necessary would be to say—a disease being given—the remedy is also given, and there is no occasion for anxious thought. But their profession is not yet so far reduced. Some necessity for thought still exists, and the decision may be wrong or right, even when the disease is known. As to ovarian diseases, taking the results of treatment as laid down by Dr. Lee to be correct, what is the conclusion come to in reference to the duration of life under the palliatory treatment? Nothing definite. But assuming that Dr. Bright's average was correct, and that four years was the average duration of life after the first tapping, this rule cannot be applied to the case before them; for the four years does not apply to every case, but is the result of adding together all the cases that have been under observation, and the time they lived, and then dividing it by the number of persons observed. The average may be four years for each, but of the whole number, one may live a day, one a month, one a year, one twenty years. If we come to apply this information to a case, we cannot tell whether the patient may live only a week, or whether she may live twenty years. He (Mr. Phillips) thought the Fellows of this Society were not prepared to say, with respect to ovarian disease, that they will be satisfied with this palliatory treatment, and will not attempt to do something better for the suffering patient. He himself was not prepared to say that ovariotomy is better; but if Dr. Lee's tables be taken as their guide, it appears that out of 162 cases in which the operation had been attempted, 102 have survived; and that out of ninety-two cases in which the tumour has been removed, fifty-six have survived. He (Mr. Phillips) would not pretend to say that such a result would justify any one in deciding that it should be an accredited operation, though on little better results those for hernia, stone in the bladder, and the ligature of arteries, are so. And in the case of the ligature of the innominata, surgeons have felt themselves justified in doing it a thirteenth time when it had already failed in twelve. Terms of opprobrium have been applied to this operation, but they are not admissible as elements of decision in scientific questions. Mr. Phillips has seen this operation performed ten times; three times the patients died, once the patient survived, though the tumour could not be removed, and six times in succession the tumour was removed, and the patients recovered. What their ultimate fate may be, he of course could not tell; but in the face of those facts he could not say that the operation should never be performed, but he would say that, to justify its performance, there must be the means of pronouncing that the tumour is not so adherent as to prevent its easy removal. Can that be done? He would say, unhesitatingly, No. We cannot tell with certainty, in any case, whether there may not be, practically, insurmountable objections. He knew that it is assumed that the diagnosis is now very refined; but he also knew that those who have paid most attention to the perfection of diagnosis have commenced the operation, and on sixty-one occasions they have not been able to proceed with it. But it is possible that the diagnosis may be improved; it would therefore be arrogant to say that the operation should be absolutely discarded because the diagnosis is not yet perfect, for it is certain that in the case of a simple non-adherent cyst the removal may be successfully practised with a great deal less disturbance to the system than would have been supposed (hear, hear).

Dr. Tanner requested Dr. F. Bird to be good enough to state the result of his experience in ovariotomy to the meeting.

Dr. Frederick Bird said that he had been surprised with the paper just read, and had waited in vain for some new fact in diagnosis or pathology, or at least some sufficient reason for introducing the subject to which it had reference to the notice of the Society; for it was surely unnecessary to describe the elementary anatomy of the ovary, or to occupy time by an imperfect allusion to its morbid changes. That the ovarium was invested by a serous and a fibrous membrane containing stroma and vesicles, were facts associated, in the present instance, with no other novelty than the poverty of their description. The whole paper was so destitute of any addition to the knowledge already possessed of ovarian disease, and its section on diagnosis so singularly poor and deficient, that it rather detracted from, than contributed anything to, the means of investigation. To such cause, he presumed, the difficulty to elicit discussion was to be attributed; and he believed, moreover, that the words of the paper had fallen familiarly on the ears of many besides himself, as it had been already read at the Western Medical Society several weeks ago. It was difficult to select any point in the paper for argument, as the selection lay between the simple enumeration of familiar facts, and the results obtained from statistical tables of which not even a summary was given; for the present tables, like the last presented by the same author, had not been read with the paper, and would probably pass to seclusion until published in the Society's Transactions; and yet Dr. Lee required that the evidence furnished by such tables should be admitted in support of his views (hear, hear). If the present statistical table resembled that presented last year, it would be found fraught with fallacy and error. Before alluding further to the table, he would advert for a moment to that portion of Dr. Lee's essay relating to diagnosis of ovarian tumours; the chief object of which, however, appeared to be that of seeking to cast ridicule upon the use of a very valuable instrument, properly called the uterine sound, but which Dr. Lee had absurdly designated an iron weapon. It was lamentable to observe the spirit of exaggeration which pervaded such statements; it was but a few weeks since, when previously reading his paper at the Western Medical Society, Dr. Lee held in his hand a uterine sound composed of soft metal, which could alone render it a useful instrument, and yet he had now described it as being formed of iron. Unfortunately, Dr. Lee, in speaking of the sound, as of ovariotomy, spoke of that of which, practically, he was profoundly ignorant, or he would not have stated that the application of the sound was to push the womb out of the pelvis, and cause its dislocation: so absurd was it to affirm, that an instrument introduced by so able an authority as Professor Simpson, and extensively employed by obstetricians, was always useless and dangerous. Without its aid, the diagnosis of adhesions between the basic portions of ovarian tumours and the uterus, and the form of the pedicles of such growths, could not be completed; and, rightly employed, it was, in many other points, a valuable addition to practice. If its use were to be rejected in the diagnosis of ovarian tumours, and the investigation of such diseases were to be conducted solely by the aid of the symptoms enumerated by Dr. Lee, errors would without doubt be as frequent as his erroneous statistics sought to make them. To the statements of the author in relation to the operation of excision, similar observations would apply; and no one could read his table of alleged cases of ovariotomy, without regret for the manner in which it was compiled and the faults it contained; that regret, however, was somewhat lightened by an admirable little notice, emanating from the council of the Society, and published in the present volume of the Transactions, containing Dr. Lee's tables, in which the council state, that the Society

does not hold itself in any way responsible for the statements, reasonings, and opinions set forth in the papers. This notice happily precedes Dr. Lee's statistical record of 162 cases of so-called ovariotomy, but which in truth should have been a much smaller number. Among these cases would be found five instances in which no tumour was present, five others in which the tumour was not ovarian, twenty-one cases in which small exploratory incisions only were made, either for the purpose of perfecting the diagnosis or of removing unusually viscid secretions, one case in which a fistulous opening was made after the suggestion of Mr. Bainbrigge of Liverpool, and four cases which have no better testimony than a little idle gossip; there is nothing recorded about them, save that a certain gentleman stated, that in a certain town certain cases had been operated upon by a certain practitioner, and that they had ended fatally. There is no word about the operation, the nature of the tumours, the date, place, or period of their occurrence; and yet Dr. Lee would ask the profession to base opposing arguments upon such vague and worthless evidence. Here, then, was a table of 162 cases, from which thirty-six at least ought to be struck off. In seeking to test truthfully the value of ovariotomy, those examples in which death resulted from a positive accident connected with the operation, as, for example, the imperfect ligature of arteries, ought also to have been excluded. But let the statistics of Dr. Lee be accepted; bad as they were they did but establish the success of the operation. With regard to the propriety of sometimes making exploratory incisions, experience had convinced him of their safety and value in proper cases; but such incisions were generally small,—often not much larger than might be required for paracentesis; they were not cases of ovariotomy, and should not have been classed as such. By small incisions the presence of adhesions could be at once discovered, without passing the hands in amongst the bowels, as Mr. Lawrence had once facetiously stated (laughter), and for the very sufficient reason of the bowels always being out of reach—for in ovarian tumours they lie compressed in the hypochondria. The safety with which such incisions could be made was not remarkable; for when adhesions existed, the peritoneum would be virtually wanting, being so changed in character by the deposition of adventitious membrane, as to be far less prone than in a natural state to inflammatory action. To what the present table, compiled by Dr. Lee, really referred was unknown; but certainly it was not supposed to furnish evidence against ovariotomy; while the paper on ovarian disease to which it was appended was so wanting in new views, so meagre in the narration of facts that were already known, and so deficient in detail, that it would be a disgrace to the labours of a first-year's student (disapprobation).

At the conclusion of Dr. Bird's speech, the time of the Society having expired, it was moved, seconded, and carried unanimously, that the time of the meeting should be prolonged in order to give Dr. Lee an opportunity to reply; hereupon—

Dr. Lee rose, and spoke to the following effect:—Sir, it has just been asserted that my analysis of 162 cases of ovariotomy which have occurred in Great Britain, published in the last volume of the *Medico-Chirurgical Transactions*, "is fraught with errors." It is equally due to the Society and myself, that I should now prove beyond all contradiction, that this charge is wholly unfounded, and that the utmost degree of labour and pains was taken to prevent any error being committed in the construction of this analysis or table, and vitiating the results obtained from it. By referring to the document itself, it will be seen that the first attempt at ovariotomy in Great Britain was made by Mr. Lizars, at Edinburgh, and that when a long incision was carried through the abdominal parietes, there was no ovarian cyst or tumour present to remove, and that the enlargement had been produced by fat and flatulence. Some of the most eminent physicians in Edinburgh had examined the patient before the operation was commenced, and they had no doubt that an ovarian cyst or tumour did exist, and considered it justifiable to attempt the extirpation of the disease. The second case in the analysis occurred likewise to Mr. Lizars, and in this case, one ovarium was removed, and the other, in a diseased state, was left behind, and the patient, I believe, was seen alive some years after by Mr. Lawrence, with a long scar along the front of the belly, and a great tumour within. The third case occurred likewise to Mr. Lizars in 1825, and the incision was made from sternum to pubes, or as a Fellow of the Society has happily expressed it, "from stem to stern." An ovarian tumour was encountered, but it adhered extensively to the pelvis and viscera around, and these connexions could not be destroyed without the employment of great violence. The patient, who might have lived for years, speedily perished. The same year Mr. Lizars operated again, but in this case he encountered a large vascular fibrous tumour of the uterus, which he wisely left untouched. The woman lived twenty-five years after this, with the tumour in her abdomen. She died last year, and when the body was examined after, both ovaria were found perfectly healthy. The account of these cases in the analysis was taken from Mr. Lizars' work, and it is in every circumstance perfectly free from error. The impossibility of establishing the diagnosis of ovarian cysts and tumours was demonstrated thus early in these cases. The next case in the table is from the work of Dr. Gooch; the operator's name is unknown, but when an incision of six inches long had been made, it was found that there was no ovarian disease present to extirpate, and that the enlargement, as in Mr. Lizars' first case, depended wholly upon fat and flatulence. The next two cases occurred to Dr. Granville, who was neither deficient in acumen nor in practical tact. In his first case the ovarian tumour could not be removed. In the second, Dr. Granville found a great fibrous tumour growing from the fundus uteri by a root nearly as thick as the wrist, which he tied and divided. I was not present at the operation, but I saw the tumour in the recent state. This occurred the first year I became permanently fixed in London, and the case made a very deep, lasting, and painful impression on my mind. From that time to this, ovariotomy is a subject which has occupied my serious attention; it has often been forced upon my most earnest consideration by cases in consultation, and I have long felt that the subject was one deeply involving the best interests of humanity, and the honour of English surgery. All the cases that follow in the table have been taken either from published reports, the references to which are given, or from manuscripts in my possession, vouching for the truth of every word stated. Mr. Lane most kindly furnished me with the histories of eleven cases which had come under his own immediate care. It is a striking fact, that in the four last cases, when Mr. Lane had acquired so much experience, the ovarian cysts and tumours could not be removed; the operation was found to be impracticable. This afternoon I received from Mr. Lane an account of the appearances observed after the death of one of these patients, No. 30. This part of the analysis was actually printed from Mr. Lane's manuscripts; there was not a word altered. Dr. Clay, the greatest ovariotomist in this country, on being requested by me to furnish a full report of all his cases, promptly, and in the most liberal and obliging manner, complied with my desire. The analysis contains forty-six cases, and the supplement five, thus communicated by Dr. Clay; and that no error might creep into the account of his cases, the part of the analysis which contained these was sent to him at Manchester, and carefully examined, and then returned for publication. Could greater care have been taken to avoid error, and shield myself from the unfounded imputation now cast, with such reckless disregard to truth, upon my accuracy, in the face of this Society? Not only did Mr. Lane and Dr. Clay come forward nobly and generously, to assist in the inquiry which I had undertaken, with the view of furnishing a body of authentic facts, not of opinion, to enable the profession to determine the real value of ovariotomy in the treatment of ovarian

diseases, but many others—Messrs. Hargraves, Handiside, I. Brown, Paget, &c.—nay, all, followed their example, except two individuals, Mr. Walne and Dr. F. Bird, the latter of whom has appeared here this evening, to throw discredit on my labours by misrepresentations and misstatements. Being personally unacquainted with Mr. Walne, I requested Sir James Eyre to communicate to him my desire for information. Mr. Walne returned an answer, peremptorily refusing to furnish any details of his cases, on the ground that he intended to publish them himself. Afterwards I wrote to him, expressing a hope that he would alter this resolution, and give me the information requisite to render my table complete. I received no answer of any kind to this application. A year and more has since elapsed, but no publication of Mr. Walne's unsuccessful cases has yet taken place, and it is probable the veil now spread over them will never be removed. The analysis contains only a few of Mr. Walne's cases, but surely this cannot be attributed to me as an error. I called upon Dr. F. Bird soon after undertaking this labour, and expressed my wish that he would communicate to me details of all his cases of ovariotomy, successful and unsuccessful. I observed that an opportunity was now presented of contributing to the best interests both of medical science and of humanity. Dr. Bird expressed the utmost readiness to comply, in every particular, with my request. I showed him the table in which the date, age, history of the symptoms, treatment, operators' names, and result, were all to be included; in fact, the table, with a slight modification, which has just been published in the Transactions of this Society. With the propriety of all this he heartily agreed. He praised the plan and the undertaking in the warmest terms, and I had no doubt that in a short time all the desired information from him would be in my possession. But weeks passed away, and nothing came. I called again, and reminded Dr. Bird of his promise. He then renewed the promise he had given, and engaged that within twenty-four hours the necessary information would be transmitted. The twenty-four hours passed away; still nothing came. Another month or more elapsed, and then I consulted a late office-bearer of the Society as to the course I ought to pursue with respect to Dr. Bird. He advised me to abstain from any further application on the subject, as the information, if furnished, would most probably be of no value. Being still most anxious that the analysis should comprehend all the cases of ovariotomy which had occurred in Great Britain, I afterwards wrote a note to him, reminding him of his promises, and begging that he would send me the desired details. In reply to this, the following answer was received:—

"Nov. 2, 1850.

My dear Sir,—When I had the pleasure of seeing you I did not recollect that I was about to publish all my cases of ovariotomy, and that I was in some degree prevented from previously giving their results. I much regret that I have allowed so many days to elapse without writing to you, but hope that the following very brief statement may not be useless from its reaching you at this late period.

I have in twelve cases extirpated large ovarian tumours, several of which were instances in which the dangers of the operation were much enhanced by such complications as peritoneal adhesions, double ovarian disease, absence of pedicle, &c. Of these cases, four died, and eight completely recovered, and were fully restored to health.—Believe me yours sincerely, Frederick Bird.

Dr. Lee."

It was now quite obvious that Dr. Bird was determined not to act like a man actuated by the principles of humanity and science, but rather to play at something like a game of hide-and-seek with me. I was endeavouring to elicit the truth for no other purpose than to arrive at just conclusions upon a subject of the highest importance to the whole profession. This note was put aside as altogether worthless, and no allusion was made to the meagre and defective information it contained in the analysis presented to this Society in 1850. At the discussion which took place on the 12th of November, it must be remembered by many now present, that Mr. Cæsar Hawkins expressed his regret that Dr. Bird had put on record his first successful cases, but had withheld from the profession his unsuccessful cases, a practice which he (Dr. Bird) had strongly reprobated in others. Mr. Hawkins also expressed a hope that Dr. Bird would communicate all these cases, that they might be incorporated in the table, that the profession might have ample and authentic facts to reason upon, and be able to settle the principles of the operation once and for ever. Dr. Bird asserted that he had communicated to me the results of his practice; I replied that he had furnished me with the bare results of the twelve cases in which he had operated, but that this information was so meagre and defective, that I could not, in justice to the completeness of the other cases in the table, add them to this document. Besides, no mention was made in this communication of those cases in which an attempt had been made by him to remove the cyst or tumour without success. Under these circumstances I had left out of the analysis the cases of Dr. Bird altogether. The question was then put to Dr. Bird by Mr. Curling, in how many cases he had commenced the operation of ovariotomy, or had attempted to remove ovarian tumours, in which the operation could not be concluded? The reply was, that he had made exploratory incisions in from forty to fifty cases. This declaration was made in the most deliberate manner, in the presence of nearly 200 Fellows of the Society and visitors. No statement under any circumstances was ever more deliberately and publicly made, but in less than fourteen days Dr. Bird published, in the *Medical Times* and the *Lancet*, a statement purporting to be a complete statement of all his operations, successful and unsuccessful, and all his operations begun but not completed, which he had called exploratory incisions. The Society will hardly believe that the forty or fifty cases of exploratory incisions, or abortive operation of ovariotomy, had dwindled down in eleven days from forty or fifty to eighteen or less than twenty. So treacherous was his memory, or so regardless was he of the facts, that he gave himself this contradiction in the most public manner. What dependence can be placed upon Dr. Bird's most deliberate statement? If there were errors in my table, who, I may now inquire, is responsible for those errors? I repeat that no labour or pain was spared to make that document correct. The secretary and referees all united to make it accurate. I admit that there are cases called cases of ovariotomy in this analysis, where there was no ovarian disease, but in these cases an operation was attempted as for ovariotomy, and therefore they must be included under the same head, and have been so in all other similar tables. Dr. Bird's objection is therefore merely technical; it is an objection without any foundation. Should we not call a case in which the bladder was cut into, but no stone removed, a case of lithotomy? The analysis was constructed with the utmost care, and the charge made here this evening, that it is "fraught with errors,"—"is full of errors,"—is a glaring misrepresentation, and I now denounce and repudiate the accusation. What are the results of these 162 cases of ovariotomy? In sixty there was no ovarian tumour to remove, or the operation was begun and not completed. About one-third of these speedily died. Of the remaining 102, forty-two were destroyed directly by the operation, and sixty are alleged to have recovered. Of the 162 cases, sixty-one died from the immediate effects of the operation, sixty recovered, and forty-two escaped with their lives, most of whom, if the statement made to me be correct, have since died. How many of the sixty who survived are now alive, no man can tell, nor in what state they now exist. It is in vain to seek for information on this head. It has been attempted to institute a comparison between ovariotomy and the great operations of surgery, amputation, hernia, and the ligature of large arteries for aneurism. It is impossible to draw a parallel between these operations and ovariotomy: there is no analogy between them. The great operations in surgery are required because death is impending; if

not performed in compound fracture, in aneurism, and wounded arteries, and strangulated hernia, speedy death is inevitable. Quite the reverse in ovariotomy: this operation has been performed in a multitude of cases—they abound in the table—where life was exposed to no immediate danger, and where the patient might have lived for years if left alone altogether, or the ordinary mode of treatment adopted. When ovariotomy is undertaken, it is impossible in any case to tell whether it be practicable or impracticable. When the surgeon takes up his knife to amputate a limb, it is speedily dissevered from the body; in hernia, the sac in soon reached, and the stricture divided. In sixty out of 162 cases of ovariotomy performed in Great Britain, the operation was begun and could not be completed. The only operation analogous to ovariotomy is the Cæsarian section, which has this marked advantage over ovariotomy—that the knife of the operator is sure to make its way into the cavity of the uterus, and the offending member to be removed. The fœtus has never been found adhering invincibly to the inner surface of the organ. In the Cæsarian section, the patient does not require to be slit open from stem to stern, as is in ovariotomy. I have performed the operation of ovariotomy many times on the dead body—not quite forty, but sufficiently often to make me thoroughly acquainted with the difficulties of the diagnosis and the danger of the operation on the living body. No man can tell, when he begins the operation of ovariotomy, whether it can be completed. It appears to me an act of the greatest cruelty, first to recommend the operation to poor patients suffering under such a disease, and then to throw the responsibility upon the patients, as if they could be aware of the fearful risk to life they are incurring in submitting to the operation. Mr. Streeter has alluded in a feeling manner to this practice. The paper read this evening could not have been read at the Western Medical Society, as confidently asserted, for the best of all reasons, because it was not then written. I have already acquainted the medical secretary with this fact, and I will now explain all the circumstances fully. Being now president of the Western Medical Society, I was called upon to open the present session with an address, or to make some communication on a medical subject for discussion, and I knew of none more important than the Diagnosis and Treatment of Ovarian Diseases. I thought, also, that the paper on this subject, which I was then earnestly engaged in writing for this Society, would be rendered more perfect if I heard the subject discussed by a body of sound practitioners. The histories of the 156 cases of ovarian disease were undoubtedly lying on the table before me, but they were scarcely referred to, and I held in my hand, during the address, only a brief sketch—a skeleton of the facts which formed the communication—to assist my memory. I still continue to think that the uterine sound or poker is a useless and mischievous weapon, and has led to the commission of gross errors in the diagnosis of uterine and ovarian diseases. I know of many such lamentable cases. But if Dr. Bird, who says the paper is barren—though it contains the faithful reports of 156 cases—will really contribute any fact, even of the slightest importance, to improve the diagnosis of ovarian diseases—something more than a set of unmeaning words—I will be most happy to add that fact to the paper, and I have no doubt the council will grant their permission. The same evening, as I was walking home with Dr. Bird, he informed me that he was about to perform ovariotomy on a lady in the country who had consulted me, and whom I had recommended not to submit to the operation. When Dr. Bird made this vaunting statement, the lady had actually been dead some weeks. Neither in this nor in my former paper, have I expressed any opinion on the propriety of having recourse to the operation of ovariotomy. It is, however, well known that I have always been opposed to it. It is right to state that the following paragraph formed the conclusion of my paper when first presented to the Society:—"I am, however, fully aware that other practitioners who have also carefully examined this analysis, have arrived at the conclusion, that there are some cases in which the operation is justifiable and proper. The president of this Society belongs to this number; but he is of opinion that ovariotomy should not be undertaken, in any case, until all remedies have failed, and not unless the disease is producing such injurious effects on vital organs as to endanger life, and which cannot be relieved by any other means. He is likewise of opinion, that in no case whatever should ovariotomy be performed without the full extent of its danger and the uncertainty of its practicability being clearly explained to the patient, and her deliberate assent obtained" (cheers).

The PRESIDENT said that Dr. Lee had very fairly stated his (the President's) views respecting the performance of ovariotomy. He thought it was a proceeding which should not be often resorted to; but that there were cases in which it was justifiable and proper for the surgeon to adopt it.

Dr. F. BIRD begged, before the Society adjourned, to make one observation respecting the case alluded to by Dr. Lee, as having, as it would appear, been operated upon by himself (Dr. F. Bird), and that the lady had since died. He alluded to the case mentioned in the walk home from the Western Medical Society.

Dr. LEE had merely said in reference to that case, that he had advised the lady not to be operated upon. Dr. F. Bird had told him he was going to perform the operation; but at that very moment the lady was actually dead.

DESTRUCTION OF ALMOST THE ENTIRE TEMPORAL BONE.

By Dr. RUSSELL,
Physician to the Birmingham General Dispensary.

MRS. PEYTON, aged 66, a nurse. I visited her as a patient of the BirminghamDispensary at the request of Mr. Figgins on August 10th. She gave me the following history:—

She was attacked with pain in the right ear about six months ago; she attributed it to exposure to very bitter weather, after having been in a hot room; immediately after the pain set in, she found a swelling in front of the ear. About a fortnight afterwards she struck her ear against a bracket; the pain became much increased, and in a day or two "a gathering broke,' discharging profusely through the auditory passage. The pain was relieved temporarily, but soon returned, and with the discharge has continued ever since. The discharge consisted of fetid pus, frequently bloody, or very thin; and occasionally of pure blood, to the extent of a meat-spoonful. About a fortnight before I visited her, a piece of bone "like the mallet bone" came away. The pain has been constant, at times intense, particularly if the discharge ceased for a day or two; she described it as starting from the front of the ear, and radiating over the right side of the head, and across the occipital region, where it was most severe. She often passed hours clasping her head between her hands. On March 30th, two months after the commencement of her complaint, her attention was first called to the existence of some paralysis of the right side of the face.

She has always enjoyed excellent health; has never before had discharge from her ears; though I learned since her death that she had long had a habit of picking her ear with a pin, but without ever complaining of any uneasiness there. Her family is free from consumption, nor is there any trace of syphilitic affection in her history.

At my visit I found the tragus and the cartilage of the auditory passage of the right ear greatly thickened, and quite raw, from the discharge; and immediately in front of the tragus there was a diffused soft swelling, not especially tender, and not fluctuating; there was a draining of fetid sanious pus from the auditory foramen. The right side of the face was partially paralysed; the muscles supplied by the portio dura, and also the buccinator; but the paralysis was not perfect, as the eye could be partially closed voluntarily, and perfectly during sleep, and as food did not collect in the cheek, though the cheek hung loosely, and flapped when she talked, considerably impairing her articulation. The power of masticating was a good deal

impaired; she could only chew sopped food; but from the disease about the root of the zygoma, it was difficult to say whether any share could be referred to impaired power in the muscles of mastication. The right side of the tongue was quite insensible, but the other parts supplied by the sentient branches of the fifth retained perfectly the power of distinguishing impressions. The senses were unaffected, except that of course the right ear was quite insensible to sound. The pupils were natural; there was no sign of paralysis elsewhere; but her arms were rather tremulous, owing to the remains of gilders' palsy, although it is many years since she worked at gilding.

When I first visited her, I found her subject to fits of a kind of maniacal excitement, with great depression of power,—owing, most probably, to want of rest from her constant suffering. My friend Mr. Bindley, who assisted me through the case, having found that a probe passed through the cartilage of the auditory passage, and moved about with much freedom over the neighbourhood of the root of the zygoma, made a free incision upon the point of the instrument; he then felt a considerable extent of exposed bone. Discharge passed freely through the opening during the remainder of her life; and about a fortnight before she died a large piece of bone came away.

It is unnecessary to detail the history of her case further than that the suffering continued with great severity, partially mitigated by large opiates repeated at short intervals, and by extract of belladonna rubbed over the painful regions. The facial paralysis became complete: the buccinator was perfectly palsied, and the conjunctiva of the right eye congested and œdematous. Her intellectual functions were unimpaired, with the exception of occasional nocturnal delirium during the last fortnight. She died October 6th, rather unexpectedly, having been sitting up the day before.

Sectio cadaveris forty hours after death: present, Mr. Bindley, Mr. Carter, Mr. Figgins, and myself. The head alone was examined. On the right side, the integuments and external ear were separated from the bone as far backwards as the mastoid process, and below to the further part of the base of the skull; the inner surface of the interspace was in a state of slough, and emitted a most fetid stench. We found the entire squamous portion of the temporal bone, except a small piece of its upper part, entirely destroyed, and with it a part of the mastoid portion, laying open the mastoid cells; a large irregular opening was thus formed through the side of the skull. The petrous portion of the temporal bone was also destroyed, leaving only a few broken-down fragments, and a mere shell attached to the basilar process: an extensive sloughy cavity was thus formed at the base of the skull, extending almost to the vertebræ, enclosed by the remains of soft parts, covered with flabby, unhealthy granulations. Through the upper part of this cavity, that portion of the facial nerve which is enclosed in the aqueduct of Fallopius passed uninjured, but fully exposed by the total destruction of the bone; this was the only part of the nerve that remained; it terminated at either extremity in a mass of granulation.

The dura mater adhered to the bone nearly to the edge of the large opening; its outer surface, where exposed by the destruction of the bone, was sloughy; it was perforated by an opening, the size of a crown-piece, which corresponded to the commencement of a sloughy sinus through the substance of the brain; at a very small distance from the opening the tissue of the membrane became quite healthy, the orifice of the internal auditory meatus remained, though unsupported by any bone, and without any remains of nerve. The lateral sinus, where lying upon the mastoid portion, was plugged with fibrine of a dirty colour, firmly adherent; it did not contain pus; by this clot the closure of the vessel in the jugular foramen was complete. The eighth pair of nerves entered the jugular foramen as usual, but on the under surface of the skull, the sloughing had removed every trace both of the jugular vein and of the nerves. The carotid artery was healthy; though deprived of its bony sheath, it was enveloped in a dense casing of granulation. The fifth pair of nerves was entire within the skull, but enclosed in a very dense thickened sheath, which must have exerted considerable pressure upon the nerve, and perhaps was one great cause of the intense pain; but here our dissection was incomplete; under the circumstances it was impossible to dissect the nerve after passing into its foramina on the under surface of the skull.

Brain.—From the opening in the dura mater, a sloughy irregular passage led, through the substance of the brain, into the lateral ventricle, which was quite full of sloughy debris, and contained some thin pus in the lowest part of the posterior cornu; the left ventricle was almost as full as the right, apparently from the breaking down of the septum lucidum; the lining membrane of both ventricles was healthy, the sloughy matter being derived from without. In the neighbourhood of the sloughy passage the brain was a good deal softened, and implicated with foul pus; but in all other parts it was healthy. The surface of the right corpus striatum had been infiltrated, but the destructive process had not penetrated to any depth. The arachnoid and pia mater were healthy, except near the sloughing part: there were about two drachms of thin purulent fluid at the base of the brain.

It is impossible to trace the origin of the disease in this curious case; the account given by the patient would certainly lead one to infer that it did not arise within the ear, but probably in the seat of the swelling, which was noticed so soon after pain began: but the history I obtained from her was more meagre than I could wish. The absence of all cerebral symptoms is explained by the fact of the great ganglia of the brain remaining intact, and by the probably slow progress of the disease within the brain: for instances of *acute* softening speedily fatal, after having involved a much smaller amount of cerebral substance, are not rare. The small amount of disturbance following the division by sloughing of the pneumogastric nerve affords a comment on the like result of dividing one nerve by Dr. Reid.—*Med. Gaz.*

REVIEWS AND NOTICES OF BOOKS.

BRADSHAW'S COMPANION TO THE CONTINENT; a Descriptive Handbook to the Chief Places of Resort; with Observations on the Influence of Climate and Travelling. By Edwin Lee, Honorary and Corresponding Member of the Principal Continental Medical Societies, &c. &c. London. 1851. pp. 408.

This is an improved edition of the "Continental Traveller and Invalids' Handbook," published by the author between three and four years ago, with numerous additions, brought out in a more portable form, reduced in price, and changed in name. "The increased facilities for locomotion having rendered distance little more than nominal, a visit to the continent is regarded (the author observes) much in the same light as was formerly a trip to one of our watering places, and there being now uninterrupted communication by steam from all parts of Great Britain to Germany on the one hand, and through France to the Mediterranean sea on the other, almost all the places of resort abroad are of comparatively easy access; so that, as regards valetudinarians more especially, the objection arising from the manifold inconveniences of a long journey on the high roads is, in a great measure, obviated; and travelling, the remedy which from the earliest periods has been recommended in chronic diseases, is generally available."

It has been my chief object, Mr. Lee says, while briefly alluding to the leading features of particular localities, "to dwell more particularly upon those points upon which information is required by invalids and the large class of travellers who seek to combine recreation with restoration to health, as also by the medical profession."

"With regard to climate in particular, it has appeared to

me, from frequently observing the mistakes which occur respecting the choice of localities by patients and practitioners, that the more general diffusion of information which might lead to a more correct appreciation of this remedial agent, as well as of the places frequented on this account, could not fail to be acceptable, the only work on this subject which we possess being that of Sir James Clark. Accordingly, I have taken pains to make this portion of the work as complete as possible, by the addition of general remarks on the influence of climate, and tables of comparative temperature, &c., from the most recent authentic sources."

The countries to which this volume is a guide, are France, Italy, Switzerland, and Germany; and the following extracts from the table of contents will give our readers an idea of the range of subjects embraced by it:—

"*France.*—Boulogne; Paris; French Characteristics; Climate of Paris; Lyons; The Rhone; Marseilles; Climate of Provence; Hyères and its Climate; Causes; Marseilles to Toulouse; Nismes; Pau and its Climate; Eaux Bonnes and Chaudes; Bordeaux and its Climate; Tours; Pyrenian Baths; Bagnères de Luchon; Bagnères de Bigorre; Vale of Argeles; Barèges; St. Sauveur; Gavarnie; Cauterets.

Italy.—Nice and its Climate; The Cornice Road; Genoa and its Climate; Baths of Lucca; Pisa and its Climate; Leghorn; The Maremma; Baths of Monte Catini; Florences its Environs and Climate; Sienna; Rome, its Characteristic, and Environs; Medicine, Malaria, Living, Climate; Pontine Marshes; Naples and the Neapolitans; Sorrento and Castellamara; Ischia and its Mineral Springs; Palermo; Malta and its Climate; Road by St. Germano to Rome; Monte Casino; from Rome to Florence by Perugia; Bologna; Parma; Milan; The Lakes Route to Venice; Venice and its Climate; Pass of Ampezzo; The Simplon; The Haut Valais; Mont Cenis; Turin; Route to Nice by the Col di Tenda; from Geneva to Basle."

The appendix contains remarks upon the influence of climate; especially of the Italian climate, and upon the remedial adaptation of climate; "considerations upon some prevalent predisposing causes of disease, and upon the remedial effects of travelling; notes respecting the mountains of Italy, and a note on Madeira; with meteorological tables."

This volume, we have little doubt, will be as popular as Mr. Lee's other writings; his style is light and agreeable, and the work is calculated to serve the double purpose of a guidebook and an instructive and entertaining companion to the traveller in pursuit either of health or of pleasure.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 17, 1851.

PROCEEDINGS UNDER THE DISPENSARY ACT.

The Boards of Guardians are still busy throughout the country in arranging districts and settling salaries, but with such contrariety of views and interests that no man can with safety predict the final results. It is obvious that the Commissioners must exercise the powers conferred on them by the act, to revise the decisions of the Guardians; and we have no doubt that they will refuse their sanction to proceedings which aim at an evasion rather than an execution of it. Where inadequate salaries have been assigned, or excessive extent of districts declared, they must interfere; and therefore must every union undergo a careful revision. It behoves the Dispensary Surgeon to recollect this, lest he should relax in vigilance under a conviction that the decisions of the Guardians are final and irrevocable. Even since our last, we find in some of the unions symptoms of vacillation, and an inclination to rescind adopted resolutions. In Abbeyleix, in the Queen's County, we find Mr. Stubber giving notice of a motion to rescind the resolution adopted respecting the division into dispensary districts, and elsewhere we find similar difference of opinion. In the Mountmelick Union, which has been divided into eight districts, salaries of £75 have been proposed, but have not yet been agreed upon. Trim Union has been divided into four districts, with two houses, offices, or stations in each; and four Surgeons have been assigned, with salaries of £120 each to two, and £100 to the other two. In Carlow—

Mr. J. Fishbourne inquired what class would be entitled to medical relief, for he knew farmers and gentlemen's servants obtain tickets for dispensaries who could afford to pay for medical assistance?

The Chairman considered that labourers, and that class qualified to demand workhouse relief, were the parties entitled to it in future.

Mr. J. Fishbourne would like to have that question clearly ascertained.

Colonel Bruen considered this act was passed to provide relief for those classes who were not able to procure it, and were proper objects of medical relief. With reference to dispensaries, he hoped the board would not extend the districts so as to render the superintendence on the part of a medical officer impossible, as they could not accomplish their task with railway speed, and the poor should be adequately provided for. The necessary steps should be taken to limit the districts to such an area as to enable the medical officers to discharge their duties efficiently.

Mr. Rochfort said that they had done so on the last board day, and there was no objection to the districts into which they divided the union.

Colonel Bruen—Then if you want the duty well performed at the least expense, give your medical officers a reasonable compensation for their services.

Mr. Browne—Certainly.

Mr. J. Alexander—If you do not separate the Bagnalstown and Leighlin-bridge districts, how is it possible for one medical man to superintend a district which extends from the boundary of the county Kilkenny, in Idrone West, to Mount Leinster?

Mr. J. Fishbourne—No man living could do it.

Colonel Bruen—Unless he possessed the power of flying, or kept two or three horses.

Captain Bath considered, with reference to salaries, that £100 per annum was little enough for all the medical officers. They had paid their doctor £95 yearly for the Fenagh and Myshall district—could they offer him less now with increased duties?

Captain Watson and Mr. John Lecky Watson supported Captain Bath's views.

Mr. A. Fitzmaurice—If you go on in that way you will soon appoint another committee for the reduction of salaries.

Mr. Clayton Browne—It will become necessary, unless we act with prudence.

Mr. J. Fishbourne—And look to the interests of the ratepayers.

Carlow District.—Mr. William R. Fitzmaurice was an advocate for economy, but he considered it no economy not to pay medical men. He read from the *Leinster Express* a list of salaries granted by the Athy Union. The scale was from £120, £100, and £90 a year, according to the extent of their district. He thought that the least sum that could be offered in Carlow was £100.

Mr. Rochfort—I consider Dr. Porter's district both onerous and important, and I propose to give him £100 a year.

Mr. Browne and Mr. Lorenzo Alexander considered this sum as the very least that could be offered to a medical officer having charge of a large and populous town, including an extensive rural district. The motion was agreed to.

Tullow District.—At the suggestion of Mr. Doyne, it was agreed to give £64 yearly to Dr. Burnett, coupled with £56 a year for the fever hospital.

Borris District.—For this district a sum of £70 per annum was given to Dr. Boxwell.

Fennagh and Myshall.—For this district, which was eleven by nine miles in extent, after a long discussion, the salary voted to the doctor was £90.

Ballickmoyler and Newtown.—The salaries proposed for these united districts were £90, £80, and £70 per annum. It was finally fixed at £80 per annum, after a long discussion.

We give this discussion as we find it in the *Leinster Express*, because it touches some points of importance. The class of patients entitled to relief will prove a knotty

point presently. The Castlebar Union has been divided into two districts, with two Surgeons, at salaries of £60 and £50. This will of course be a case for revision by the Commissioners. The Cork Union has been divided into eight districts, with salaries of £68 to seven Surgeons, and £80 to one. In Tralee there was an amusing display of restiveness under taxation. At first the feeling seemed to be to "throw out" the act altogether, and have no dispensaries; but on discovering that this could not be done, the best method of practically evading it became the subject of warm discussion. Mr. HURLY, a well-paid Clerk of the Crown, seems, from the report in the *Tralee Chronicle*, to be one of the advocates of bad payment of "the doctors," and a Mr. O'CONNELL followed in the same direction, so as to effect an economical arrangement providing salaries varying from £40 to £60, which the Commissioners will not of course sanction. In Londonderry, the union has been divided into seven districts, with salaries from £120 to £80. Cashel Union has been divided into four districts, in three the Surgeons to have £75 a year, and in the fourth £60. The Guardians at Urlingford, county Kilkenny, seem to have a sharp discussion before deciding that the union should be divided into four districts, with salaries of £80. In Armagh the union has been divided into seven districts, with salaries of £80, £85, £90, £100, and £120.

THE SHAM SURGICAL DIPLOMA OF TRINITY COLLEGE.

WE find the patentees of this new article in the medical certificate trade are "coming out strong" in the advertising line. Not exactly after the fashion of MOSES or HYAM, of HAYDEN or HOLLOWAY, but according to the most approved practice of paragraph-puffing, upon which booksellers and medicals of a certain caste rely. Amongst the "dodges" of practitioners in this art, a favourite one is to prepare "an article" in Dublin which is transmitted to a London medical journal of easy virtue to be therein inserted as a "Leader," and from this to be copied by a Dublin friendly newspaper, or inserted as an advertisement in disguise in an indifferent one. This dodge has been put in requisition and perpetrated to the letter as we describe; and a fine specimen it is of the ethical principles and literary resources of the school of medical politicians from which it emanates. The happy mixture of exalted love of virtue and justice, with the instinctive leaning to that method which men of law call sharp-practice, marks the authors of the effusion. The pompous exordium which deprecates "unwise dissensions," and all other social evils, is an admirable preface to the coneluding invitation to "buy a diploma." The sentimental philanthropist pathetically complains that

> To impartial minds it cannot but be a source of profound regret that the unwise dissensions and conflicting interests of bygone days should still be evidenced in the corporate and educational distinctions which yet unhappily characterise the professions of medicine and surgery.

What candour, liberality, and sincerity have we here, and how we should admire it, were it not that unfortunately the writer has, from his entrance into our profession till the present hour, never ceased to foment these "dissensions," and to bring into collision these "conflicting interests." It is consoling, however, to find that all this has come to an end, and that unwise dissensions and conflicting interests are extinguished. The "days of such narrow and exclusive views are, however, numbered," and empty benches or alarming reports of the Bursar shall no longer fret the Professors or frighten the Board. The one-faculty-system is, it seems, now to be the rallying cry of Old Trinity, and the tottering steps of decrepid medicine are to be steadied by the support of vigorous surgery; but it appears somewhat startling to see the furious opponent of this same system in 1841 thus extolling it in 1851: circumstances, however, alter cases. Then it was urged that Surgeons were Physicians; now it is that Physicians are Surgeons. Next comes the "cream of the jest." The "Surgical Degree of Trinity College (it is no longer a simple certificate or sham diploma) must take a high position." If we were not sure that "our author" never yet perpetrated a joke, we should suspect him of a banter here, and think he meant to hint that the "surgical degree" might figure in the Park in the "high position" of a paper kite; as it is, although not very unlike another kind of kite, which parties in their need set a-flying, we suspect he only ruminates on the flight of gulls. Be this as it may, the article in question "will doubtless be received *with consideration* by the heads of the medical departments of the public service." Doubtless it will with all due consideration; for to say the truth, we wish our soldiers and sailors some better luck than to fall into the hands of the doctor's customers. But the academic beauties of this precious degree throw its surgical perfections entirely into the shade; "ample provision is made for ensuring a competent general education;" for behold "candidates are required to complete *one year's graduation* in arts." Graduates in Arts and Medicine of Old Trinity think of that! A one year's graduation; a junior freshman degree!!! It has been our lot to witness the decay and prostration of much of which our country was justly proud, but never did we dream of witnessing such a deplorable exhibition as this.

THE APOTHECARIES' HALL *v.* THE DISPENSARY SURGEONS.

WE gather from prevalent rumours that "the gentlemen of the Hall," as the Apothecaries' Company is facetiously called, are, as usual on critical occasions, endeavouring to "kick up a row." They have, we hear, the monstrous audacity to "threaten law" on any Dispensary Surgeon who dispenses medicine in his dispensary, notwithstanding the conclusive decision of the Queen's Bench in the case of NICHOLLS, and notwithstanding the practice time out of mind. It seems they want to compel Surgeons to come to them for "a Diploma" they have been fabricating, which is to serve as a protection against their threats; this Diploma "being neither more nor less than the licence to act as "*journeyman*," provided by the apothecaries' act, and proposed to be granted on a certificate of three years service in a shop, of which service no impertinent questions are to be asked. We warn Surgeons against having anything to do with any such sham licence. The journeyman's licence is only good to enable a young man to assist in an apothecary's shop, and if a protection were required would be of no avail. They say they have got a law opinion in support of their "Diploma," like the Board of Trinity College, but our readers may rely on it that "law opinions" drawn up "to order" are of no value, except to prove the absurdity of legal misconstruction of plain words. Every Surgeon in Ireland is legally authorized to administer medicines to his own patients in or out of dispensaries. He must not "open shop," or even covertly compound the prescriptions of others; that is all the restriction.

CORRESPONDENCE.

INTENTION OF DISPENSARY ACT AS TO FIRST APPOINTMENTS OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—It has been discovered, or at least it is asserted, that under the new dispensary act the Poor-law Commissioners have no power to reappoint the existing medical officers to their several dispensaries. The act (sec. 14) says—"When, on the formation of any district under the provisions of this act, a medical practitioner shall be in possession of a medical office, connected with any dispensary subject to the authority of the said Commissioners," &c. It is alleged that this does not refer to county presentment dispensaries, as they are not, and never were, under the control of the Poor-law Commissioners, nor are they placed under their control by the present act; and if this clause affects any dispensaries, they can only be those six or seven, if any remain, that have been opened under the poor-laws.

Now, this discovery has caused the greatest alarm, for it is obvious that there is not a medical officer in Ireland who, in such case, would not be exposed to the danger of a death's struggle for his position, and for the very existence of himself and his family; and that the whole island from end to end would be, morally, torn in pieces, and its peace and quiet outraged by the excited direful action of religious, political, selfish, and vindictive passions and interests.

To avert this, so great an evil, the Commissioners should suspend the appointment of the medical officers till after the meeting of parliament, when a short bill could be passed without delay, giving to the Commissioners the powers clearly intended by the legislature.—I am your obedient servant,

P. Filius, M.D., &c.

There is nothing in this. It is clear that when the districts are formed the Commissioners are to issue an order, as provided in clauses 6 and 10, which will at once make all dispensaries in the district "subject to the authority of the Commissioners." The intention of the act as to the conveyance of the dispensaries from the present trustees to the new ones is obvious, although there may be some obscurity, especially to the unlearned, in the wording of the clauses which effect it. The Commissioners evidently are empowered to declare the Dispensary Surgeons found in the newly-formed districts, to be the medical officers of the District Dispensaries, and this power they must exercise, however irksome or troublesome it may be: as our correspondent observes, nothing could be conceived more objectionable than a "general election" of Dispensary Surgeons at such a moment as this.

THE PROPOSED SALARIES OF DISPENSARY SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—Let it not be supposed for a moment that the Dispensary Doctors of Ireland are satisfied with the manner in which they are being dealt with by the several Boards of Guardians because they are silent on the subject of the gross wrongs sought to be inflicted on them. They are not; and they would speak, and loudly speak too, were they not quite confident that the Poor-law Commissioners would never lend themselves to the carrying out of such "penny-wise" economy, and by so doing victimize our medical brethren. What does a Commissioner or Inspector do but devote his whole days to the discharge of his duty. Must not a doctor in a remote district devote his days, and perhaps often his nights, to the discharge of *his* duties What leisure time, think you, will a doctor with a district ten miles square have; and look at the difference of payment. I should like to know what the meddling Mr. Senior gets. Look to Macroom, Mill-street, Kanturk, and Newcastle Unions—£50, £60, £70, and £75, the salaries fixed on for medical men—and my firm belief is, that, from the districts allotted, the labour will be so much and so hard, that each man will have to work from morning until night, and, as a matter of course, must keep a horse. Take the support of a horse, of a man to mind it, and house rent, out of £75, and what will it leave? Enough to buy Indian gruel..no more! This will not do. If a man must live in obscurity, let him at least get the means of subsistence. Let the minimum salary be £100, the maximum £130, with allowance for a horse when one is required. Then men will feel pleasure in doing their duty—then, and only then, will the sick poor be efficiently attended. A fraction in the pound added to the poor-rates of a union would greatly increase a doctor's salary—no man would miss it. Leaving the matter in your hands, and confident that there could not be a better advocate, I remain, sir, yours very truly, One of the Aggrieved.

ON THE STRENGTH OF TINCTURE OF OPIUM.

By Dr. Garrod of University College.

As many discrepant statements are to be found in works on materia medica, in various dispensatories, &c., concerning the strength of the tincture of opium of the London Pharmacopœia, it may not be either uninstructive or uninteresting, at least to the medical profession, to have the subject brought under notice and discussion at this Society, in order that they may arrive at some definite conclusion, concerning the strength of a preparation they are in the daily habit of prescribing. If we refer to the London Pharmacopœia of 1836 we find the following directions for making the tincture of opium:—

Take of hard opium powdered, 3 ounces
Proof spirit, 2 pints
Macerate for fourteen days, and strain.

In the Pharmacopœia of 1851 we are ordered to—

Take of opium powdered, 3 ounces
Proof spirit, 2 pints
Macerate for seven days, press out, and strain.

The only difference in the directions being that powdered *hard* opium, and digestion for *fourteen* days, are ordered in the one case, and simply powdered opium and seven days digestion in the other. If we look at the authorized edition of the Pharmacopœia by Mr. Phillips of 1836 (and also at the present edition), we find stated, that the preparation has a deep brownish red colour, possesses the peculiar odour and taste of opium, has sp. gr. 0.952, and about 19 minims contain 1 grain of opium, which is said to be proved by the following data: 1st, by evaporating the tincture, and finding the amount of solid extract left; 2nd, by ascertaining the quantity of opium remaining undissolved. The conclusion at which Mr. Phillips arrived, viz., that 1 grain of opium was contained in 19 minims of the Pharmacopœia tincture, has been copied into most English works on materia medica, and most medical men have been and are still in the habit of prescribing the tincture considering it to be of the *above* strength. Were Mr. Phillips's conclusions correct?

With regard to the amount of solid extract left on evaporation of the tincture, it appears from the experiments of Mr. Allchin, which are also confirmed by those which I have myself made, that 19 minims yield about 1 grain of extract; but in these cases the Turkey opium of commerce must be first exsiccated; and the tinctures of commerce yield quantities varying from 1 in 19 to 1 in 28 minims of the tincture. Tincture of opium made with Turkey opium in small masses not previously dried, fl. ʒj. gave on drying 2.7 of solid residue, or 1 grain in about 22.2 minims. Tincture of opium made with good Turkey opium, previously dried and reduced to powder (Pharmacopœia directions) fl. ʒj. gave on drying—three experiments—3.1, or 1 grain of residue in 19.3 minims.

If made with opium capable of being reduced to a state of powder, the average quantity of extract would be about 1 grain in 20 minims; this proportion would indicate that one third of the solid ingredient (opium) is left undissolved, which was found by Mr. Phillips to be the case. I believe all good specimens of Turkey opium yield about this amount of residue. An experiment made within the last week at Mr. Bell's establishment gave this

result. If then the strength of tincture of opium be considered to be that indicated by Mr. Phillips, we must assume that the undissolved portion possesses the same therapeutic effects as the dissolved portion. Is this correct?

It has been stated by some that morphia can be extracted from the residuum, and in Dr. Pereira's Materia Medica, we find the following observations:—"Proof spirit dissolves the same constituents as water does, but it takes up a larger proportion of *narcotine*, *resin*, *oil*. I have repeatedly prepared morphia from the insoluble residue left behind in the preparation of the tincture." Again, in Dr. Thomson's Dispensatory it is stated that Mr. Brande finds that the whole of the morphia is not taken up; but is found in no inconsiderable quantity in the filter. We suspect occasionally *narcotine* has been taken for *morphia*, and in the cases where *morphia* has really been found, unless the residue had been previously washed, an error may have arisen from the alkaloid being contained in the tincture of opium adhering to the dregs, and not from any contained in the residue itself. I have recently endeavoured to ascertain the true state of the case, and chiefly by means of a therapeutic inquiry into the strength of the residuum. The residue of tincture of opium prepared in the ordinary way at University College Hospital, was taken for experiment; it was first washed with a little cold water to remove any adhering tincture, and afterwards dried in a water-bath. By digestion with ether, it was found to yield abundance of *narcotine*, and was also found to contain *meconic acid* sufficient to strike a claret colour with the persalts of iron; but at the same time nitric acid gave no evidence of the presence of *morphia*. It was found also by experiment that proof spirit at the ordinary temperature dissolved but a very small portion of narcotine; the bulk of the narcotine therefore remains in the residuum from the tincture of opium, perhaps united with meconic acid; for when treated with water acidulated with acetic acid, both *narcotine* and *meconic* acid were dissolved.

A portion of the residue was given internally; *one grain* to a healthy adult produced no effect; *two grains* were given with no result; the dose was then successively increased to *four grains*, then to *six grains*, afterwards to *thirteen*, and lastly to *thirty grains*, without causing the slightest effect on the individuals to whom it was administered; the only limitation to the quantity given being the unpleasantness of taking so large an amount of so bulky a matter. It appears, therefore, that the residue is, to all intents and purposes, inert.

From these experiments, it is evident that even *should* traces of *morphia* be contained in the dregs, still the quantity must be such (when the tincture is prepared according to the London Pharmacopœia) as to make no appreciable diminution of the strength of the preparation, and that the tinctura opii contains the active matter of the whole of the drug used in its formation, and therefore about 12 minims of tincture of opium possesses all the activity of 1 grain of crude opium, assuming that it loses only 12 per cent. in the drying. If dry opium is taken for comparison, 1 grain is contained in about 13½ minims; and therefore *one* fluid drachm of tinctura opii contains about 5 grains of the drug, or 4½ grains (according as it is compared with the dry or moist opium), in place of 3 grains; or 1 fluid ounce contains 40 or 36 grains in place of 24 grains usually assumed to be contained in it; a difference of strength of the highest importance when we consider the highly poisonous and powerful therapeutic action of the drug.

In the Edinburgh preparation the amount of tincture containing a grain of opium in about 13½ minims, for the opium is ordered in the same proportion but not previously reduced to powder or dried. In the Dublin preparation the opium is ordered to be coarsely powdered, but avoirdupois weight is used in place of apothecaries, which makes the strength of the tincture such that 12.75 minims contain *one* grain.

The error as to the strength of the tincture of opium, which is found in so many works, has been recently commented on. Thus Dr. Christison objects to Mr. Phillips's statements; Dr. Royle also alludes to it, and so does Mr. Squire, in his recent work on the Pharmacopœias; and even those writers who have copied the statement must have done so without much thought on the subject, as they have calculated the strength of other preparations of opium, as that of the tinctura opii ammoniata, tinctura camphoræ composita, assuming that all the active properties of the opium used in the preparation had been taken up by the menstrua. And this is the case even with Mr. Phillips himself, in the case of the compound tincture of camphor, when he states that *nearly two* grains of opium are contained in the ounce, the Pharmacopœia proportions of opium being 1.6 grains only.

I have brought the question before the Society more for the purpose of eliciting the opinions of the members on the point, than with the idea of bringing forward much that is novel on the subject; if the conclusion to which we have arrived—namely, that 12 minims of tincture of opium contain all the medical properties of 1 grain of the crude drug, I think it very important that the members of the medical profession should be made fully aware of the delusion under which they have laboured for so many years with regard to the strength of this important preparation. —*Phar. Jour.*

A LAWYER'S OPINION OE MEDICAL MORALITY.

According to the *Morning Chronicle* of the 6th inst., whilst the Lord Chancellor was hearing a lunacy case, the previous day, he is reported to have uttered the following observation:—"When a medical gentleman, with a large fee, was sent to visit a patient, his report invariably sustained, to a great extent, the view taken by the party employing him." Disregarding altogether the animus which apparently dictated such language in a court of justice, we must dissent *in toto* from its application to medical practitioners; and would respectfully assert, that the profession are quite as honest in giving their opinions as any barrister consulted upon a point of law by a solicitor. Lord Truro, having once been an attorney, knows better than we could tell his lordship, that should the counsel decide against a client's right of action, that recommendation is never communicated to the opposite party; nor are adverse witnesses ever called whose evidence might invalidate the plea brought forward. The same proceeding is always followed respecting medical statements and evidence. If unfavourable to the persons employing the professional gentleman consulted, nothing is said thereon; so that the court is never informed unless in support of the case then advocated. Therefore, to believe that medical men always decide in favour of the individual who pays them, is fully as erroneous as it would be for a Lord Chief Justice to observe, during the trial of a case before him—"It is very singular, when counsel with a large fee comes to plead in this court, his oration invariably sustains, to a great extent, the views taken by the party employing him!" How the common law bar would grin at such an effusion may be easily conceived. Nor would learned wigs be less astonished were one of the legal fraternity to quote precedents against his own client, or argue in favour of the opposite one. Another dictum recently expressed also deserves animadversion, when it was said that fifty guineas given to Dr. Winslow for visiting a patient in Yorkshire seemed large. On the contrary, we think the amount was less than half what it ought to have been, considering the time employed, and the responsibility that physician thereby incurred. Instead of criticising medical practitioners, we would advise all judges to condemn barristers who take large fees from attorneys to appear in court when particular cases are called, but cannot be found at the critical moment. This would be much better reform than grudging the honorarium of a medical man for mental and bodily labour actually performed. With all deference towards the venerable judges of England, we sincerely believe it is injudicious and misplaced, for an occupant of the judicial bench to indulge in tirades which may disparage either his own or any of the other learned professions in public estimation.—*Lancet.*

Dr. Kingsley of Roscrea, was entertained at dinner on Thursday last, by his professional friends, at Anderson's hotel, in this city.

DEATH OF PRIESSNITZ.—Priessnitz, the celebrated founder of hydropathy, died at Graefenberg on the 26th of November, at the age of 52. In the morning of that day Priessnitz was up and stirring at an early hour, but complained of the cold, and had wood brought in to make a large fire. His friends had for some time believed him to be suffering from dropsy of the chest, and at their earnest entreaty he consented to take a little medicine, exclaiming all the while, "It is of no use." He would see no physician, but remained to the last true to his profession. About four o'clock in the afternoon of the 26th he asked to be carried to bed, and upon being laid down he expired.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D.,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

MEDICAL, LEGAL, AND GENERAL MUTUAL LIFE ASSURANCE SOCIETY.

TRUSTEES:

JAMES COPLAND, M.D.
VERE FANE, Esq.
JOHN B. PARRY, Esq., Q.C.
The Right Hon. the MASTER of the ROLLS.
J. RUSSELL, Esq., Q.C.

The inhabitants of Dublin and its vicinity are informed that the Agency of the above society has been removed from 25, College-green, to 25, KILDARE-STREET, where every form of assurance may be effected at moderate rates.

G. B. OWENS, M.D., Agent,

CASES OF PULMONARY DISEASE.

By Edmund Sharkey, A.B., M.B., T.C.D., of Ballinasloe.

(Continued from p. 292.)

Having, in the number of the Press of November 5th, directed attention to one class of cases of incipient phthisis in which iodine seemed to me entitled to a certain amount of confidence, I should have noticed in connexion with it, a remedy which has obtained a very considerable degree of favour in the treatment of all forms of the disease. I allude to cod-liver oil. I would now, however, observe, that I cannot but think that *one* at least of the most active principles contained in it is iodine. According to Mr. Donovan's able investigations, the golden-coloured variety of the oil is that alone on which reliance can be placed, and this golden colour is derivable from two sources—viz., the contained iodine and the biliary secretion of the animal; and it seems more consistent with known facts to attribute the efficacy of the medicine to the former than the latter.

I alluded to another form of incipient phthisis distinguished from the first by a greater amount of general, and especially vascular excitement, most probably inflammatory, in which, if blood be drawn from a vein, it generally presents the excess of fibrine corresponding with that condition of the system. To this form the iodine treatment is not suited, but that by mercury has been followed by marked and speedy success. Cases of this kind have been recorded by Dr. Munk in the *London Medical Gazette* of 1840–41, and the following is one which fell under my own observation, and is strongly confirmatory of his views. I may add, that the practice has been found occasionally successful also by Drs. Graves, Stokes, Corrigan, and Sir H. Marsh.

Case 7.—Jersey, August, 1843.—A young woman, aged 27, has had hæmoptysis to a great extent for some months past, said to have commenced after suppression of the menses, in consequence of exposure to cold during their flow; she has hacking cough, with expectoration of pure blood; dyspnœa great, amounting on one occasion to orthopnœa, with an excited pulse, emaciation, and profuse night-sweats. Was bled to lb. i. Blood intensely buffed and cupped; considerable relief followed. She was treated with small doses of ant. tart., in conjunction with nit. potass. and camph., and her chest was blistered. The stethoscope detected no very positive signs, neither was any dulness found in any situation on percussion. Her progress towards recovery was very slow under these means. A diarrhœa came on, and on giving a few grains of hyd. c. cretæ for its relief, ptyalism ensued, which suddenly removed all the symptoms, and she is now quite well. I should add that she was pregnant at the time, but concealed the fact.

In this hæmoptysical variety of incipient phthisis, when, after venesection carried to as great an extent as seems advisable under the circumstances, I have found a combination of camphor and nitrate of potash, with the addition sometimes of minute doses of ant. tart., very effectual in producing such a reduction of the pulse as the bleeding alone had failed to accomplish. I have generally given it in the proportion of gr. v. camphor to gr. xv. nitrate of potash, twice or thrice a day.

Case 8.—*Confirmed Phthisis.*

Allihies, Berehaven, county Cork, February 12, 1836.—Richard Trewhela, aged 16, a Cornish lad, a blacksmith, of a strumous family, has had a cough for some time, which has been alleviated at intervals by medical treatment and change of air. When examined by me a year ago, he presented suspicious physical signs of phthisis at the top of the left lung. There is now dulness on percussion at the top of the left lung, with large mucous râle, bronchial respiration, and resonance both of voice and cough. His symptoms are, irregular rigors, loss of strength, and emaciation, palpitation, strong action of heart, quick pulse, expectoration occasionally bloody, anorexia. The treatment prescribed was the mucilaginous mixture, containing ipecacuanha, camphorated tincture of opium, and tincture of digitalis (a drachm to fourteen ounces), Griffith's pill morning and evening, and flannel to be worn next to the skin. On the 24th there was great improvement, especially of the appetite.

March 7th. Has retrograded in consequence of imprudence, as he has not ceased to work in the forge, and consequently suffers from vicissitudes of temperature.

14th. Feverish attack, with diarrhœa, but no increase of cough; epistaxis to the amount of four or five ounces; pain in the right side and shoulder.

15th. Diarrhœa relieved; violence of cough has caused a return of the epistaxis. He was ordered

℞ Mass. pil. hyd., ext. hyos., pulv. ipecac. āā. gr. xii.
Pulv. opii gr. vi. Mft. massa in pil. xii. dividenda sumat. i. mane et nocte.

A small blister to be applied under the left clavicle.

21st. Blister not applied; evident increase in the physical signs of a cavity; diarrhœa continues.

Sumat. plumb. acet. gr. ss.
Opii gr. 1.6 bis in die.
℞ Fol. uvæ ursi, ʒi.
Aquæ ʒxii. coque ad ʒviii. Dein adde
Tinct. digital. ʒi.
Syrupi q. s. Sumat. ʒi. ter in die.

This treatment, aided by a blister under left clavicle, produced great mitigation of pectoral symptoms. For the relief of the diarrhœa, the lead and opium was continued, and the tincture of digitalis omitted, Lugol's solution of iodine being substituted in the proportion of ʒii. of solution to ʒxiv. of the decoction.

28th. Passed a large worm; cough becoming more severe; pulse 120; cough relieved, and sleep procured by ʒi., ii. tinct. opii camph. This treatment was persevered in, with the irritation of tartar emetic ointment in left subclavicular region, till the 19th of May, when the report is as follows:—"Has improved in general health; has no hectic paroxysms; appetite exceedingly good; pulse 120, with the same physical signs in chest." And on June 12th, "has gained considerable strength; runs about, even up steep hills; is recovering his complexion; an abscess has appeared at the verge of the anus, opened, and discharged profusely."

August 5th. Still continues well; the abscess has healed without treatment, and another is pointing at the other side. All the physical signs of a cavity still remain, but the secretion from it is very trifling, as is also the cough. All the functions improved; pulse still 120; no hectic.

During a period of nearly two years—viz., until June, 1838, this boy enjoyed comparatively good health, being able to pursue his laborious trade, and even join in the fatiguing amusements of his companions—walking, running, and shooting in the mountains. On the 10th of June, 1838, he got an increase of cough, with anasarca of the face, legs, and body generally, with white tongue, and deep yellow urine, but not scanty, with occasional headache and epistaxis, for which he took pills containing pil. hydrarg., pulv. scill., and pulv. digital., with a mixture containing carb. potass., and subsequently saline purgatives and tincture of digitalis. The dropsical symptoms were removed, but returned in the following October, and were similarly treated. I should have mentioned that all through his illness there was a tendency to diarrhœa. This diarrhœa had become more troublesome in March, 1839, and was accompanied by a fistula in ano, which discharged copiously. He was also attacked by painful erythema of arms and legs, with some fever and great œdema of the face, and scanty urine. The cough was trifling, but there was great palpitation on taking exercise. It is needless to pursue this case further than to say, that he was run down by the diarrhœa, and sunk on the 24th. On applying the stethoscope under the right clavicle, cavernous respiration alone was heard without any râle, showing that the cavity had ceased to secrete.

From a review of this case, I think I am warranted in saying that under more favourable circumstances it would have formed one of the so called "cured cases of consumption." There had been unmistakable evidences of an extensive cavity, with corresponding constitutional sympathy, and we have seen that these hectic symptoms subsided, and that the boy (who was most imprudent and uncontrollable) abstained from none of the violent exertions incident to his age and occupation, and which involved great exertion of the chest, and great and sudden alternations of high and low temperature, checked perspirations, &c. It is most probable that had he been in a rank which would have enabled him to seek a more friendly climate, his life might have been prolonged with comfort to an advanced age.

In confirmation of this, I may relate a remarkable case which came under my care during the six years of my residence in Jersey.

Case 9.—Chronic Phthisis—Cavity Cicatrized.

A lady who had, at the age of 20, been attacked by hæmoptysis, and had been pronounced, by medical authority of the highest respectability, phthisical, had, from that time up to the period when she came under my care, been subject to chronic cough and copious expectoration, which was periodically increased to such an amount and accompanied by such debility as to give rise to an idea that abscesses burst from time to time. The stethoscope, however, gave no countenance to this opinion, detecting merely constant dulness, very marked under one clavicle, with cavernous respiration and the corresponding vocal phenomena, and occasional gargouillement. When these periodical attacks subsided, she recovered her usual strength, appetite, and spirits, and was capable of a good deal of exertion until the next. She continued up to the last year of her life to enjoy, with the above exception, an average state of health, and died within the last year at the age of 68.

I have no doubt that this was a case in which a cavity or cavities had existed, and subsequently became lined by a protective membrane and cicatrized; that it was, in fact, a case of what is usually termed "consumption cured;" and that the periodical increase of secretion was an effort of Nature, and salutary.

The following would appear to have been somewhat of the same character:—

St. Helier's, Jersey, June 28, 1847.—*Case* 10.—A woman, aged 45, had an attack of pneumonia or pleuropneumonia of right side, accompanied by complete dulness. She was relieved by mercury, pushed to salivation, blisters, and tartar emetic. Three days ago she presented herself, complaining of great and constant pain of right side, for which she took pil. hydrarg. and ext. hyos. This morning came, saying that she had spat up great quantities of fetid "corruption," with relief of pain, but great consequent debility.

July 1st. On examination with the stethoscope, I found pectoriloquy in the base of posterior right lung. She has night-sweats, copious expectoration, and great debility.

℞ Mass. pil. Griff. ʒi.
Quin. s. gr. vi. M. et in pil. xv. divide.
Sumat. i. ter in die.

March 3, 1848.—I saw her to-day; she is completely free from complaint, with the exception of some pain of right shoulder and subclavicular region. Catamenia have become regular. This case may, however, be considered doubtful, as it may have been possibly one of pulmonic or hepatic abscess.

Case 11.—*Phthisis with Cavity.*

Jersey, October 7, 1845.—A married woman, aged 32, has been for two years affected with difficult breathing and cough. After the birth of a child two months ago, she was attacked by an acute aggravation of her complaint, which assumed the character of well-marked phthisis, with a cavity under the left clavicle. She has expectorated an immense quantity of purulent matter. The hand placed under left clavicle perceived a distinct sensation of gurgling. Within a few days the expectoration has nearly ceased, as also the cough and gargouillement under the clavicle, while face, abdomen, and extremities have swelled, and this symptom is accompanied by a diminution of the urinary secretion. Bowels are regular, and appetite has improved.

℞ Infus. armoraciæ c. ʒviii.; potass. nit. ʒii.
Sumat. cochl. ii. mag. ter in die.

13th. Has been attacked by severe pain of left side, for which a blister was applied with relief; strength improved.

℞ Ext. belladon. gr. ⅛.
Conii gr. ss.
Hyos. gr. i.
Lactucarii gr. ii.
Pulv. ipecac. gr. ½.
Ft. pilula ter die sumenda.
Empl. ext. belladonnæ lateri sinistro.

20th. Pain of side relieved by empl. belladonnæ; has heat of skin, followed by profuse perspirations; the dropsical swellings have subsided.

Nov. 8th. The cough has nearly ceased, and all the functions are tolerably regular, but she suffers from profuse night perspirations; appetite diminished.

℞ Tr. hyoscyami, ʒii.
Acid. sulph. d. ʒi.
Aquæ ʒviii. M. st. ʒi. ter.

She subsequently went to the seaside, and is said to have perfectly recovered, and when I last saw her she had acquired a good deal of flesh.

This case presents the occurrence of a phenomenon frequently observed—namely, the vicarious appearance of anasarca in the sudden subsidence of a copious purulent discharge.

A NEW TEST FOR MERCURY.

The following seems to be a novel and hitherto undescribed method of detecting the salts of mercury either in substance or solution:—

If a strong solution of iodide of potassium be added to a minute portion of any of the salts of mercury placed on a clean bright plate of copper, the mercury is immediately deposited in the metallic state, appearing as a silvery stain on the copper, which cannot be mistaken, as no other metal is deposited by the same means.

By this method corrosive sublimate may be detected in a drop of a solution unaffected either by caustic potash or iodide of potassium in a mixture of calomel and sugar in the proportion of one grain to two hundred. A distinct metallic stain will be obtained with one grain, which of course contains 1–200th of a grain of calomel; in like manner 1–400th of a grain of peroxide of mercury may be detected, although the mixture with sugar is not in the least coloured by it.

With the preparations of mercury in the undiluted state, this process acts with remarkable accuracy, the smallest possible quantity of calomel or peroxide of mercury, such as would almost require a magnifying lens to perceive, placed on copper and treated with iodide of potassium, will give a distinct metallic stain.

The advantages of this test may be briefly stated as follows:—1st. It is a delicate test, inferior only to chloride of zinc and the galvanic test of zinc and gold. 2nd. It is easy of application. 3rd. It requires a very small portion of the substance to be examined—a matter of no small import. 4th. Acting on the insoluble as well as the soluble salts, it obviates the intermediate process of solution. 5th. When it acts its indications are decisive.

As to its disadvantages, the only one which seems tenable is, that although it acts on minute portions, still that must be in a concentrated condition. For instance, though we may detect the 1–1000th of a grain of corrosive sublimate in a drop of water, we cannot detect it in a drachm; but this may of course be remedied by evaporation.

Now, with regard to the theory of this process, the following seems most satisfactory, that the iodide of potassium forms a soluble and easily decomposed salt with the various salts of mercury: that is, an iodide soluble in excess of the iodide of potassium.

The foregoing is the substance of a paper read by Mr. Arthur Morgan, City of Dublin Hospital, at the first meeting of the Students' Medico-Chirurgical Society, on Friday, December the 12th, 1851.

TREATMENT OF ARTHRITIC HEADACHE.

By William Harvey, Esq.,
Surgeon to the Royal Dispensary for Diseases of the Ear.

In my last paper I endeavoured to point out the distinction between rheumatic and arthritic headache, showing that in the former the headache succeeded an attack of rheumatic inflammation of the structures of the ear, whereas in the latter the head becomes affected primarily, and the ear subsequently. Having also described other diagnostic symptoms peculiar to each, I now proceed to speak more fully of the treatment of arthritic headache. I have already alluded to the value of colchicum, in small and repeated doses, in those forms of the disease which are marked by tinnitus aurium and intermittent otalgia, as the result of gout in the cerebral mass. This medicine requires, however, judicious regulation; and not less important is the rigid attention to the hygienic rules advanced by recent authors on that subject, more particularly attention to the skin during its administration, combining with the colchicum antimonials and occasional vapour baths, the latter, I think, the more preferable. Dr. Todd's views on this point are so practical and important, and so accordant, for the most part, with my own experience, that I may be excused introducing them to the reader.

Colchicum should not be given in the asthenic form of gout.

Colchicum should never be given at the onset of a paroxysm, nor until the bowels have been duly acted upon by mild purgatives.

The first doses of the medicine should be very small; they may be gradually increased.

Colchicum should be always administered at first, uncombined with any other medicine, until the practitioner has satisfied himself that it is not likely to disagree with his patient; and indeed there is always a disadvantage in administering this medicine in combination with others, since it may become difficult, if not impossible, at times, to determine what effects should be ascribed to the colchicum, and what to the other ingredients.

It should not be administered so as to excite nausea, vomiting, or purging. These effects should be regarded as indicative of the unfavourable operation of the medicine.

Colchicum may be regarded as acting favourably when, under its use, the urine is increased in quantity, a more abundant bile is discharged, when the fæces, though solid, are surrounded by mucus, and the skin secretes freely.

The effects of colchicum should be carefully watched, as, like digitalis and other medicines, it is apt to accumulate in the system.

The use of this medicine seems chiefly applicable to the sthenic form of gout, which occurs in robust constitutions, and in the prime of life, but it is almost inadmissible in persons advanced in years, who have had several attacks, and in whom the malady would seem too deeply rooted to be influenced by the temporary administration of this remedy.

These aphorisms may not only be taken to be true in the limited extent to which Dr. Todd has applied them, but even in old age, with judicious management, I have found the medicine equally useful and necessary, with this reservation, that the doses should be so regulated as not to depress the system in any sensible degree.

The presence of this acid, or of its base—urea, in the blood of gouty people, may be said to be principally characteristic of this specific form of headache, if I may use the term; and if the uric element be not removed by appropriate treatment, the disease will most probably terminate in serious disordered action, either in the brain itself, causing the arthritic apoplexy, or else by a kind of repercussive metastasis, in the joints or organs usually affected by gout. The value of this medicine appears, indeed, to be better appreciated in proportion as its eliminative action on the kidneys is prominently kept in sight. In the November number of this journal Dr. Hughes Bennett has written some interesting observations on its

influence in connexion with other diuretics, in that species of coma which occurs as a sequela of scarlet fever. This appears, indeed, to be more readily explicable of the sedative influence of this extraordinary medicine than the attributing to it a primary action on the nervous system. It likewise assists in explaining its happy influence as an anodyne, which is often observable *after* its diuretic action has commenced, and not before. The oppression of the brain, which produced restlessness, and a sense of weariness, is relieved by the separation of the urea from the blood, which had previously acted as a poison to the brain.

In the earlier part of my remarks on this disease I have alluded to the risk attending the use of depletory measures in the treatment of this variety of headache, the injurious results which follow from the practice may be taken as one indication of the true nature of the disease under which the patient is labouring, when, as sometimes happens, an error in diagnosis, and consequently in the treatment, has been inadvertently made. The following case is a type of the primary seizure, and the result which follows:—

Case—J. B——, aged 43, a butler in a nobleman's family, was admitted a patient at the dispensary last spring. He stated that he had been suffering from severe headache, more particularly at the upper and back part, and a fulness in his ears, causing at times an imperfect hearing, and vertigo. His medical attendant, thinking it to be a threatening of apoplexy, advised bleeding and other evacuants; he was accordingly bled ad deliquium, but relief being only temporary, and the symptoms afterwards becoming more severe, the operation was repeated, with the effect of relieving him for one or two days only, other constitutional symptoms setting in obliged him to keep his bed. After some days he had a severe pain in his foot, his headache and giddiness being considerably relieved. He was shortly afterwards seized with an intense pain in the lobe of his ear, accompanied with swelling and redness; this continued to enlarge, and remained swollen for upwards of a month, and suddenly subsided; his head, in the meantime, was relieved, and he returned to his duties. Two months after another attack, resembling the first, caused him to repeat the treatment, with the like unsatisfactory result.

I saw this man shortly after, complaining of a heaviness in the side of the head on which the ear was affected, a continuous and distressing noise, aggravated towards evening, and an occasional pain, resembling a tic, on the side of the face and behind the ear. On inspection the structures presented nothing very remarkable beyond a dryness of the meatus, and a slight duskiness of the membrane of the tympanum; the hearing distance only two inches on the diseased side.

The treatment pursued was the administration of half a grain of the extract of colchicum, twice a day, a vapour bath three times a week, his diet regulated accordingly, no stimulants, and less animal food than he had been accustomed to. The case progressed with but little relief for ten days, excepting only that he became more tranquillized as to his feelings of nervousness, and a copious perspiration over the skin. He continued the colchicum for six weeks, with the gradual diminution of the tinnitus, and a considerable increase of the hearing distance.

It would be useless to continue the narration of this case further, the patient perfectly recovered after a period of six months, not only of the hardness of hearing, but of a troublesome scaly eruption with which he had been tormented for some years. The aggravation of symptoms after the bloodletting is too demonstrative of the injurious effects of depletion, and evidently and forcibly points to the caution necessary in all such cases when any large quantity of blood is drawn from the system.

Case.—Colonel C——, a corpulent and elderly gentleman, consulted me for a troublesome and heavy beating in his head and ears, always aggravated after meals, suffers from pains in the knees and ankles, and from some difficulty in swallowing, arising from a thickening of the mucous membrane of the pharynx, and some enlargement of the tonsils. When any freedom is permitted as to his appetite, the throat appears stuffed with a thickened mucus, and generally imperfect hearing, the meati on both sides were choked up with a deposit resembling gypsum, and although cleansed, repeatedly re-formed, accompanied with a discharge, leaving the meatus reddened and the membrane of the tympanum slightly opaque. These appearances I have so fully explained in a former paper On Arthritic Inflammation of the Ear, both in the acute and chronic conditions, that it will be needless again to recur to them.

This gentleman was advised to pursue a course of treatment resembling the former case, with the exception that he commenced by active cathartics for ten days. The course of treatment was continued for a period of nine months, with marked relief both to the chalky formation in his ears, and the threatened suffocation which he has been for years suffering from. These cases are not unfrequently presented with the thickened mucous membrane of the throat, causing a temporary obstruction to the Eustachian passage. Although freely relieved by catheterism, this tube does not remain long patent, and the case seldom does well without the adoption of the constitutional treatment before alluded to in these cases. Nevertheless, when the patient's sufferings are very great, and urgently demanding relief, I have found the internal exhibition of colchicum to be the most efficacious palliative; care should be taken, however, to direct its operation on the bowels early, either by small and repeated doses of sulphate of magnesia or the acetic extract of colchicum, which I prefer, in combination with colocynth, the circulation at the same time being attracted to the feet by mustard pediluvia. I have stated that it is not uncommon to find as a result, in many cases of arthritic headache, that the patients are seized with an obstinate discharge from the ear of one or both sides, more frequently of one, this discharge I have examined from time to time, and if allowed to dry on paper presents some of the earthy concretions; it is in these cases that colchicum will be found extremely beneficial. As a rule, these discharges should be encouraged, and if any application is used locally, none answers better or gives to the patient a greater amount of relief than cleaning the meatus occasionally with warm water. "I know (observes Otto in his Pathological Essay) a person in whom, during an atonic attack of gout, the whole mouth, throat, and gullet, are largly covered with a whitish mucus, which, when dried on blotting paper, left behind a large quantity of phosphate of lime. These tophi, as they are more commonly called, do not consist, as was formerly supposed, of the phosphate, but of the urate of lime, that is of uric acid, which we have spoken of as the probable proximate cause of gout, when it exists in the blood, and of lime in combination. This has been ascertained by chemical analysis, and taken with the preceding facts, may aid in explaining the causes and nature of gout in all its varieties. Further evidence in favour of this view is afforded by the fact, that during the decline of every fit of gout, uric acid or a salt consisting of that acid, with a base, generally ammonia, is largely deposited from the urine, and we also find that the use of alkalies and other antacids, which have an indefinite influence in diminishing the formation of urea, and in causing its elimination are at the same time among the best preventives of an attack of gout. All other facts tend greatly to show that the theory that gout is dependent on the presence of uric acid in the blood for its proximate cause, or at least that it is in some way connected therewith, if not absolutely demonstrated, is at all events far advanced on the road to direct proof.

This theory, however, is not altogether novel. The ancients had a glimpse of the truth, but only a glimpse. Their views were necessarily very crude and unsatisfactory, for want of the knowledge with which the vast and extraordinary progress made in animal chemistry of late years has so amply furnished us. They believed in the existence of a morbid fluid in the system, as causative of gout, but were utterly ignorant of its nature and character. This doctrine prevailed in a somewhat modified form, during the existence of the humoral pathology; but when

that failed these different views respecting the causes of gout were put forth. Of late years, again, the dogma teaching that the fluids in the system may be partakers in disease, as well as the solids, and may even be connected with the causes of constitutional and hereditary maladies, revived; and with it was revived the theory that referred gout to a morbid condition of the blood, or, in other words, that placed gout in the category of the blood diseases.

M. Bayle some years ago, published an essay on gout in the *Revue Médicale*, in which, when treating on the causes of the disease, he says they are unknown; but after carefully examining the pathognomonic symptoms, he is inclined to refer them to an alteration of some one of the humours, or as the result of a particular morbid fluid, produced under the influence of certain causes, and circulating with the other fluids in the economy. He especially mentions the occurrence of chalk stones as leading him to form this opinion; but probably he was not aware of their chemical composition, and therefore did not advance further than the threshold of discovery. Nevertheless, he believed that the morbid fluid, whatever it was, circulated in the blood; and, in confirmation of that view, cites the somewhat apocryphal case recorded in the Nuremburg Commentaries, where it is gravely stated that blood drawn from the arm contained small gravel! Later investigators have referred the proximate causes of gout to the presence of a morbid element in the blood; but it was reserved for Garrod to discover what that morbid element was. He distinctly ascertained that during an attack of gout the blood always contains uric acid, and that that body can be crystallized from it in the shape of urate of soda, the acid being either much less in quantity or altogether absent from the urate. Dr. Bence Jones has since confirmed Dr. Garrod's statement, the results of his own experiments having satisfied him as to their correctness. Mr. Forbes had, however, so far anticipated him as to have promulgated the opinion that the morbid material poisoning the blood was lithic acid; but he did not support his views by direct experiment, and, consequently, it is to Dr. Garrod that the profession is indebted for the elucidation of this important and interesting subject.*—*Prov. Jour.*

THE SO-CALLED MAGNETIC INDICATOR.

Of Mr. Rutter's honesty, I am perfectly satisfied, and for his courtesy I feel obliged; but when witnessing his experiments, and listening to his philosophy, I was inwardly convinced of the fallacy of the one, and the unsoundness of the other. On returning home, I repeated the processes he employed, and several others which have been described by that ingenious, but erratic and self-deceived observer, Mr. Mayo, in his recent volume on popular superstitions. The result has been completely confirmatory of my *a priori* impressions, and I believe the whole series of facts to be nothing more than the combined effects of muscular unsteadiness, and a non-suspected volition. I could detect no trace of magnetic, electric, or any other more recondite influences, but was able distinctly to assign the phenomena to the causes abovementioned. I wrote to this effect to Mr. Rutter, suggesting the performance of his experiments with *the eyes bandaged.* In reply, he stated *that he was aware that under such circumstances they would fail;* and I promised to withhold all further criticism, if, in his threatened book, he would preface every chapter by this admission. Really, Mr. Editor, philosophers are rapidly passing into their dotage, and it is high time for those who still retain a *mens sana in corpore sano*, to combine in the defence of the citadel of truth against their insane and desperate assaults.—*Dr. C. Cowan of Reading in Lancet.*

* "I have stated," says Dr. Graves, in his Clinical Medicine, "that gouty affections of the brain have long been known; and I am not sure that some of the older authors may not have alluded to gouty affections of the spinal marrow; but as our knowledge of the peculiar state of the brain and spinal cord termed ramollissement is comparatively recent, and not dating with any degree of accuracy earlier than the works of Abercrombie, Roston, and other modern authors, it is obvious that any observations made by the older writers concerning gouty affections of the nervous centres can have no distinct reference to this lesion."

POPLITEAL ANEURISM.

By J. Hilton, Esq., F.R.S., Surgeon to Guy's Hospital.

Hugh Moro, aged 43, admitted into Guy's Hospital, December 21, 1850. It appears from his history that he is a married man, and has followed the occupation of porter or labourer at one of the river side wharfs, where he was occasionally subject to exceedingly laborious work in lifting and carrying heavy goods. According to his own statement, he had enjoyed pretty strong and robust health, and had never been subject to gout or any other illness worthy of consideration, although in former life he was of debauched and intemperate habits—a fact which his aspect, his red blotchy face and tuberculated nose, at once suggested. No history of any family tendency to aneurism, but his mother, he said, died suddenly at an advanced age, of heart disease. The first indication he received of the disease which has led to his present condition, was almost a year ago, when he noticed his left foot and ankle swell and become painful at night, especially after a heavy day's work. Three months after this he discovered, quite accidentally, whilst one night rubbing his leg, a small lump about the size of a walnut, deeply situated in the left ham. Said that he did not observe any pulsation in it at first; but, on the other hand, he did not think anything seriously of it, and therefore did not pay much attention to it, as it occasioned him no pain or inconvenience. This tumour, then, which he had noticed nine months ago, remained persistent, and gradually but slowly increased in size. He did not, it appears, attach any importance to it until a fortnight before I admitted him into the hospital, when it became so painful and throbbed so violently, that he could not straighten his leg, or walk without much difficulty. From that time he got rapidly worse, and on his admission presented all the ordinary signs of popliteal aneurism. He had a large-sized, deep-seated, pulsating swelling in the popliteal region of the left leg, extending also to the calf, and rendering all the parts around tense and painful. This swelling increased in size by the application of pressure below it; but pressure on the artery above, at the pubes, both arrested its pulsations and much diminished its extent: in other words, the aneurismal sac could be almost emptied of its contents when pressure was made above; but on the removal of this pressure it immediately refilled, occasioning him at the same time a violent painful throbbing sensation. The usual aneurismal bruit was distinctly audible through the stethoscope placed over the tumour. I had him examined by the physicians, but the sounds of his heart were normal, and there was no evidence of the existence of any other aneurism. He was, as I have said, a man who had formerly drank largely and lived irregularly; he was a man whose looks betrayed a debilitated and broken-down constitution, and therefore one in whom the operation of tying the femoral artery would be exceedingly likely to lead to a serious if not fatal result. It was under this consideration that I determined to try pressure: a plan of treatment which appears to have proved very successful in the hands of some, but which, although often tried, has never yet succeeded in this hospital.

On the 22nd, that is, the day after his admission, I directed that his leg should be placed in a flannel bandage and supported on pillows in an elevated position, so as to diminish the supply of blood to the limb; and, at the same time, as he was suffering greatly from pain, ordered him morphiæ hydrochloratis, gr. j., omni nocte hora somni.

For a fortnight after his admission, during which time an apparatus was being made for the application of pressure, his symptoms presented little change, and I made no alteration in his treatment, with the exception of giving him occasionally an aperient to keep his bowels open. In a short time, however (January 7), he became the subject

of such intense pain all over the affected leg, that I was obliged, after giving him large doses of opium, which had but a transitory effect in alleviating his suffering, to delay no time in resorting to the method of treatment I had intended to pursue. Accordingly, about four p.m. of the same day, the instruments being completed, I adapted pressure on the femoral artery in its course over the head of the femur, by means of an apparatus which was fixed to the pelvis and supplied with an arm, to which the screw for compressing the vessel was connected. The other instrument I placed on the thigh about half way down, so as to maintain constant but alternate pressure by means of the two instruments. When he got tired of the one, to relieve him with the application of the other. A continued attendance was procured from amongst the pupils to change the pressure when required, and to ensure that it was constantly adapted so as to control, but not entirely arrest, the circulation of blood through the aneurismal sac.

According to the report, I see that the patient was much more easy and composed after the application of the pressure; and that although only at first able to bear it continuously for an hour in one place, yet in a short time he became habituated to it, and did not require its alteration oftener than every two or three hours.

On January 12th, as he complained of more pain in his leg, and there was more excitement about his arterial system, I ordered him tr. digitalis mxv., ex julepo ammon. acet., tertia quaque hora.

Notwithstanding this medicine, which much reduced his pulse in force and frequency, and the most careful and constant attention to the application of the pressure, his leg gradually became more painful, and his suffering so intense, that on the 15th all idea of his being able to continue the compression was abandoned, and the apparatus removed. I much regretted being obliged to discontinue the compression, for were I myself the subject of popliteal aneurism, I would rather submit to the application of pressure than the operation of tying, believing that it has proved in many cases a most safe and efficacious plan of treatment, and that many have been cured by it that would have probably sunk under the operation by ligature. In the case before us, from the severe pain the man endured, which was throughout a prominent symptom of his disease, the application of pressure could not be persisted in for more than eight days—a time not necessarily adequate to effect a cure of a popliteal aneurism. It would be unfair, therefore, to take this case as any criterion on the subject.

Two days after the apparatus for compression was removed, the patient was submitted to the operation of tying the femoral artery. There was no difficulty or impediment met with in the operation, which was in every way a plain and straightforward one. The patient immediately after the operation expressed himself as completely relieved of all distress, but in half an hour he was seized with such an intensely agonizing pain throughout the whole leg, but especially in the calf, that it was quite distressing to see him writhing from his sufferings. I ordered him large doses of opium, and by the advice of my talented colleague, Dr. Bird, the inhalation of the vapour of chloroform, but it was not till five or six hours afterwards that he obtained relief; and then he began to appear drowsy, and to doze at intervals. What the cause of this severe pain was, I am almost at a loss to explain. It could not have resulted from a nerve being included in the ligature, as I was careful to avoid such an occurrence, and he was quite free from pain during half an hour after the operation, a fact inconsistent with the possible inclusion of a nerve within the ligature. Again, the pain was distributed all over the leg, but especially severe in the calf, which receives its nervous supply from the great sciatic, a nerve far remote in position from the femoral artery. I think, therefore, there is most probability that it resulted from some cause or condition which existed previous to the operation.

On recovery from the paroxysm of pain which I have just noticed, his symptoms assumed a favourable aspect for the first few days succeeding the operation, and he has not since had a recurrence of his suffering. Other symptoms, however, have occurred which but too plainly predict the serious, nay, hopeless, nature of his case. His pulse from being quiet is now quicker and more feeble; his tongue, at first moist and clean or only slightly furred, is now brown and dry; his skin sweats profusely; his brain is no longer undisturbed, but affected with delirium; the wound is unhealthy in appearance, and for some days past has presented no sign of reparative action. The aneurismal sac, at first presenting a favourable appearance, grew harder and diminished in size, but afterwards got softer and contained a quantity of dark grumous offensive material, which I evacuated by means of a lancet. In addition now to all his other symptoms, his foot is blue and cold, and he has commencing gangrene of the leg, which, if he do not previously die of secondary hæmorrhage, will inevitably lead to his dissolution.

[The patient lived a few days longer, and then died. The gangrene spread from the foot and reached more than half way up the leg, and was accompanied with the formation of numerous vesicles containing an offensive bloody serum. Several of his joints became tender and painful; his pulse extremely quick, feeble, and irregular; his respiration encumbered with bronchial râles, and his expectoration tinged with blood. Frequent twitchings of the muscles of the head and upper extremities occurred; consciousness entirely left him, and in this state he died.

The autopsy disclosed purulent fluid in his left shoulder and knee-joints, accompanied with a general phlebitic state of the system. The ligature placed on the femoral artery at the operation still remained, not having separated during life. After death the limb was injected with coarse injection. The femoral artery was found pervious to within about an inch of the part to which the ligature was applied, but had become abruptly smaller at the point of separation of the profunda from the trunk. The profunda artery had acquired increased dimensions, and the same may be said of its terminal branches, especially those ramifying in the vastus externus and flexors of the knee-joint, where a complete anastomosis became established between the popliteal and femoral arteries, through the medium of branches derived from the former of the two. The femoral artery below the position of the ligature was occupied by injection acquired through the anastomosis already adverted to, so that the neighbourhood of the knee-joint was exceedingly well supplied with blood. Below the knee the limb was gangrenous, and the blood-vessels impervious. The branches of the gluteal and ischiatic arteries were somewhat enlarged. The aneurism was found connected with the popliteal artery, and situated behind the knee-joint in the popliteal space. The whole limb has been preserved, and a dried preparation made of it, which has been placed in the pathological museum of the hospital.]—*Med. Gaz.*

Transfusion of Blood; Successful Result.—M. Devay of the Hôtel Dieu of Lyons, has just performed the operation of transfusion upon a young woman reduced to mortal debility by hæmorrhage (the *Courrier de Lyon* does not mention the kind of hæmorrhage). The blood was kindly furnished by M. Lardet, the house-surgeon, and the patient revived by the introduction of the warm and healthy vital fluid. Three days after the operation the symptoms were very favourable, and we learn by further accounts that this effect has not been merely momentary, but has been followed by complete recovery, or rather a kind of resurrection, the patient being now fully convalescent. These results have been deemed so important by the Dean of the Faculty, Dr. Richard, that he mentioned them in his introductory discourse at the opening of the winter session, bestowing the due meed of praise both on the physician and the house-surgeon, M. Lardet, who so readily consented to part with a portion of his blood.—*Lancet.*

NEW COMPOUND OF VOLATILE OIL OF TURPENTINE.

By M. A. Sobrero.

Humid volatile oil of turpentine rapidly absorbs oxygen under the influence of light. A crystalline substance is formed, the composition of which we cannot express by means of any of the formulæ, at present known, of the different hydrates of essence of turpentine. In order to obtain this body, a flask, filled with water, is to be inverted in a water bath, and oxygen gas passed into it, to about four-fifths of its capacity, then volatile oil of turpentine is to be introduced in sufficient quantity to form a layer of about half a centimetre, in tkickness, in the flask. The apparatus thus arranged is to be exposed to the direct action of light, In a short time there forms, on the internal surface of the flask not touched by the water, a crystalline body, which takes the form of small prismatic needles, the size of which gradually increases, and after a few days, are sometimes a centimetre or more in length. At the same time the liquid rises in the flask, which would become filled, if care were not taken to arrange the apparatus in such a manner that the air may pass through while absorption is taking place. By arranging several flasks in the manner described, a considerable quantity of this crystalline body may be obtained. In order to separate and purify this body, the flasks are to be removed from the baths in which they were immersed, and, after having allowed the oil and water to run off, a small quantity of alcohol is to be poured in, which rapidly dissolves the crystals. The solutions added together yield, by evaporation, the crystalline body coloured with oil of turpentine. It is purified by means of repeated crystallizations in alcohol and in water. This body is inodorous ; it is soluble in alcohol, in ether, and in water. Its aqueous boiling solution yields it in long prisms, which assume a star-like arrangement. This body decomposes when boiled with water, slightly acidulated by sulphuric acid, and yields a volatile product, having a pungent odour resembling that of oil of turpentine or camphor. This latter character distinguishes it from the hydrate of turpentine of Wiggers, which, by the same reaction, gives an oily volatile body, with the odour of hyacinths.—*Repertoire de Pharmacie* and *Phar. Jour.*

CANCER OF THE JAW EXTIRPATED.

Notwithstanding it has been urged against the extirpation of cancerous parts that the disease is never cured by it, and that if in some favourable instances it effects a suspension of the march of the disease, it in the greater number really hastens the fatal termination, yet this verdict, though promulgated under high authority, would require to be received with some reservation.

What purpose would it answer to prove that in nine cases out of ten the disease does return and destroy the patient? Would not all the ten cases have certainly proved fatal if not operated upon? So important does this subject appear, that we trust our readers will excuse us if we go at some length into the reasons which seem to bear on interference with cancerous diseases.

1. Operating undoubtedly saves some patients, and in others is followed by no return of the disease for many years: thus assuring a long interval of ease and some prolongation of life.

2. When the disease does return it is not more fatal, for that is impossible, than at its first appearance ; and its being more rapidly fatal can scarcely be, in common humanity, considered as an objection, as then the struggle is shorter and sooner ended.

3. It is better to save even one patient out of twenty than to lose them all without a struggle ; for it may be assumed as nearly a general rule, that at the period when patients will allow the operation to be performed, the disease is always so far advanced that it would of itself destroy the patient.

4. Most of the operations for cancerous diseases are not of a nature to endanger life, and owing to the discovery of chloroform, not likely to be attended with severe suffering.

Finally, the exact proportion of cases in which cancer returns after removal by the knife, to those in which patients live the rest of their days free from its invasions, is not well known ; and till this is done no part of the question can be looked on as satisfactorily settled. Extended and complete series of hospital reports and clinical histories of individual cases will in time go far to yield materials for arriving at a definite solution of the difficulty.

But though a high authority (Dr. Walshe) has told us that, " undoubted cancerous tumours have, both before and after ulceration had set in, been cured or rendered perfectly innocuous by one or other of a variety of natural processes occurring spontaneously ;" that " an unbiassed survey of recorded experience does not warrant the notion of the invariable incurability of the disease by medicinal means at any stage of its progress ; and that testimony, which I am enabled to corroborate from my own observation, is not deficient to the fact that growths, cancerous in essence, may at an early stage be totally removed by a persevering use of certain external and internal remedies ;" yet scarcely a surgeon is to be found who places even the slightest reliance on any means either of cure or of arrest, except the knife, and we learn from the very writer who gives us such consolatory hopes that, " in a certain number of instances, all medicinal agents not only fail in influencing the disease favourably, but if persisted in, would infallibly exasperate it." Here unfortunately as in too many instances no guide exists to enable us to distinguish before hand, those cases which will, from those which will not bear treatment.

Mr. Simon's patient, a man aged 45, was recently admitted into St. Thomas's Hospital, with epithelial cancer on the right side of the lower jaw. The following history was transmitted by his medical attendant to Mr. Simon, and kindly communicated to us by Mr. C. T. Richardson. His occupation was that of watchman to the Rochester Oyster Fishery, and he had been in the habit of living in a fishing boat for six weeks at a time, his only relaxation being an occasional visit on shore, which lasted from the Friday to the Monday. During his residence in the boat, he procured himself provisions at Upchurch, a village situated at ten miles distant from the fishing station. In November of last year his mother died. He seems to have been attached to her ; and, though always unsteady, now began to drink as hard as his circumstances would allow, being drunk the whole time he was on shore, and probably procuring drink when he sent for his provisions. He has never been well since his mother's death, and has complained of rheumatism of the jaw, as he termed it, for the last twelve months. Some time between the 1st and the 14th of June, 1851, he pulled out a tooth in the situation of the tumour, which had not then appeared: this he did to relieve the pain in the jaw, in which, however, he was disappointed. From this date the tumour made its appearance, and it had progressed considerably by the 14th of August, the time he was first seen by his medical attendant.

" When I first saw him (this gentleman says in his communication), there was a hard swelling over the lower jaw on the right side, with a fungus springing from its buccal surface. Hæmorrhage first occurred about the 28th of August, when a pint or more of blood was said to have been lost. It recurred to a less extent several times before he was admitted into St. Thomas's Hospital." On examination, the tumour was found to be seated on the right and external surfaces of the lower jaw. It was of considerable size, and extended from the angle a good way towards the symphysis, bulging out the cheek, and so adherent to the mucous membrane and skin that Mr. Simon was compelled, when performing the operation, to remove a considerable portion of this at the same time. The tongue was thrust over towards the left side of the mouth. The tumour was of irregular form, and its lower margin barely permitted the inferior edge of the jaw to be felt below. As there was now daily hæmorrhage from the tumour, disturbed rest, and loss of appetite, Mr. Simon was induced

to operate at once, especially as epithelial cancer of this kind is less liable to return than any other variety of the disease. Instead, however, of detaching the jaw-bone by sawing it across anterior and posterior to the seat of the disease, the operator removed the whole half of the bone at its articulations, considering that each half is in pathology a separate bone, and that the only chance of safety lies in not leaving any disease behind. Only a very small portion could have been saved, which would have been of no use, and might have contained the germs of disease. During the first twenty-four hours after the operation, a great deal of the nourishment which was given him escaped, partly by the wound, and partly by the mouth. The man was too low to allow of anything like starvation; and therefore it was deemed advisable at once to resort to artificial support. A flexible catheter was used as a feeding tube, and introduced through the nostril, thus allowing a supply of food to be conducted to the stomach without any impediment. The case succeeded remarkably well; great part of the wound healing by the first intention; and, within a fortnight, the whole line had closed, except where the elliptical portion had been removed on account of adhesions. This left a fistulous opening, which Mr. Simon proposes, should it not close, to pare, and bring the ends together, anticipating then a complete union of the wound.—*Med. Gaz.*

ON CAMPHINE.

The following directions for preparing camphine for lamps are contained in the *Wochenschrift des Polytechn. Vereins in Würzburg I. Yahrg. No.* 5: take one pound (Bavarian avoirdupois weight) of purified oil of turpentine, free from resin, one ounce of pure sulphuric ether, and half an ounce of camphor. Dissolve the camphor in the ether, add the solution to the turpentine, and apply a gentle heat until the liquid becomes as clear as water. Oil of turpentine may be purified by impregnating the saw-dust of pine tree-wood with the oil of turpentine, introducing it into a still arranged for distillation by steam, and distilling the oil over in the usual way, by conducting steam into it. The oil is then heated, in order to deprive it entirely of the water which has passed over during the distillation, and is then to be decanted. The residue in the still, consisting of saw-dust and resin, mixed with coal-dust and clay, can be advantageously employed as fuel.

Dr. Buchner's opinion is, that the addition of camphor is quite superfluous, and also that the proposed method of purifying the oil is quite unnecessary. For if the oil is cautiously shaken with a proportionately small quantity of sulphuric acid and then left standing, a dark-brown charred resinous substance separates with the water, and the oil, when poured off, although of a yellowish colour and changed odour, appears perfectly adapted for the camphine lamp. Too much sulphuric acid, however, must not be added at once, because in this case a violent reaction takes place, accompanied with a strong development of heat, and a large portion of the oil of turpentine would then become volatilized. Dr. B. thinks it probable that in England rectified coal-tar oil is sold and consumed as camphine. The pound of camphine is sold in Bavaria for twenty-four to twenty-seven kreuzers, equal to ninepence.

In order to determine the respective values of camphine-light, oil-lamp-light, gas-light, and wax-candle-light, the society for promoting arts and trades in Hamburg has instituted a number of photometric experiments, made under the superintendence of Messrs. Bubendey, Plath, and Ruete, which have been published in the *Jour. f. Prakt. Chemie*, lii., 314. The oil-lamp employed in these experiments was the so-called Carcels-lamp, as described in Knapp's *Lehrbuch f. Chem. Technologie*, i., 124.

The lamps were arranged and lighted about two hours before the commencement of the photometric comparison. In order to determine the consumption, the lamps with their contents were weighed before lighting and at the close of the experiment. The photometer employed was one of Wright's, and the gas-lamp was provided with a so-called economical burner, and gave at a pressure of 0.6 inches before the burner, and a consumption of five cubic inches per hour, a light of 17½ wax-tapers, of thirteen inches length, six to the pound. In order to obtain more exact results, the experiments were reduced to the cost of light during twelve hours, which was for the gas-light 3 83, equal to 0.447*d.*; camphine lamp 1.35, equal to 0.858*d.*; Carcel-oil-lamp 10.42, equal to 1.2*d.*; wax-taper 82.80, equal to 9.7*d.* In a second experiment, in which the proportions of intensity and cost of light during twelve hours were not compared with a gas flame, but directly with a wax-taper of the length and weight stated above, the relative cost was, gas 3.83; camphine 6.25; oil 8.15; wax 82.80. The intensities of the different lights were, gas-flame, with a burner of twenty holes and 11.16 diameter, 17½; camphine lamp 11; oil-lamp 10½; wax-taper. The relative cost for an equal intensity of light by these four materials during an equal space of time would be, gas 16; camphine 29; oil 39; wax 346.—*Buchner's Repert.* and *Phar. Jour.*

THE OFFSPRING OF DEAF AND DUMB PARENTS.

Of about 200 deaf mutes who attended a festival at the asylum in Hertford, last September, 103 had been or are now married. Both parties were deaf and dumb in forty of these marriages; in twenty-three one could hear and speak. From the thirty-fifth annual report we learn, "that thirty-one of these couples had not become parents, but the remaining seventy-two were the parents of 102 children, of whom ninety-eight could hear and speak, and *four* only were deaf and dumb. One of the four was the only child of his parents, both of whom were congenitally deaf. Besides the parents, the paternal grandfather, a sister of the father, and two sons of this sister, were deaf and dumb; and on the mother's side, an aunt of the child was deaf and dumb. In the other family, that of the three children, the father lost his hearing by disease at two years of age, and had no known relative deaf and dumb. The mother was born deaf, and had a deaf and dumb brother. These were the only cases of the kind present at the festival. The question, whether the children of a deaf mute parent are more likely than others to be deaf and dumb, has not been solved in any other country so satisfactorily as in our own. In Europe comparatively few of the deaf and dumb have married, and those we believe have generally selected hearing partners. Here, however, in the large majority of cases, both husband and wife are mutes. The percentage of deaf children, the offspring of such marriages, is undoubtedly somewhat greater than among an equal number of the children of other parents, taken like the deaf and dumb from the various conditions of life. But if the facts above stated afford a fair criterion for judging on this question, we are safe in the belief that this result might be obviated in a great degree, if *intermarriage* could be prevented between those deaf mutes whose parents or other near relatives seem to have been constitutionally prone to the infirmity of deafness. This could only be done by moral suasion; but if influential people, and especially the parents of deaf mutes, were deeply impressed with the idea that marriage should not take place between two persons, each belonging to a family in which the great evil of deafness was constitutional, lest the offspring of that union should be deaf and dumb, much might be done towards preventing the extension of the evil. But there are other facts on the subject which would seem, at first view at least, to confound the speculations we have based on the cases above mentioned. For instance, a husband and wife, once pupils here, were both congenitally deaf; but neither, as we believe, has had any deaf and dumb relative, except their three children, and these were all deaf from birth. The circumstances of another of our former pupils and his family connexions are as follows:—His brothers and sisters hear, and they married hearing persons. One of the brothers has two deaf and dumb children, one sister has one, and another

two deaf and dumb children, and one of the latter has a deaf and dumb child. There is, besides, one other deaf mute in the circle of relatives—possibly more than one, though no one of the ancestors is known to have been a deaf person. The man first referred to married a deaf and dumb woman, *and their five children all hear and speak.—Boston Medical Journal.*

ADULTERATION OF SCAMMONY.

By M. Thorel.

In expressing the opinion, some time ago, that the resin of scammony was the part of the drug that ought to be administered as a therapeutic agent, I conceived that this resin ought always to be prepared by the pharmaceutist himself. Whenever the pharmaceutist, from any cause, is prevented from preparing it, and is obliged to purchase that which is met with in commerce, it is necessary that care should be taken to ascertain that it is pure. Any adulteration would soon be discovered, unless the substance added was in small quantity or its action similar to that of the resin itself. Resin of jalap being of the latter class, and being at the same time cheaper than resin of scammony, has been used for adulterating it. The fraud is a very unjustifiable one, notwithstanding the fact that the substance used is somewhat similar in action, for no substitution of one agent for another should be tolerated in medicines. I propose, for the detection of this fraud, a method which is founded on the perfect insolubility of resin of jalap in rectified ether, and the solubility in all proportions of the resin of scammony in this menstruum. There are other substances, besides resin of jalap, which are used for adulterating resin of scammony, such as resin of guaiacum and colophony, and these are still more objectionable, as they are inert. Resin of guaiacum may be easily detected by means of nitrous acid gas, or bichloride of mercury. There are several reagents which may be used for detecting the presence of colophony in resin of scammony. Among them is oil of turpentine, which dissolves colophony at common temperatures, and leaves resin of scammony almost wholly unacted upon. But the best reagent for this purpose is sulphuric acid, which possesses the property of dissolving many resins, and of modifying more or less, their composition. If a little of this acid be poured over colophony, it immediately, and by simple contact, developes an intense red colour. The same acid, when poured over pure resin of scammony, produces, on the contrary, no immediate change; it is only, after the lapse of some minutes, and with contact of the air, that it becomes coloured, and then but slightly, the colour being that of wine dregs. By this means, the presence of one-twentieth part of colophony may be detected in resin of scammony. For this purpose, it is only necessary to put 25 or 30 centigrammes of the resin into a glass or porcelain mortar, to add four or five grammes of the oil of vitriol of commerce, and to rub it with the pestle. If the resin of scammony should contain colophony, the mixture will at once become red, but if on the contrary it is pure, it will only become coloured after some time.—*Repertoire de Pharmacie* and *Phar. Jour.*

Oil of Pitch in Eczema.—The French medical periodicals have of late spoken very highly of the efficacy of the oil of pitch (huile de Cade) in the treatment of eczema. Indeed, M. Devergie, physician to the Hôpital St. Louis, where diseases of the skin are especially treated, advocated the oil several years ago, and has lately taken an opportunity of stating that this "huile de Cade" should be preferred to the empyreumatic oil obtained in the production of coal gas, which has been highly eulogized by M. Lafond Gouzi. Dr. Neligan, in his work on Materia Medica, states that the "huile de Cade" has been used on the continent in obstinate cases of herpes, lichen, and eczema, but observes that the term "huile de Cade" (oleum cadinum) has been restricted by some French pharmacologists to a tarry oil obtained by the dry distillation of the wood of the Juniperus oxycedrus.—*Lancet.*

EFFECTS OF VIRULENT MATTERS TAKEN INTO THE STOMACH.

M. Regnault, director of the Veterinary School at Alfort, gives the following summary of his researches:—

1. The dog and pig may eat all the products of secretion, whatever they may be, without prejudice to their health; all the cadaveric debris proceeding from animals suffering under glanders, furuncular disease, rabies, the contagious typhus and pneumonia of oxen, and the contagious epizootics of fowls.

2. It is not the same with fowls, unless perhaps with the exception of their own diseases, in order to determine which it would be necessary to make the experiment out of the epizootic atmosphere, which M. Regnault has not been able to effect.

3. The virulent matters of rabies and acute glanders, which lose their contagious properties by transit through the alimentary canal of the dog or pig, retain them in passing through that of the horse.

4. The matter of the furuncular disease which is taken with impunity by the dog and pig, gives rise to disease when swallowed by the herbivora, the sheep, goat, and horse.

5. Carnivora and omnivora eat the matters with impunity, because their organization is adapted for the conversion and digestion of animal matters, while that of the herbivora is suited only to the digestion of vegetable substances.

6. The flesh of the pig that has eaten these virulent matters is perfectly safe for human food.

7. Culinary operations so change the poisonous nature of the matters proceeding from animals with either of these contagious maladies, that they have been swallowed with impunity by herbivora.

From these conclusions the author draws the inferences, that there is no reason, in a sanitary point of view, for preventing pigs, fowls, &c., being fed on such matters; and, that however repulsive it may seem to the human being, meat, milk, &c., of animals suffering under contagious maladies may be eaten with impunity, if previously cooked or boiled.—*Med. Gaz.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 24, 1851.

PROCEEDINGS OF GUARDIANS UNDER THE DISPENSARY ACT.

We are obliged in this day's publication to occupy the space usually devoted to general observations on passing events with replies to the numerous queries submitted to us respecting the operation of the new law, and such information respecting the divisions of unions and settlement of salaries as have come to hand. The Kenmare Union has been divided into four districts, with salaries of £100, £80, and £60. Mr. Townsend observing, that the taxation should not exceed 6*d.* in the pound; but if salaries were so given it would come to 8*d.*; the local paper (the *Tralee Chronicle*) giving utterance to the chagrin of the ratepayers, by stating that "the doctors were pensioned off" at these sums. The Cahirciveen Union has been divided into four districts, with salaries of £85, £80, and £60. Granard Union into five, with salaries of £60; the gentlemen of the Board being for higher salaries, but outvoted by the *profanum vulgus*. At Robertstown, in the county Kildare, we hear of subterraneous movements of suspicious appearance to promote the appointment of an influential's man. The Committee of the Robertstown Dispensary have petitioned the Commissioners against the division made by the Naas Guardians, as well as against the amount of salaries. In Carlow Union we find a curious reason assigned for giving the Surgeon of the Tullow District the inadequate salary of £64. It is considered a suitable remuneration,

because, indeed, he is paid £56 a year for attendance on the Fever Hospital—an institution of a totally different description. We shall presently have low salaries assigned to men because they are in good practice. In the neighbouring Union of Athy, a different feeling prevails, the salaries being £90, £100, and £120. In the Mountmelick Union, Queen's County, the salaries are shabby for such an union: £60 to £70.

PROCEEDINGS OF UNIONS—FERMOY UNION.

The Board of Guardians of the Fermoy Union have recommended that it be divided into five districts, with two dispensaries or offices in each; that only five medical officers be appointed; that they be required to attend on alternate days at each office; and that their salaries be £75 per annum. The four rural districts vary in length from ten to fourteen miles, with areas of about 32,000 acres each; that connected with the town of Fermoy is eight miles and a half by six and a half, with an area of 19,000 acres.

Heretofore there have been nine dispensaries in the union, each with its own medical officer, and that of Fermoy employing and paying an apothecary as well as a physician.

Two large and remote electoral divisions have been annexed to the town, never before having had connexion with it; and another electoral division, which lies contiguous and always made part of the old dispensary district, has now been separated from it. No weight seems to have been attached to the facts that the population of the town amounts now to over 7000, and in consequence of the presence of a large garrison is of more debauched habits, and more diseased than usual in places of similar size; that there is a large bridewell to be attended, and that the dispensary has always been open daily.

The dispensary surgeons naturally feel the greatest dissatisfaction; they say truly that it is monstrous on the part of the board to attempt to force them to undertake double work and at the same time reduce their salaries.

KILLARNEY UNION.

The Chairman said that they were now called on to take into consideration the Medical Charities' Act. A great deal of misapprehension was abroad in regard to the powers of boards of guardians, whose duties in relation to this act were confined to two points—namely, to define the boundaries of districts, and to recommend what may be considered a fair remuneration for the medical officers. It placed no patronage in their the (guardians) hands, and he was glad of it. It was mandatory on them to ascertain the amount of duties which were to be performed by the physicians. Relief under the act, as was supposed outside, was not indiscriminately to be given; it was only to those whom the committee of management might consider unable to provide medical assistance, and such relief should be administered only under an order from such committee. The relief may be two-fold. If not urgent, it would be dispensed at the dispensary establishments; but if urgent, the medical officer should, no matter what the inconvenience might be to him, and however great the distance, attend. The Chairman having, at some length, contrasted the expenses of dispensaries under the old and new system, proceeded to say that taxation had reached a fearful point in this country, and that as this act would inflict an additional burden on the ratepayers, the board should cut out as large an area for a district as would be found consistent with the efficient discharge of the duties to be performed. These duties might at first sight be looked on as very laborious, but when it was considered that the great bulk of those to whom the act applies will be concentrated in the workhouse, it will not appear so. The valuation of the union being now £62,000, two pence poundage would give £515, which he considered would be fully sufficient, under proper local management, for all objects—for the payment of the medical officers, the supply of medicine, and the rent of houses. Under the old system the cost was greater, and future prospects gave hopes that it would be less. He had given a great deal of consideration to this question, with the view of placing before the board of guardians a judicious arrangement of localities, based on valuation and population. It would be for the board to satisfy themselves; and as he apportioned the union by this arrangement into four districts, necessarily for four doctors, it would remain for some guardian, in reference to salaries, to say what these should be—whether £80 or so.

Mr. M. D. Brennan—The most active man in the country could not journey in one day over any of these districts attending patients.

Mr. McKenna would be prepared to propose five instead of four districts.

Mr. O'Connell had great pleasure in proposing the adoption of the correct and satisfactory arrangements of districts suggested by the chairman, than whom no one was more competent for such a task. He (Mr. O'Connell) considered this law as one of the greatest humbugs: he would accept, under the chairman's regulations, the best use that could be made of it. Mr. McKenna would have more dispensary districts. Did he know that the Tralee union was larger, and there they had only four medical men? It was in vain to shut their eyes against the state of the country, or against the pressure on men depending for support on land. Such distress existed, and such was the system of taxation, that the moment the opportunity offered the cry was tax the land. The moment an opportunity like the present occurred, men in every quarter were busy for the interests of their friends, no matter where the funds were to be found—no matter how stood the burden of taxation. But two pence in the pound was trifling! So were the items which made the aggregate of the national debt. He would not complain of taxation for what would really benefit the public, and he could not conceive that the tomfoolery of the act would do that. It was only the very poor and stricken-down who could be relieved by it, and were not seven-eighths of that class in the workhouse? But as it was law, and should be obeyed, he would therefore propose the division into four districts.

Mr. McKenna—I defy any medical man to discharge the duties through a tract of country sixteen miles by twelve; and looking on the act as a boon to this country, and superseding the folly of the old expensive system, I will call on the guardians to extend liberally its benefits to the poor. For myself, I have no friend to support, nor a job to carry. I move that five districts are the least possible which the union ought to be divided into.

The Chairman would now put the question to a vote. The division was 20 for the original motion, and 12 for Mr. McKenna's amendment.

A lengthened conversation then ensued as to whether the salaries should be equalised or proportioned in the ratio of valuation and population.

Mr. Herbert, M.P., considered that the area was an important point for consideration, for though the Killarney district presented a population far greater than any of the others, yet they were more concentrated there, and more scattered over others.

The equalisation of salaries being settled,

Mr. O'Connell would say that jobbing was the curse of Ireland. Men, now-a-days, looking for public situations, should be content with salaries smaller than in former times. Her Majesty's ministers set an example, and it ought to be practised in every public department. He had two medical friends whom he would like to see independent and happy, Dr. W. Murphy and Dr. T. D. Maybury, yet, in their public capacity, he thought they should be content with moderate salaries, and thinking so, he (Mr. O'Connell) would propose £60 a year.

Mr. M. D. Brennan—Oh! only 3*s*. 4*d*. a day, a butler's wages.

Mr. O'Connell—Very good in these bad times.

Mr. Bland proposed as an amendment £50 a year.

Mr. Richard Maybury begged the board to consider that they were dealing with educated professional men, who had lost much to a profession which ranked the first in all nations. He trusted that the board would not, so far as salary was concerned, place them on the same level as the relieving officers, who, however respectable and intelligent, were not obliged by social position to keep up the appearance of gentlemen. He (Mr. M.) would say £80 a year.

Mr. McKenna inquired if it were right for him to move a second amendment?

The Chairman said it was.

Mr. Bland's amendment was then negatived by a majority of 31.

Mr. Herbert—Mr. Maybury says £80 and Mr. O'Connell £60, and as Mr. McKenna is about to propose £70, I would recommend it as a compromise. The more unanimity that prevails at this board on this question, the more effect it will have on the Commissioners.

Mr. O'Connell and Mr. Maybury having acceded to the suggestion,

Mr. Bland made some observations conveying his dissent.

Dr. T. D. Maybury, who attended as local secretary of the County Medical Club, said that he would then advise the rural guardians to support the higher salary.

Mr. Bland thought that Dr. Maybury was only present by courtesy, and ought not interfere with the guardians.

Mr. Richard Maybury assented with the view of unanimously carrying out Mr. Herbert's suggestion. He (Mr. M.) thought that £80 was even too small, but the respected chairman in his introductory observations having suggested it, he (Mr. M.) adopted it, and he now considered it unfair of Mr. Bland to come forward again after the decisive opinion of the board.

Mr. Bland would keep his temper, but he would say that no guardian should tell another that he acted unfairly.

Mr. M. D. Brennan moved £90; but the proposition not having been seconded, fell to the ground.

WHETHER ONE SURGEON CAN HOLD TWO DISPENSARIES.

We have had several inquiries on this subject, notwithstanding our reply some time ago. The act neither forbids nor suggests such appointments, and it must therefore be decided by the Commissioners in the code of regulations they are required to enact. If one man be considered equal to the duty of two districts, they will naturally ask why the two districts have not been comprised in one. As we have already said, the danger is lest such an arrangement should lead to the payment of one salary for double duty, or to the enlargement of districts, on the plea that in certain cases one man has been found willing to take charge of two ordinary ones.

ELECTIONS TO DISPENSARIES.

In reply to a Correspondent: if the Commissioners do not name the present Surgeons in the new Districts to the new Dispensaries there established, which they are authorized by the act to do, the new Dispensary Committee must make the appointment; such Committee being the Guardians elected and *ex-officio*, and the ratepayers placed on the Committee by the Guardians. As to the appointment of an unqualified man, the act permits such to be continued, if "in possession" of a dispensary retained for the service of the union. All regularly-educated Surgeons are eligible, as they were before the passing of the act, and no holder of an apothecary's licence, or any sham certificate, whether called diploma or not, can be legally appointed. On this point all must be firm, for if ever the line of demarcation be broken which separates the regularly-qualified man from the pretender, utter ruin to our profession must be the consequence.

APPOINTMENT OF PHYSICIANS AND SURGEONS TO THE COMMISSION OF THE PEACE.

A Correspondent requiring information on this subject will find it in some of our numbers of early date. An attempt was then made to disqualify the members of our profession from holding such an office, but it was abandoned: whether any edict of the kind has been issued, we cannot tell, but inquiry shall be made. We must not submit to any arbitrary decree affecting the character of our profession, or expressing in any way a determination to deal with it otherwise than as a section of the community fully entitled to a consideration equal to that given to any other. We have not forgotten the attempt made by one high in authority some years ago to prevent Physicians and Surgeons from acting as Poor-law Guardians. Had it succeeded, we should not now have the valuable aid found in many unions.

TO CORRESPONDENTS.

We have endeavoured to reply to the numerous questions submitted to us this week, and have experienced considerable difficulty in doing so in consequence of the arrival of letters while preparing to go to press. The question as to the class of patients entitled to relief under the new law cannot be answered until its practical application comes to be tested. The act says that relief is to be given to "poor persons," not using the word pauper, and is therefore probably to be interpreted as making provision for the medical relief of persons unable to obtain such aid; but to check the prevalent abuse of administering it to those able to pay, the Dispensary Committees are armed with a power to erase the names of such from the lists of patients. We have not time to notice the proceedings in the Millstreet and Kanturk Union in the present number, but propose to do so in our next, as they suggest some inquiries respecting the general operation of the act.

MATHEWS *v.* HARTY AND STOKES.

We refrain from comment on this extraordinary trial until the present state of excitement, public, legal, and medical, cools a little. Time must be allowed for the restoration of that equanimity and calm judgment which the question demands. We have not had leisure to study the case, but from a cursory view of it, we fear that we may find it difficult to adopt the popular view.

MINOR APPOINTMENTS UNDER DISPENSARY ACT.

In reply to a Correspondent, we hear nothing of new clerks or other officers, but such must be required for the increase of business. The Commissioners will of course be the parties to provide them, and they have probably been already hired.

CORRESPONDENCE.

THE NEW DISPENSARY ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

My dear Sir,—Being an old subscriber to the Medical Press, and feeling conscious that you have been an honest, honourable, and able supporter of the rights of medical men, I have taken the liberty of troubling you with a few queries about the working of the new medical act.

Can you inform me what will be the duties of a medical attendant of a dispensary in a rural district? Will he have to attend the *destitute poor only?* or will he have to attend all the servants of the gentry and farmers in his district, together with their poor tenants, or those the committee may consider poor?

It appears strange to me, that no person gave a reply to Mr. Senior at the Belfast board, when he stated "that £75 a year was high for a medical man, when compared with those paid in England, &c." If I am rightly informed, it is only the destitute poor who receive medical relief there, and medical men suit their fees to the circumstances of their patients, and by doing so, are enabled to make money and live respectably.

I need not inform you, that in Ireland heretofore, with a few, very few honourable exceptions, there is no device, scheme, or plan which could be devised or invented, but has been put into requisition to deprive medical men of the just reward of their labour and skill. I trust and hope, in future, the profession will be true to each other and their own interests; the more, when they know that it is one in a hundred reaches sixty years; and that they are only a secondary consideration in the working of this new bill; in fact, looked upon as a necessary evil, to be worked until they can do no more, and then cast off.—I am, sir, your obedient servant,

An Old Subscriber.

REMUNERATION OF MEDICAL WITNESSES.

TO THE EDITOR OF THE MEDICAL PRESS.

Dear Sir,—Since everything which injuriously affects the interests of our profession legitimately concerns the watchful medical journalist, permit me to direct your attention to a grievance of no inconsiderable magnitude to which medical men of every rank have recently become exposed, and to which, from the general silence, I fear they are not sufficiently alive. In the case of "Cahill against Verner," tried before the Chief Baron last week, an action was brought to recover damages against the High Sheriff of Monaghan for alleged neglect of duty in not arresting a gentleman who, at the time the execution was put into his hands, was under my care, and in the last stage of consumption. My evidence was required to show the state of the gentleman's health and the possibility of arresting him. I was subpœnaed to appear before the Chief Baron on the 24th June last, and to attend court till the case should be disposed of. The trial was postponed from day to day, and from month to month, till the first day of the present month, when the case was tried, and a verdict found for the plaintiff. From the commencement to the termination of the proceedings, I was obliged to make six journeys to Dublin, a distance of fifty miles, and altogether spent eleven days about court awaiting the trial. When called upon to give my evidence, I applied, as I had often done before with success, for remuneration for loss of time, as well as for travelling and hotel expenses. To my astonishment, his lordship replied that a recent decision of the English judges, by which he must be guided, had ruled that medical men were not entitled to be treated differently from other witnesses, and that he could only allow me travelling and hotel expenses, of the exact amount of which I would be required to make an affidavit. I need scarcely descant upon the enormous injustice which such a decision is calculated to inflict upon the profession generally, and unless they are determined tamely to submit they should be up and doing. It can hardly be credited that the legislature, if properly informed, would refuse to remedy so flagrant a wrong affecting a class of men of such respectability and national importance as the medical profession. To illustrate briefly the evil in my own case: I was obliged, in the first place, to procure the assistance of a medical man to take charge, during my absence, of a very extensive and laborious dispensary district, and of a fever hospital, with between twenty and thirty patients in it. In the next place, it so happened that every time I went to Dublin, pending the trial, I was compelled to leave some private patient requiring daily attendance; on one occasion, an elderly lady with a most alarming attack of tonsillitis; on another, an old gentleman with extensive bronchitis; on another, a lady with apoplexy; and on the occasion of my last visit, three ladies were in hourly expectation of their confinement,—one was confined in my absence and was obliged to have other medical assistance. In fact, no compensation which a court would at any time have allowed would have repaid me, either for the pecuniary loss, or for the anxiety which I endured by my absence on these occasions; and I am determined, in future, to abide any legal consequences rather than obey a subpœna under similar circumstances.—I have the honour to be, sir, your obedient servant, Hans Fleming.

Carrickmacross, December 12, 1851.

ON THE VALUE OF LIFE ASSURANCE.

TO THE EDITOR OF THE MEDICAL PRESS.

Royal Exchange Assurance of London,
No. 8, Westmorland-street.

Sir,—Feeling that the welfare of the medical profession has at all times been a subject of interest to you, perhaps you will kindly permit me to gain access to them through the medium of your columns, in order to draw their attention to a subject of great importance, both to themselves, their families, and society at large; I allude to the matter of a family provision.

The annual reports of the Medical Benevolent Fund Society have brought so many melancholy instances of individual and family suffering under the notice of their brethren, that I feel it would be idle to occupy time in endeavouring to prove the generally-admitted principle of the duty and necessity which is incumbent on the profession (in common with others) to make suitable provision for those whom God has committed to them the charge of; it is one thing, however, to admit a principle, and another to put it in practice—here, no doubt, is the difficulty—here the question of how is it to be accomplished arises.

The community is not unmindful of the difficulties which the medical profession at large, perhaps more so than any other, have had to encounter for some years past, the depression of the times having obliged them in too many instances to be satisfied with ill-requited services, while in others they have been bestowed in the cause of charity; in such acts have they been called on to face fever and pestilence, probably at times when, physically speaking, they were least fitted to do so, and not a few have fallen beneath the foe; thus the fee books have not been filled, and family economy—aye, rigorous economy—has been imperatively necessitated.

Can we at such a time (say many) undertake the onus of future provision for our families, when we find ourselves hardly able for the urgency of present necessity? This, in my opinion, should be the incentive to the duty. Were a ship at sea to run short of provisions, think you would the commander be thought very sagacious, who, in the purport of a prolonged voyage, would give his crew the usual quantum, trusting to fortuitous chance to procure a supply? No: he would prudently impose present reduction, in order to reserve for future subsistence; and such, I take it, is very much the case of many of the profession at the present moment. Can any of them read the reports of the Society before referred to, and mentally witness the sad sad scenes therein detailed of the widow's nakedness and the orphan's hunger, and not be urged to the resolution that in some degree he will endeavour to preclude the removal of such harrowing unavailings?

And here I would advocate the peculiar adaptation of life assurance as a medium for family provision. Some of the profession are still deriving handsome incomes by their practice. They have families dependent on them. Have they provided? Probably they will reply, we are laying by annually of our surplus. That certainly is but prudent: but who has promised you a prolonged life? Can you undertake it for one year's existence? No: if called away, how would it be with those for whom you are now toiling? Why not, then, lay by of your surplus in a bank that will be prepared—be the call near at hand or more remote—to honour the draft with *ample* interest?

Others may not be so affluent in their means; to them I would say, measure your provision by these means, but do not relinquish the duty because you cannot complete it to the extent you would desire. Others, again, are struggling to push forward their families in decency, and endeavouring to uphold them in the scale of society to which they have hitherto been accustomed. This no doubt is praiseworthy. But if the difficulty be now so great, what must it be when the head that thinks and the hands that act for them, shall cease to exist? Will you be content to bequeath them to the cold hand of a world's charity? On you, then, would I the more urgently impress the necessity of making some provision, no matter how small. Do not leave those dearest to you totally unprovided for.

Doubtless I shall be accused of self-interested motives in writing this letter; probably there may be something of the kind in it, but I hope, that as one who has witnessed the safety afforded in the ark of assurance, I may take the liberty of impressing upon the profession the duty, without particularizing the channel through which it is to be accomplished. Of course I would support the claims of the highly honourable and ancient corporation which I have the pleasure to represent for a preference, more especially on the part of the profession, to whom they have at all times been most liberal; but my object is attained if I shall have succeeded in drawing the attention of many who, in the hurry of professional duties, have neglected to give the subject the consideration which it deserves.—I am, sir, your obedient humble servant, Thomas Trouton.

Dublin, December 12, 1851.

ADDRESS TO DR. FRY OF FERBANE, IN THE KING'S COUNTY.

The following flattering address has been presented to Dr. Fry by the subscribers to the Ferbane Dispensary. Such expressions of regard we place on record as evidence of the feeling entertained toward our brethren in the provinces:—

"Dear Sir,—The changes about to take place in the medical charities of Ireland, and the consequent closing of the Ferbane Dispensary, afford us the pleasing opportunity of recording our high sense and approval of your conduct as its medical attendant for twenty-six years, nearly from the time of its first establishment. During that lengthened period we have had every opportunity of witnessing your constant

and indefatigable attention to the duties of your office. You have been at all times assiduous and energetic, but especially in seasons of fearful epidemic and fever we have noticed your zeal and alacrity, and found that no increase of labour, or danger of infection—which at one period was near being fatal to you—ever relaxed your exertions in the conscientious discharge of your arduous and perilous duties. The calls of your suffering fellow-creatures ever received from you a prompt and humane attention. In the closing of our institution, it affords us gratification to know that our connexion with you will not terminate, but that the population of every class in our neighbouring district will continue to have your valuable services, and still be benefited by that medical skill and attention which we all have so long witnessed, and that some of us have personally experienced.

We pray your acceptance of the accompanying piece of plate, and hoping for your continued health, happiness, and prosperity in the practice of those duties, professional and social, which has gained for you universal respect as a physician and friend,—We remain, with much esteem, your sincere well-wishers,

H. King, Chairman; Rosse; J. G. King, J.P., D.L.; Francis Mooney, J.P.; James Alexander, Clk.; Robt. Lauder, J.P.; Joseph M. Daly, Clk.; Mark O'Ferrall, P.P.; John J. Frazer; Abraham Bagnall; Thos. Mulock; Thomas H. Mulock; John G. Collins, J.P.; Robert Delany; John D. Lauder; John Whitfield; Timothy Bagnall; Francis Royston; Harriet King; Jane King; Mary King; S. I. Lauder; Sarah F. Frazer; P. T. Klasen, C.E.; James Devery; Wm. Henderson; A. Galven, Secretary."

MORE SIGNS OF "UNIVERSITY" DECREPITUDE.

It is not without regret we feel ourselves compelled to revert to the subject of the School of Medicine of Edinburgh. But we proposed to ourselves a very serious and solemn duty and did not commence our ungracious task without the firm resolution of persevering to the end. That end must be the purification of the venerable institution from all the fraud and quackery which dishonours it. We have appealed to the appointed guardians of the place. Sorry are we to write our conviction that there is no hope in them. Some, conscious of their own feeble merit, are unwilling to make inquiry into the conduct of others; some, themselves perverted, love error for its own sake; all are deficient in that honesty of mind and energy of purpose which are necessary for success in any great work. Had they shown an absolute determination not to abide so great a scandal, its rectification would have been sure and immediate; but they denounced the evil, and then, good, easy men, sat down exhausted and satisfied with so vast an effort, thus giving countenance and credibility to all the allegations of their guilty opponent and accuser.

It is with much reluctance we inform the students there is no help but in themselves. But we know their honesty and their courage, and rely on them with perfect confidence. We have also much consolation in the thought that it is quite safe to act in this business. No student need fear the displeasure of his superiors. The latter are too much ashamed of their own helplessness and shabbiness. In their secret hearts they approve of that which they dare not imitate, and which, at all events, they dare not punish.

The case of the students is so just as to gather all mankind to their side. Who, indeed, but must feel indignation against men practising what they do not believe, and teaching what they do not practise; who have yet bound themselves by the solemn obligations of oaths, and by yet more binding professional and social ties, to teach science faithfully, and practise medicine truly, for the profit of their pupils and the welfare of their patients? Such dereliction of duties is so unmanly and so shameful as almost to exceed belief. Sorry are we to perceive it in a country which wraps itself up in the pharisaical pride of superior consolations.

The case of the students is one demanding instant reparation; it brooks no delay. What can be conceived more lamentable than the case of young men crowding to the university, eager for instruction, deeply impressed with the value of their profession, and the heavy responsibility of its duties, yet chilled at the very threshold of their studies with the information that their teachers deride the most approved doctrines of physic, and do not blush in other places to talk any crazy gibberish which will aid them in the pursuit of an ignoble and scandalous trade. If such things must continue, it requires no ghost to tell us that Edinburgh has "curbed her high career." We wonder, indeed, that Principal Lee could utter his sentimental commonplaces in the face of the assembly which met on the 1st of November, without hearing roars of laughter. If published, his address will surely move the scorn of all English readers.

We hear it whispered that the Faculty of Medicine allege they have done all in their power, and that in the obstinacy and indifference of the senators there is an irresistible obstacle. In answer, they must be told that we believe no such thing. On the contrary, we are well satisfied that, would they do their duty as becomes men convinced that it is one of paramount obligation with which there is no tampering, the resistance of senators and patrons would be feeble obstacles. But the medical professors must be prepared to play their part out to the end; they must be ready to close their class-rooms, and stop the whole business of teaching, till they are relieved from disgraceful colleagues, and the school purged of its dishonour. Their superiors would then soon learn that serious duties are not to bend before the pride of any pragmatical dogmatist, and that there is a power to compel unwilling men to the most distasteful tasks. The professors would do well, however, to consider the consequences of this plea. It is a maxim of English law, that there is no wrong without a remedy. If they put this case without the pale of society, men revert by right to the law of nature. It is not in this country, where resistance to unprincipled aggression is matter of doctrine, that such statements should come from authority. But we advise the students to be wiser than their teachers, to besiege both the senators and town council with their petitions, and to convey them with such circumstance and form as to call public attention both to the petition and the replies. Men who hunger for the bread of knowledge may surely complain of an Alma Mater offering them a stone. Infants have often corrected the faults of parents; and if the ancient jade is not reminded of her duty by her proper guardians, let her receive admonition at the hands of her children.—*Lancet.*

ROYAL COLLEGE OF SURGEONS, ENGLAND.

The following questions in pathology and surgery were submitted to the senior candidates for the Fellowship on the 4th instant:—

1. Describe the probable consequences, immediate and remote, of a severe blow on the testicle, and the requisite treatment.

2. Describe the forms of venereal sores, and state the course of symptoms, secondary and tertiary, exhibited by that form of sore to which the term *syphilitic* has been specially applied; mention generally the required treatment.

3. Describe the characters of scalds, burns, and frost-bites; and generally describe the treatment of the several stages of each.

4. State the circumstances which, in a case of alleged rape on a young female child, would induce you to give a decided opinion that the crime had been committed, and point out those occasional conditions of the parts which render a decision difficult.

5. Describe the causes, symptoms, and results of phlebitis, and state the treatment it requires.

6. Describe the characters and consequences of synovial inflammation of the knee-joint, acute and chronic; also its treatment.

The following, on the same subject, were submitted to the juniors:—

1. Describe the formation and progress of a true aneurism when not interfered with.

2. Describe the immediate and remote effects of an extraneous body which has slipped into the air-passages, and the treatment required under different circumstances.

3. Describe the effects of different wounds of the intestines, the prognosis, and reasons on which it is founded, and the treatment in each case.

4. Enumerate the different kinds of stone formed in the kidney and bladder. State which is the most serious, and why. Describe the symptoms and the treatment.

5. Point out the distinctive characters of phlegmonous, erysipelatous, diffuse, cellular, membranous, and carbuncular inflammation, their results and treatment.

6. Describe the mode of union of simple and compound fracture, and the circumstances which render the latter usually of more serious consequence than the former.

EXPENSE OF NEW MEDICAL CHARITIES.

(*From the Wexford Independent.*)

The very important position which the Poor-law Commission now occupies, both in a social and fiscal point of view, since the engrafting of the Dispensaries Act upon its machinery, will plead our excuse for so soon reverting to the operation of the measure which now interests so much the community at large, as ratepayers and the medical officers of charitable institutions, as government servants, placed in the highly important position of guardians of the public health, and general agents for carrying out in other ways than as mere dispensary doctors, the sanitary regulations which the Commissioners, by virtue of the powers given them, are called upon to execute throughout the district dispensary sessions. As we already ventured to prognosticate, the Board of Guardians of the Wexford Union maintained its character for intelligence and reasonable liberality, as evinced in the business-like manner with which they complied with the Commissioners order to map out the districts, and state the amount of salaries which they deemed a fair remuneration for the new and additional duties about to be entailed. In all cases the salaries were named at £100 per annum, and considering the nearly equal amount of duty to be performed, the average appears fair. The public need not feel at all alarmed at the apparent increase of taxation which that new rate will entail. We have already stated our opinion, that it will eventually be less than when the dispensaries were supported by the old, and we must add, dishonest, system of grand jury presentment, and without exactly pledging ourselves to the accuracy of our calculation, we would venture to say that 2¼*d.* per pound will cover all expenses under the present bill, allowing each dispensary to cost £140 per annum, against which we would place, as a set off, the discontinuance of vaccination expense, which averages £16 for each dispensary, and the county assessment struck off in all future applotments. And for this trifling, almost nominal tax, the public will have at its call a well-educated medical practitioner, supplied with every agent requisite to minister to the wants of the sick—*rich* or *poor*—under the surveillance of a vigilant local medical inspector (by the way we cannot see what the Poor-law Inspectors, *non*-medicals, have to say to the present question before the board)—and qualified to carry out in a most efficient manner the views of the government as to the general sanitary condition of the whole of Ireland. We have before us reports from all parts of the country relative to the salaries and duties of the medical men, but as in no instance do the proceedings appear to coincide with what bears upon the peculiarly well-constituted community of this our model county, we shall not trouble our readers with the discursive eccentricities of our far less enlightened neighbours. In some instances guardians have offered salaries to educated medical men not equal to that given by a noble chairman, Lord Castlemaine, to his own valet. However, the framer of the measure, Sir W. Somerville, provided against the possibility of this niggard system of remuneration, and accordingly left in the hands of the Commissioners, at whose head sits as high-minded a man as can be found in the ranks of any profession, the power of fixing the salaries, and therefore medical officers need not feel alarmed on the subject of their remuneration.

STATISTICS OF THE PARISIAN HOSPITALS.

The following figures will receive their full import, if it be recollected that the French capital contains, in round numbers, about one million of inhabitants. During the year 1850, there were admitted 60,007 patients into the *medical wards*; 54,372 were discharged, and 5804 died. On the 31st of December, 1850, 3673 beds of the same wards were occupied. The actual number of days spent in hospital has been altogether 1,417,714, which may be subdivided in the following manner:—Adult males, 604,265; adult females, 581,456; boys, 118,291; girls, 113,693. The mean mortality has been—For adult males, 10·28; for adult females, 13·37; boys, 8·71; girls, 8·45. The mean of the stay made in hospital was, for all sexes and ages, 22·58. For the same year, 1850, there were admitted into the *surgical wards*, 24,037 patients; 23,125 were discharged; and 1051 died. On the 31st of December, 1850, 1667 surgical beds were occupied. The actual number of days spent in the surgical wards were, in the aggregate, 688,023, which may be thus distributed:—Men, 411,136; women, 240,981; boys, 18,107; girls, 17,799. The mean mortality was:—For men, 25·52; women, 22·69; boys, 11·43; girls, 10·79. The mean of the number of days spent in the hospitals was 28·46. On the 1st of January, 1850, there were in the various asylums, 2047 insane patients; 6590 aged or infirm people; and 300 very old persons of both sexes in chartered institutions; total, 8937. During the year there were admitted 1245 insane patients; 10,510 old or infirm people, and 1048 very old persons in chartered institutions. During the same year there died 420 insane patients—mean of mortality, 7·37; 1060 aged or infirm people—mean of mortality 7·51; and 47 very old persons in chartered institutions—mean of mortality 7·51. On the 31st of December, 1850, there were left 2000 insane patients, 6731 old and infirm people, and 275 in chartered institutions. In the foregoing establishment, the number of days actually spent was 3,291,631, which may be thus divided:—Men, 1,357,148; women, 1,801,190; boys, 26,756; girls, 13,537; and 498,179 days for attendants. Sum total, 3,699,807 days. On the 1st of January, 1850, the number of foundlings being brought up by the charities was 13,631; on the 31st of December the number had descended to 13,559. In the course of the year 1849, 4133 children were abandoned, and in 1850 there were only 3952. The following figures express, in round numbers, the income and expenditure of the hospitals:—Salaries, £38,400; remuneration to physicians and surgeons, £10,500; sundries connected with officers and servants, £6400; book-keeping, £4000; pensions and donations, £6460; building repairs, £2000; taxes, £4000; flour, £26,500; wine, about the same sum; meat, £56,000; medicines, £20,000; fuel, £20,000; lighting, £5000; washing, £7000; bedding, £4000; linen, £10,000; clothing, £10,000. Total of ordinary expenditure, £572,000; decrease on the year 1849, £32,000. The mean expenditure for each patient is about 1s. 6*d.* per diem. On 31st December, 1850, there were 37,779 families receiving relief at home, these being composed of 22,884 men, 31,136 women, 17,126 boys, and 17,531 girls. Sum total of paupers, 88,677. The income of hospitals and charitable institutions is £600,000 a year, the sources of which are as follow:—House and landed property, £34,000; the hospital tax levied on theatres, concerts, and all kinds of public amusements, yielded £28,000; interest of stock, £72,000; total, £134,000. The remaining £466,000 are supplied by the municipal funds.

A LAWYER'S OPINION OF MEDICAL MORALITY.

An application was made to the Lord Chancellor last week for the payment, out of a lunatic's estate, of a fee of fifty guineas to Dr. Winslow, for his examination and report on the condition of a lunatic. In refusing the application, the Lord Chancellor remarked, that "in the present instance, as was likewise almost always the invariable practice, the medical man had reported in favour of the views of those parties who had employed him." It is with regret we find that one occupying the high position of the Chancellor has thus given expression, in a judicial capacity, to so illiberal an opinion on the conduct of medical witnesses. Surely his Lordship's experience and acquaintance, as Mr. Sergeant Wilde, with numerous eminent members of our profession, must have given him a better knowledge of medical character. A little reflection would, we are sure, enable him to perceive that, whether in reference to the case submitted to his decision, or to the general practice of respectable medical witnesses, the imputation conveyed in these remarks is as unfounded as it is untrue.—*Med. Gaz.*

MEDICAL CHARITIES' BILL FUND.

The Treasurer, Dr. Morrison, acknowledges the receipt of £1 each from Dr. MacCaldin, Coleraine, and Dr. Barr, Maghera.

Newry, December 22, 1851.

IMPORTANT TO PAROCHIAL SURGEONS.

A CASE of importance to parochial surgeons was tried before Mr. Sergeant Manning, Whitechapel County Court, for the recovery of 7*s.* 6*d.* for attendance upon one John Stokes at the request of the defendant. The plaintiff, Mr. Hart, resides in Union-street East, Spitalfields, and is parochial surgeon for the parish of Spitalfields; the defendant, Mr. Arnold, is a vestryman of the same parish, and a salesman in Spitalfields market. Mr. Hart's assistant proved as to his employer being sent for by the defendant, and to Mr. Arnold's using insulting behaviour towards Mr. Hart. Mr. Hart said that early on the morning of October 15, he was sent for to attend a man taken suddenly ill at, he understood, the defendant's shop. As soon as he had dressed himself, he went to defendant's house, and found that the man was at the Cheshire Cheese public house, where he went, and found he had broken a bloodvessel. He prescribed for him; and as defendant had sent for him, he looked to him for payment. He was a parochial surgeon, but cases like this did not come under his contract with the parish. The man had not an order from the relieving-officer, and he had to supply the medicine from his surgery. Mr. Arnold said he was informed that a man was dying, and that five or six people had been for Mr. Hart, who had refused to attend. He, as a vestryman, was entreated to send for him, upon doing which Mr. Hart came. He considered that as Mr. Hart was in the receipt of £120 a year from the parish, he had a right to attend to cases of such emergency as this. Had they waited for an order from the relieving-officer, the man must have died at once. It was not the money he begrudged, but the principle; and he certainly spoke rather freely to Mr. Hart, upon which he instantly sent in his bill, and appended to it, "Mr. Hart has understood that Mr. Arnold is unwilling to discharge this account, although responsible for it." He considered he was not responsible for it, and had a judgment of the Judge of the Clerkenwell County Court in his hand, where it was held that parochial surgeons were bound to attend to cases like this; and that the parties sending for a medical man were not liable for expenses incurred. The Judge said he was of opinion that defendant had made himself liable, but under the circumstances he should not allow any costs. Verdict for the plaintiff. To recover this 7*s.* 6*d.* plaintiff's assistant had been there all day, plaintiff part of the day; and the costs he is saddled with amount to 3*s.* It may be necessary to observe, that no medical claims are heard without the production of the certificate of qualification.

NEGLECT OF A PARISH OFFICER.—An inquest was held by Mr. Carter, at the Duke of Sussex, Gibson-street, Lambeth, on the body of Joseph Garland Saunders, aged seven years. The brother and sister of the child were examined, and it appeared that both parents were dead, and witnesses lived in a single room at 48, Gloucester-street. On Sunday their brother was taken ill, and his sister, who is 11 years of age, was sent to Mr. Beck, a parish surgeon, living in the Westminster-road, for some medicine, which was given to her, but without any label on the bottle. Another application had been made, when it was represented that the child was in high fever. The answer was stated to be, "Oh! if he has fever he will live long enough to obtain a parish order." Two powders were, however, sent. The child getting worse, an application was made to Mr. Beck by a relative, who said that if he attended to every child with a bellyache, he would have enough to do. The child died on Monday, but it was proved Mr. Beck had not been informed of the case. The coroner sent for Mr. Beck's assistant, and having read over to him what had been stated, asked why he had sent medicine out without a label, and had not informed his master of the case. The assistant, a flippant young man, said they never labelled bottles for parish patients; and if he had known that this was a case of emergency, he should have gone to it. He then coolly took out his watch to look at the time. The coroner and jury appeared indignant at this; and the former said, "You need not look at your watch, sir; this is not a case to be trifled with; their time was of no object." The foreman said it was the first time he had heard that bottles were not labelled for the poor: their lives were as valuable as the rich. The jury ultimately returned the following special verdict:—"We find that the deceased died from natural causes, but at the same time we deprecate the system of sending out to the poor medicine without being labelled; and we consider that there has been great want of care on the part of Mr. Beck's assistant in not having informed his employer of the case."

CASTLETOWNSEND DISPENSARY.

AT a General Meeting of the Subscribers, held by requisition, at the Dispensary, on December 9, 1851,

The Rev. CHARLES BUSHE, Rector, in the chair,

the following was unanimously agreed to:—

We, the undersigned Subscribers to the Castletownsend Dispensary, take the opportunity of our assembling together at this the last meeting of the said institution to express the high estimation in which we hold the character of Dr. HADDEN. We have had ample experience of the zeal, assiduity, and patience with which he has discharged the arduous duties of Superintendent of the Dispensary; and we can also bear our testimony to his ability in his general practice, we cannot therefore suffer him now to take his departure from amongst us, without expressing our sincere regard at the same, and assuring him that he carries with him the good wishes and respect of all classes of the inhabitants of the district; and we further express our hope that the Commissioners of Medical Charities will take his case into consideration, and appoint him to some situation commensurate with his talents.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D.,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.
☞ *Change of Proprietorship.*
BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of
THE ROYAL MEDICAL HALL,
beg particularly to state, that henceforth
THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,
will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,
BEWLEY, OWEN, AND CO.'S ESTABLISHMENT
embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,
of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 3, will be published, price Sixpence, free by post, each volume complete in itself,
Enlarged to twenty-four folio pages,
The First Number for 1852, of the
GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;
A Weekly Record of Rural Economy and General News.
The Horticultural Part Edited by Professor Lindley.

The Farming Part (under the Editorship of a Practical Farmer) treats of—

The Practice of Agriculture,	Management of Stock,
Agricultural Science,	Veterinary Science,
Animal and Vegetable Physiology,	Drainage,
	Irrigation,
Improvements in Implements, described by woodcuts whenever requisite,	Foresting,
	Road-making,
	Farm Buildings,
Better modes of Husbandry,	Labourers,
Results of Experimental Farming,	Treatment of Poultry,
	Agricultural Publications,
Growth and Rotation of Crops,	

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are
Weekly Calendars of Gardening Operations,
Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It, moreover, contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make *The Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive *record of facts* only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions: their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any Newsvender.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Twelve months, ...	£1 5 0
Six months, ...	13 0
Three months, ...	6 6

*** Orders to be addressed to Mr. HENRY BEAUMONT, 15, Molesworth-street.

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A.

(Continued from page 325.)

"Nutrition."

(The Generation of Fibrin.)

Hitherto my reader's attention has been directed almost exclusively to the contemplation of that physiological process or function termed *the process of generation or reproduction*. To afford a clear insight into the general principles upon which (as it appears to me) *that* process has been arranged has been the anxious object of my preceding communications. And wherefore, it may be asked, *such* object in connexion with the topic before us? *Why*, some of my readers perhaps may have said, dwell thus long in a series of papers of the avowed subject of the present, upon the nature of the *regenerative process?* What such intimate connexion can there possibly exist between the pathology of inflammation or of fever, and the process of generation or reproduction, as to warrant our attention's having thus long been directed to the contemplation of the latter inquiry in connexion with an investigation professedly having relation to the former?

Should such be the feeling of any who may have perused the foregoing remarks, I would, in reply to that inquiry, assure them, that until we have made ourselves familiar with the nature of the process of reproduction, to me it appears to be *impossible* that we could *ever* become acquainted with the true nature of the phenomena which occur in relation to the questions which more directly engage our attention,—until, I say, we have acquired a clear and comprehensive insight into the true nature of the regenerative process, as that process takes place *universally* throughout organic creation, I regard it as *useless*, inasmuch as I conceive it to be utterly hopeless, to search for the true explanation of the various phenomena which are observed to occur during the existence of what is termed *inflammatory action*. For what is *generation* or the process of *reproduction?* It is simply, in other words, the process of *living*. Yes to *live* is to *generate*; to *generate* is to *live*; and *living* and *generating* are, as I shall endeavour to make apparent to my readers, strictly speaking, *but one and the same process*. In order to see this more clearly, it will be desirable to contemplate for a moment the regenerative process as it takes place in the two departments of organic creation—that is, to review it first as it occurs in the vegetable kingdom; and secondly, as it takes place in animals. The function of the simplest conceivable vegetation we have already investigated, and have seen that it was to *generate* a plurality of vegetations of the same species as itself, and at the same time to *generate* an organized residual product. We have further seen that it was during, and alone during the period that such generation was *in progress*, that this simple vegetation, *together with* the materials out of which it generated these two classes of product, *conjointly* constituted a *living* vegetation. It was during, and alone during the period I say, *that the process of such generation was in actual progress*, that this simple vegetation, and what I have termed its specific stimulus, *conjointly* manifested those phenomena which are essential to constitute what we understand by a *living* vegetation. The process of *generation*, then, it is obvious, must be what in *this* vegetation *constituted* the process of *living*, inasmuch as such was the *sole and exclusive* process or function which *such* vegetation performed. A very little reflection will make it apparent to the reader that such is also the case with regard to *all* vegetations, it matters not how complex be the nature of their organization. The great physiological function which the most complex vegetation is designed to perform is—*to generate* (out of materials prepared for that purpose in a manner which we have already investigated) a plurality of the several *simple* organisms which enter into the composition of that vegetation, and at the same time *to generate* a proportional number of organized residual products, such, for example, as albumen, lignine, the various alkaloids, &c. A very little reflection, I say, will be sufficient to convince all of my readers that *every other process* or function which takes place throughout the entire range of vegetable creation, is merely subordinate or con-

tributory to this one process or function *of generation or reproduction.* Hence the process *of generation* throughout vegetable creation is one and the same thing as the process of *living*. The *effect* of this process is to elevate matter in the scale of organization, and hence, as I regard it, the propriety of defining "*living*" (in the vegetable world) to be—*the act of being elevated in the scale of organization.* To what extent the same is equally true with regard *to all animals and to man*, I shall now endeavour to point out to my readers, and shall attempt to show that the process of *living*, strictly speaking—that is, *in contradistinction* to what for perspicuity might with propriety (as I shall presently attempt to point out) be termed the process of *dying;* that the process of *living*, I say, is identically the same for *all living beings in existence*, and that such process is simply, in other words, the process *of generation or reproduction.*

Have my readers ever asked themselves *why it is* that during the entire period of his existence man requires to be constantly supplied with what is termed *nutritive matter? Wherefore it is*, in other words, that, *in order to continue to be a living being*, man must continue to be furnished with food? Doubtless they have frequently reflected upon this question, and in reply have perhaps answered themselves thus: Man requires food for *the nutrition* of the various structures which enter into the composition of his constitution. For the nutrition of his structures! and what is nutrition? What is it which *constitutes* the process of nutrition, and wherefore is there a *necessity* for such process? Have my readers ever seriously reflected on these questions, and have they satisfied themselves as to *what it is* which constitutes nutrition? If not, I would assure them that it is simply, in other words, *generation.* Yes, that process which, in popular language, is termed the process of *nutrition* is, in physiological language, the process of *generation or reproduction.* The process whereby the minutest conceivable muscular fibre, *individually and alone*, is generated by a solitary individual muscular atom (which affords an example of what is understood by the process of nutrition) is, as I shall presently endeavour to make apparent to my readers, identically one and the same as that whereby *all the various fibres, &c. &c.*, which are eventually to enter into the constitution of man, are *collectively or in union* generated by the *various* atoms which in combination constitute the embryo of man. The process in both instances is the process of *generation*, the sole distinction (as I shall shortly attempt to point out to the reader), being this—namely, that in the former case we have an instance of the generation of *but a single individual structure*; in the latter, we have an example of *the simultaneous generation of several. This* process was essential to render the embryo of man a *living* embryo; *this* process it was which *constituted* that embryo a *living* being; and *then* this process was termed the process of *generation. This* process was further essential to render that embryo become a fœtus, a *living* fœtus; *this* it was which *constituted* that fœtus a *living* being; and *then* it was termed the process of *growth.* And finally, *this same process* was equally essential to render that fœtus become a man, a *living* man; *this same process* it was which *constituted* man a *living* being, and *then* it was termed the process of *nutrition.* Yes, in the *fully-developed man*, the *re*-generation of his component constituents is equally as essential to the continuance of man as a *living* being, as in the simplest vegetation, in the embryo and in the fœtus the *generation* of certain products was essential to constitute that vegetation, that embryo, or that fœtus a *living organism.* If, then, the process of the regeneration of his component constituents be essential to constitute man a *living* being, it is obvious that in order to be informed how the process of living is proceeding in man, we must learn how the process of regeneration is proceeding in his component constituents. That the process of regeneration as it is proceeding in the component constituents of an organism, constitutes what in popular language is termed the process of nutrition, I shall now endeavour to point to my readers, and it must be obvious that without a knowledge of the nature of what is termed "*the nutritive process,*" it would be utterly hopeless to seek for the true explanation of the phenomena which occur during the existence of what are termed Inflammation and Fever. I say *hopeless*, inasmuch as a perturbation or disturbance of the normal process of nutrition occupies a most conspicuous and important position among those phenomena. It hence becomes apparent, if such statements be correct, wherefore it is that, antecedently to acquiring a knowledge of the nature of the phenomena which occur during the existence of inflammatory action, it is *indispensable* that my readers should have a clear and comprehensive acquaintance with the nature of *the regenerative process.*

That in the process termed "*nutrition*" (as it takes place in the component *simple* organisms or organizing atoms, of which the *compound* organism man is composed), we have nothing but the process *of generation*, as detailed in my preceding communications, to investigate, and consequently no new physiological process to inquire into, I shall now endeavour to make apparent to my readers. The consideration of this subject brings us directly to that of the questions at present before us—namely, *how* and *where* is fibrin generated; and secondly, *how* and *where* when generated is fibrin appropriated to the purposes of nutrition?

In order that I may be clearly understood upon this topic, my readers will have the goodness to recal to their mind the supposed combination of three imaginary organizing atoms to which I directed attention in one of my former communications, with the twofold purpose of illustrating what I meant by the expression *compound* organism, and of pointing out the nature of the relation which I conceive to subsist between the successive links of what I have termed the chain of progressively ascending organizing atoms—I allude to the imaginary compound organism which I supposed, for the purpose of illustration, to be formed by the union of three individual organizing atoms, selected respectively from the first three species of organizing atom in succession—namely, one of what I termed the first, one of the second, and one of the third species of atom. We there saw that the specific function of the *first* species of atom in that compound (having regenerated a plurality of its own type) was to generate out of unorganized or mineral matter, an organized residual product which could stand in the relation of *specific stimulus* to the second species of atom in that compound; or in other words, which could arouse or stimulate that second species of atom to the discharge of its specific function *of organizing*—in other words, of *conferring* (increased) *organization.* I shall now, in order to be as simple and as intelligible as possible to all of my readers, in place of the words *specific stimulus* (which, from the function it is destined by Nature to fulfil, appears to me to be its appropriate appellation), I shall, I say, in place of the words *specific stimulus* as applied to that residual product, substitute the word *nutriment*, which, as being more familiar, may, to some of my readers, perhaps, convey a more definite meaning. The function, then, of the *first* species of atom, in the imaginary compound organism to which I refer, was to generate (out of unorganized or mineral matter) an organized product which could stand in the relation of what is termed *its nutriment* to the second species of atom in that compound. The function of the second species of atom in that imaginary compound was to generate (out of the organized residual product *or nutriment* prepared for it by the first) a second (or more highly organized) species of organized residual product which could stand in the relation of what is termed *its nutriment* to the third and last species of atom in that compound. And finally, the function of the third (and highest) species of atom in that imaginary compound was to generate (out of the organized residual product *or nutri-*

ment prepared for it by the second) a third (or still more highly organized) species of organized residual product.*

Let us now, in place of the three imaginary atoms comprised in the composition of that imaginary compound organism, substitute three atoms which are no objects of imagination, but whose existence admits of the clearest demonstration. Three atoms, too, which follow each other in the direct order of succession supposed with regard to the component atoms of that imaginary compound—that is, three *simple* organisms or organizing agents which stand towards each other in a relation identically analogous to that in which stood the three imaginary atoms comprised in the imaginary compound we have just been contemplating. I allude to those three *simple* organisms or organizing agents which generate respectively the three organized residual products known to us by the names *albumen*, *fibrin*, and *muscular fibre*. These three organisms I shall for perspicuity call the albuminous, the fibrinous, and the muscular atom. What is the specific physiological function respectively of each of these atoms? It is this—namely, the function of the *first* of the three, or of the albuminous atom, is to generate (out of matter provided for that purpose by Nature) that organized residual product which we call *albumen*, which albumen is designed by Nature to stand in the relation of specific stimulus *or nutriment* to the second or fibrinous atom. The function of the *second* or fibrinous atom is to generate (out of the albuminous residual product or nutriment prepared for it by the albuminous atom) a *more highly* organized residual product named *fibrin*, which fibrin is designed by Nature to stand in the relation of specific stimulus *or nutriment* to the third or muscular atom. And finally, the function of the *third* or muscular atom is to generate (out of the fibrinous residual product or nutriment prepared for it by the fibrinous atom) *a still more highly* organized residual product named *muscular fibre*, which muscular fibre being placed *at the top or summit of its branch* in the organizing chain is designed by Nature to fulfil *one or both* of the two following functions—namely, either to perform *some specific physiological function peculiar to itself* (viz., *contraction* in the case of muscular fibre) within the organism in which it has been generated; or else it is designed to stand in *some relation* (viz., in the case of muscular fibre, the relation of nutriment, for example, to carnivorous animals) to something distinct and apart from the organism in which it has been generated. For one or both of these functions, it appears to me that every organized residual product, physiologically positioned similarly or analogously to muscular fibre, must of necessity have been destined.

Such is an outline of the relation in which those three *simple* organisms stand towards each other; such is an outline of the functions those organisms are designed to fulfil. I would solicit my reader's serious attention to their contemplation. I would urge on him to make himself familiar with the operations of those three simple organizing agents, and he shall have acquired an insight into the nature of *all* the great physiological operations in Nature Yes, I say *all*, inasmuch as in the functions of those three granules, conjointly with those of the products which they generate, we have, as I regard it, presented us an example of each of the great physiological operations which takes place throughout *the entire of organic creation*. We have, I say, as I regard it, therein disclosed to us an example of the *nature* of each of the successive steps in that *circle of changes* which is uninterruptedly in revolution from the mineral to the vegetable, from the vegetable to the animal, and from the animal again to the mineral world. That *circle* wherein we see—1st. The organizing of *unorganized matter* to take place in the *vegetable* kingdom. 2nd. The elevation of the *same matter* (thus organized) in the scale of organization to take place in the *animal* kingdom. 3rd. The appropriation of the *same matter* (thus elevated) to the requirements of the animal organisms *whereby* such organized matter is *of necessity reduced or degraded* in the scale of organization, and eventually again becomes *unorganized matter*; and finally, the *re*-organization of *the same* unorganized matter (thus reduced) again to pass through the same ascending succession of changes, and thus constituting a circle in perpetual rotation. In the functions of the three granules before us, together with the function of their products, we have, I say, an example of the *nature* of each of these changes. Let us, then, examine those functions more closely,—let us trace *unorganized or mineral matter* from its departure from the unorganized or mineral world in its passage through the two departments of organic creation,—let us follow it step by step during its ascent in the scale of organization till *that same mineral matter* has eventually become *muscular fibre*,—let us see that muscular fibre on the discharge of its physiological function *depressed or degraded* in the scale of organization, and eventually reduced again to the condition of *unorganized or mineral matter*, and what shall we have done? We shall have done this: *We shall have passed in review the complete circle of the physiological phenomena which is in rotation throughout the entire of organic creation, the complete circle of changes which gives development to all existing organic phenomena,*

* But what is the design or object of this *third* species of organized product? For the fulfilment of what end in Nature has provision been made for *its* generation? What physiological function, in a word, has *this* organized residual product been designed to perform? The reader will be at no loss to recognize the importance of this inquiry. He will at once perceive that this *third* species of organized product is differently positioned as regards its physiological relations from the products generated by the first and second species of atom in the above imaginary compound. He will, I say, observe that the organized residual product generated by the *third* species of organizing atom (namely, the *highest* species supposed to exist in the constitution of the organism under consideration) is in its physiologieal relations altogether differently circumstanced from the residual products generated by the other two species of atom in that compound. In the imaginary compound organism which I have selected for consideration, it is obvious that the residual product generated by the *third* species of atom cannot by possibility stand *in any relation* (either that of nutriment or other) to any atom of the *fourth* species *comprised in the constitution of the compound organism in which that product has been generated;* inasmuch as no atom of the fourth species exists in that compound, the *third* being the highest species supposed to enter into its constitution. Now, every organism in existence, whether simple or compound, must obviously, after the discharge of its physiological function, have at least *one* (and compound organisms, as we shall presently see, have frequently *several*), every organism, I say, must have at least one residual product exactly similarly or analogously circumstanced. Every residual product similarly or analogously circumstanced affords an example of one of two things—namely, it is either the *highest species* of organized product contained within the organism in which it has been generated, as in the case we have just been considering; or else it is a residual product generated by an atom placed at what I have termed *the top or summit of its branch* in the organizing chain (see Note, p. 162). In a word, it is a product for which there does not exist *within the organism in which it has been generated* an organizing atom towards which it can stand in the relation of nutriment. That residual products so circumstanced *are* generated admits of no question, it consequently remains for us to determine what has been Nature's design in their generation; or in other words, for the fulfilment of what function were they formed. There are but two ways in which to me it appears *to be possible* that Nature could have designed that any so circumstanced residual product should be disposed of—that is, in *one or both* of the two following ways—namely, it must have been designed to stand in some relation (whether it be that of nutriment or other) to something *distinct and apart from the organism in which it has been generated;* or else it must have been designed to perform *some specific physiological function peculiar to itself* within the organism in which it has been generated. As an instance of the former, certain products may be generated *by* the vegetable *for* an animal creation; and as an example of the latter, nervous, muscular, vascular, glandular, &c., structure, are generated within the organism man. I trust should there be any of my readers to whom I may not convey myself clearly, that they will understand me when I shall have illustrated the foregoing statements, which I shall do in the text.

including the phenomena of living *and of* dying. In selecting *muscular fibre* to illustrate the nature of what is termed "*the nutritive process*," as also of physiological operations in general, including the phenomena of *living* and *dying*,—in selecting muscular fibre, I say, for this purpose, I would say "*ex uno disce omnes*," for the process is the same for *all* structures; and my readers may at will substitute for the words "*muscular fibre*" in the following observations any one of the following expressions—namely, cerebral matter, nervous structure, glandular structure, &c., which are all *generated* or caused to *live*, and *degenerated* or caused to *die* in a manner in every respect identically analogous.

The following is the succession of changes (including what is popularly termed "*the process of nutrition*," the process of *living*, and the process of *dying*—in a word, giving development to organic phenomena *generally*) to which I have solicited my reader's attention.

In the vegetable kingdom, inorganic or mineral matter has been raised (in a manner which I have already attempted to investigate) from its *unorganized* condition to that of the *simplest species of organized* matter; that is, to the condition of matter possessed of *the humblest or lowest degree of organization*. This elevation has been effected through the agency of the *simplest species* of organizing agent, which agent (or organizing atom) having generated from a portion of that organized matter a plurality of its own species, and having left another portion thereof as an organized residual product of the humblest or simplest species, is itself reduced to the condition of unorganized or mineral matter. The albuminous atom then discharges its specific function of organizing upon the organized residual product thus prepared for it by one or more humbler species of atom; radiates thereon its own influence centrifugally and in every direction, thereby surrounding itself with an envelope of this organized matter; raises that matter still higher in the scale of organization, and eventually disposes of it as follows—namely, 1st, regenerates a plurality of the albuminous atom (competent at any future period to discharge a similar function); and 2ndly, leaves an organized residual product to which has been given the name albumen, which is capable of standing in the relation of specific stimulus or nutriment to a higher species of organizing agent as, for example, to the animal fibrinous atom. Such is the entire function of the albuminous atom, and having discharged this function it is itself reduced to the condition of inorganic or mineral matter. The reader will please to bear distinctly in mind that this process takes place *in the vegetable kingdom*. When the albumen thus generated by a *vegetable* organism is presented to the *animal* fibrinous atom, this latter discharges its specific function (of organizing) in a manner identically analogous to that in which the albuminous atom had just discharged a similar function. But *where is the situation* of this fibrinous atom? where is the *animal* fibrinous atom *situated?* Not in the vegetable organism in which we have seen the albumen which is designed as its nutriment has been generated, but in an organism distinct and apart from that vegetable—namely, in *an animal* organism. But *where* in that organism? for this, too, is a matter of the utmost importance, *where or in what part* of the human organism is the organizing agent which generates the fibrin of the human blood situated? *It is*, and I would desire to impress this forcibly upon the mind of my readers, it is *within the human vascular parietes*.*

Within the vascular parietes! How, then, does albumen come in contact with that atom? How or by what means is albumen conveyed from external creation *to the interior* of the animal vascular system? By what *agency or force* is that substance caused to pass the parietes of the vessels? What, in a word, is *the cause* of what is termed *its absorption?* This is an inquiry of no inconsiderable physiologi-

* It is scarcely necessary for me to remind my readers that whenever fibrin (or muscular fibre) constitutes the food of an animal, *it is reduced to the condition of albumen* (in the alimentary canal) before it enters the parietes of the animal vascular system. Why is this so? There are several reasons for such being the case, but there is but one to which I am desirous of now directing the readers' attention, and it is this: No *physiological* provision has been made in the animal organism for causing the attraction of *fibrin* from the alimentary canal *to the interior of the animal vascular system* (I can assure my readers that the process termed "*endosmosis*" is utterly incompetent to account for the phenomena of organic absorption). When, however, on the other hand, *albumen* (which we have already seen generated by a vegetable organism) is brought (in the animal alimentary canal) *within the sphere of the attraction of the fibrinous atom* (which latter is situated *within* the parietes of the vascular system), when, I say, *albumen* is brought within the sphere of the attraction of the fibrinous atom, a physiological provision *has been made* to cause *its* entrance into the *interior* of the vascular system. For when the albumen is thus placed within the sphere of the attraction of that atom, the result of the operation of that force of attraction *must be to draw that albumen into the interior of the vessels*. I trust I have been distinctly understood in the above statements; if not, I would beg of my readers to consider these *facts*—namely, it admits of no question whatever that a force of attraction *does* exist between albumen and the organism which generates fibrin; an attraction analogous (as I have already endeavoured to make apparent) to that subsisting between an acid and a base; it is equally certain that if that force exists it *operates;* and it is further equally certain that the two substances between which it acts are separated from each other by the vascular parietes, while it will not be questioned that those parietes possess no free openings or perforations which could admit the passage of an organizing agent. Hence a complete physical barrier is presented to the passage of the fibrinous atom in its *granular* form in the direction of the albumen; that is, in other words, it is *physically impossible* that the fibrinous atom could (under normal circumstances) escape the barrier of the vascular parietes. The result, then, of the operation of that force of attraction *must* obviously, as it appears to me, be to draw the albumen (which my readers are well aware exists in the alimentary canal in the form of *fluid*) in the direction of the fibrinous atom which, as I have above observed, is, in other words, into the *interior* of the vascular system. Hence the necessity for *albumen* to exist in the *fluid* condition in order to admit of its *entering* the vascular system; hence, too (as we shall presently see to be the case), the necessity for *fibrin* also to exist in the *fluid* condition in order to admit of its *escaping from* the vascular system.

Under the terms "*vascular system*," as employed in the foregoing remarks, my readers will observe I include *the entire system of vessels* comprehending lacteals, lymphatics, arteries, capillaries, and veins, which all open into each other, but which have *no open communication* with external creation.

My readers will please to bear distinctly in mind that in my observations with regard to albumen and fibrin, I refer exclusively to the fibrin generated in the *human* organism, with which alone we are at present concerned. Vegetable albumen admits of being further modified in the vegetable kingdom, but with that at present we have nothing to do. My sole object here is to attempt to point out the nature of the relation in which the three kingdoms of Nature—namely, the mineral, the vegetable, and the animal world, stand towards each other with regard to what is termed "*the nutritive process*."

The reader will also have the goodness to observe that I have not considered it desirable at present to stop to investigate the question whether *any additional element* besides albumen is required for the generation of *animal* fibrin, as also whether *any additional element* besides fibrin is required for the generation of muscular fibre. I have purposely omitted these considerations at present, for the purpose of simplicity, and to avoid embarrassing the reader with regard to *general principles*, to which, on the present occasion, I am chiefly desirous of directing attention. I have further considered that it would be undesirable, in connexion with the subject before us, to stop to inquire into the nature of the changes which *vegetable albumen* undergoes in the animal alimentary canal antecedently to its entering the animal vascular parietes. Upon what are termed "*the processes of chymification and chylification*;" as also upon the *specific function* of lacteals and lymphatics, I trust at some future period to have the privilege of again meeting my readers, but the question at present before us is, *how* and *where* is fibrin generated?

cal importance, I shall attempt a reply to that inquiry, the answer to which appears to me to be this: When the albumen which we have seen generated by a vegetable organism is transferred to the animal alimentary canal mark how it is circumstanced in that position. It is there placed *within the sphere of that attraction* which we have already seen to exist *between albumen and the fibrinous atom.* These two substances, however (namely, albumen and the fibrinous atom), though reciprocally attracting each other, *are separated* by the vascular parietes, which parietes *are devoid of perforations or free openings.* Now the latter of these two objects (between which this attraction exists), that is, the fibrinous atom, being of a *granular* constitution (that is, existing in the form of *a granule),* is physically *incapable* of passing through the parietes of the vessels, and therefore *must,* notwithstanding the operation of this attraction, still continue to retain its original position; that is, must still remain *in the interior* of the vascular system. Not so, however, the albumen. This substance, which is placed at the *external surface* of the vascular parietes (namely, in the alimentary canal) exists there in the form of *a fluid;* and in that fluid condition it can pass with facility the parietes of the vascular system. The result, then, as it appears to me, must be this—namely, by the operation of that force of attraction which exists between albumen and the fibrinous atom (namely, the attraction which Nature has placed between *every* organizing agent and its *specific stimulus);* by the operation, I say, of this force of attraction (conjointly, no doubt, with forces of another description into the nature of which it does not at present concern us to inquire), by the operation of this force of attraction, the albumen which exists in the alimentary canal *must be drawn into the interior of the vascular system,* inasmuch as the fibrinous atom *cannot* be drawn in the opposite direction. By the operation of this force, the albuminous residual product must, in a word, *be absorbed.* Such appears to me to be the rational explanation of the phenomena of *organic* absorption, or of the transit of *organic materials* from external creation to the interior of the animal vascular system. It remains for us now to inquire what becomes of that albumen when it has found its way into the interior of the vascular system?

When the albumen *has entered* the animal vascular parietes it there meets the fibrinous atom, to which it stands in the relation of specific stimulus (or nutriment); the consequence is that it at once arouses that atom to the discharge of its specific physiological function of organizing, or conferring organization (that is, of conferring upon that albumen an *increased* or higher degree of organization, or raising it in the scale of organization); converting that albumen, in a word, into a substance from out of which may be generated *animal tissues. Within* the animal vascular parietes, then, or in other words, *within the circulating fluid,* the fibrinous atom radiates its influence centrifugally, and in every direction, upon the albumen prepared for it by the albuminous atom. The result is, that this fibrinous atom in the first instance surrounds itself with an envelope of that albuminous product, thereby constituting a "*nucleated cell;*" then raises that albumen still higher in the scale of organization, and eventually disposes of it thus—namely, 1st, it regenerates a plurality of the fibrinous atom, which atoms (in the form of *microscopic granules)* it deposits in the circulating fluid to constitute a portion of what is termed "*the liquor sanguinis of the blood;*" and 2ndly, it leaves an organized residual product to which we give the name *fibrin* (designed to stand in the relation of specific stimulus or nutriment to the muscular atom), which fibrin it also deposits in the circulating fluid to constitute another component of the liquor sanguinis of the blood.

Such is the *entire* function of the fibrinous atom, and having completed that function it is itself reduced to the condition of unorganized or mineral matter, which forms a third constituent of the liquor sanguinis of the blood.

Have my readers ever examined the liquor sanguinis of the blood under the microscope? Doubtless the majority of them have. And what have they seen? I shall endeavour to inform them. They have seen minute granules *free,* that is, independent of an envelope; they have seen granules *partially enclosed* within a membranous envelope; they have seen *completely enveloped* granules constituting "*nucleated cells;*" they have seen fragments or shreds of a membranous nature; and finally, they have seen saline and amorphous materials. They have seen, in a word, the fibrinous atom *before it had commenced the discharge of its function;* they have seen the same atom with its nutriment *as that function was proceeding;* they have seen that atom (in the form of inorganic or saline materials) when its function had been completed; and finally, they have seen *the results of the function of that atom.* This (as it appears to me) is what they *must* have seen, for this, as I regard it, is what (for the most part) *constitutes* the liquor sanguinis of the blood.

Thus, then, we have determined the reply to the former portion of our present inquiry—namely, *how* and *where* is fibrin generated? The answer to that question is this: It is generated *by an organizing atom* out of albuminous matter; and it is generated *within* the parietes of the vascular system. I would urge on my readers to convince themselves of the truth of these two facts; facts of the utmost pathological as well as physiological importance—namely, 1st, that fibrin is generated, and can alone be generated, *by an organizing agent;* and 2ndly, that the generation of fibrin *normally* takes place *within* the parietes of the human vascular system.

In my next communication I shall proceed to the consideration of the second part of the present inquiry—namely, *how* and *where,* when generated, is fibrin appropriated to the purposes of nutrition.

(To be continued.)

PROCEEDINGS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Mr. Hodgson, President.

COMMUNICATION BETWEEN THE STOMACH AND COLON.—INTUSSUSCEPTION THROUGH THE ILIO-CÆCAL VALVE.

By Mr. Jones of Carnarvon.

Case 1.—A boy, five years old, one of a healthy family, was first observed to be unwell on the 10th of December, 1850; there was derangement of the stomach and bowels; patches of erythema nodosum appeared on the arms and legs, accompanied by languor, debility, and loss of appetite. These symptoms continued more or less during the whole month, and the child lost flesh. On the 31st, violent pain in the belly, accompanied by vomiting, occurred, and for two days there was vomiting of a dark-brown fluid, having an offensive smell, like that of pus from an indolent, ill-conditioned abscess. The vomiting ceased, but frequent attacks of pain, and a constipated state of bowels, continued. The food taken did not nourish the child; emaciation was progressive, the abdomen tympanitic, and there was frequent loud rumbling in the bowels; pressure gave relief. On the 20th of February vomiting returned, and lasted at intervals until the 10th of March, when diarrhœa supervened, and both pain and vomiting ceased. The diarrhœa continued and appeared to give relief; the child took food well and slept comfortably but did not gain flesh or strength. About the middle of May the bowels again became torpid and the appetite failed. A mild aperient caused great pain, without acting upon the bowels, but vomiting of stercoraceous matter ensued. During June and July the same state continued; there was no pain, but vomiting returned every second day unless the bowels acted. Before relief was obtained by the act of vomiting he was always languid and oppressed, but for some time afterwards he was more cheerful, and was able to take food with appetite, and did not reject it. Medicine always caused vomiting. On the 2nd of August he died exhausted. The body was much emaciated; the abdomen distended; the colon dilated to twice its natural size, forming several coils, and appeared

to occupy the whole cavity; its peritoneum was injected with some patches of ash-coloured discoloration, and some lymph adhered to it; the stomach was small, and contained some dark thick fluid; there was an adhesion between it and the transverse colon, and an opening allowing the passage of the finger from the one to the other; the small intestines were short and contracted; the colon contained some yellow matter, like that which had been vomited, and some scybalæ; the mucous membrane of the gut was healthy; the rectum empty; the other organs presented nothing very remarkable.

Case 2.—A man aged 37, of spare habit and delicate appearance, had suffered for several years from indigestion, occasional vomiting, and habitual constipation. On the 22nd of October, 1851, a dose of rhubarb, which acted but little upon the bowels, caused much pain, and this was followed by vomiting. A pill of calomel and opium, and afterwards calomel combined with purgatives; saline aperients in different combinations; leeches, embrocations, and enemata, were employed without any effect upon the bowels. On the 30th, the vomiting became stercoraceous, with relief to the pain; the tongue became clean, and he was able to take food. A pill of five grains of calomel and one of opium was now given every night, and frequent enemata were administered, but no other medicine. The patient lingered until the 6th of November, but little change in the symptoms having been observed. No blood was passed by stool or vomited; the urine was abundant and of natural appearance. In this case there was intussusception of the ilium through the valvula coli. The colon was quite empty, but the small intestines contained liquid fæcal matter, and there was a small quantity of the same matter in the stomach.

Dr. Watson said that the paper having been introduced to the notice of the Society by himself, and as the author was not present, he might perhaps be expected to make some remarks upon it. The points of interest in the communication were not, perhaps, very remarkable, but he thought that they were sufficiently important to entitle it to be read to the Society. The first case was an instance of a kind of lesion not, he believed, very uncommon, consisting of a communication between the stomach and the transverse arch of the colon, in which the matter was retained, and subsequently vomited. Dr. Abercrombie had detailed a similar case, and others were on record. Dr. Jones had formed a theory as to the origin of the disease, and had fancied that the affection of the bowels was the result of a metastasis of erythema nodosum from the skin. This idea was not very unreasonable when we took into consideration the translations of morbid action which presented themselves to us. In the second case there were one or two points of interest respecting which he should be glad to hear the experience of members. The preparation, he regretted to say, was not present, but it would be found, if examined, that it was a complete case of intussusception, the lower part of the ilium being invaginated into the commencement of the large intestine, so that nothing could possibly pass through it. Yet the matters vomited consisted of unmistakable excrement, having all the characteristics of human ordure. He could speak from personal examination, a portion having been sent to him in a phial, which unfortunately had been broken in its passage through the post (laughter). He did not know whether it was a point definitely settled by physiologists as to what exact part it was at which the refuse of the food became changed into pure excrement; it was, however, generally reckoned that this change took place in the large intestines; but in this case it was clear that the excrement could not have come from the large intestines, seeing that the obstruction was complete; it must therefore have been formed in some portion of the small intestines. Another point in the case was deserving of mention. It had happened to him, as it must to every one who had been as long engaged in practice, to see many fatal cases of intussusception; but he had no recollection of any case in which there was not a passage of blood per anum. So important was this, as a diagnostic mark of this peculiar form of obstruction, that in doubtful cases he had been in the habit of regarding it as decisive in the removal of the difficulty. Now in Mr. Jones's case no such symptom was observed. It was interesting to notice, also, the large quantity of water which was made during the obstruction; a point which Dr. Barlow had shown to be of importance as helping us to determine whether the obstructions were high or low in the bowels. These were the points in the case which Mr. Jones thought of interest.

In answer to a question from the President, Dr. Watson replied that the quantity of water evacuated in cases of obstruction of the bowels, had been shown by Dr. Barlow to indicate the *seat* of the obstruction.

Dr. Barlow rose and said that perhaps he might be allowed to add his experience on the point which had been referred to by Dr. Watson in connexion with his name. The opinion he had formed on a number of cases which had come under his observation. In several cases in which the obstruction was in the duodenum, he had found that there was positive suppression of urine; and in one case no urine had been passed for the space of five days This occurred in Guy's Hospital; and fearing that the urine might be retained, a catheter was passed, and only about a tablespoonful of urine was drawn off. The patient, a boy, lived two or three days longer; and after death, the duodenum was found contracted by a band of false membrane. In another case in which the obstruction was situated in the sigmoid flexure of the colon, and in which constipation existed for ten or twelve days, the patient voided a large quantity of urine. The quantity of the urine was less marked when intermediate parts of the intestine were obstructed. In a case of volvulus low down in the ilium, there was a fair secretion of urine. When the obstruction was low down, it would generally be found that much urine was secreted. He recollected a case similar to one of those mentioned in the paper, in which it was suspected that poison had been administered; a little blood was passed per anum, and there were many of the abdominal symptoms of poisoning by a mineral. The stomach, with a perforation in it, and the intestines, were brought to him. Before going into the case, he said, how was the urine? and the answer was, that for forty-eight hours there had been a fair quantity. How were the evacuations? There was blood passed. Now, in this case there was found intussusception of the ilium into the colon, and the perforation of the stomach was regarded as a post-mortem effect. The case was interesting, as illustrating two points in the diagnosis of these cases; first, in regard to his theory respecting the quantity of water, and secondly, with regard to the evacuation of blood from the anus as indicative of intussusception. Unless urgent sickness came on, when the obstruction was low down in the small intestines there would be a moderate quantity of urine secreted; when the obstruction was in the large intestines, as, for instance, in the sigmoid flexure, the urine would be copious; when it was high up in the small intestines, there would be almost suppression of urine. He referred to a case in which there was acute sickness and suppression of urine, giving rise to the suspicion that there was disease of the kidney. The disease, however, after death, was found to be situated in the duodenum.

Mr. Hancock inquired if, in the case mentioned by Dr. Barlow, in which the suppression had lasted for many days, the boy had the usual constitutional symptoms of suppression?

Dr. Barlow replied that he had, to a certain extent, a condition of the nervous system which indicated suppression—that quiet kind of stupor which Dr. Addison had pointed out as one of the signs of suppression.

Mr. Hodgson referred to a theory published many years ago, he believed, by Sir Everard Home, by which it was endeavoured to show that there existed some more direct communication between the upper part of the alimentary canal and the kidneys, than through the general circulation. Perhaps Dr. Barlow was acquainted with the hypothesis,

and considered that when obstruction existed in this situation, by preventing fluids from passing thus directly from the stomach or duodenum to the kidneys, it caused suppression of urine. He must, however, observe, that as far as his experience went, obstruction of the duodenum from organic disease was very rare, excepting at the pyloric orifice; and in pyloric obstruction, he had not observed any affection of the secretion of urine; nor had he where the obstruction was situated lower down in the intestinal tube, as in hernia, stricture, or other conditions producing obstruction either of the small or large intestines.

Dr. Barlow had formed a theory on the points he had mentioned. When the obstruction was high up, absorption was interfered with, so that little flowed into the system, and consequently little flowed out.

ALKALESCENCE OF THE URINE IN SOME CASES OF DISEASES OF THE STOMACH.

By H. Bence Jones, M.D., F.R.S.

In the *Philosophical Transactions* for 1845 and 1849, the author states that alkalescence of the urine may arise from fixed alkali, and may occur when the health is slightly, if at all, affected. In the present paper two cases of alkalescence of the urine from fixed alkali are recorded; the patients had suffered from pain in the stomach, and almost daily vomiting, for many years; and sarcinæ ventriculi were found in the vomited matter. The first patient was aged 46, and had suffered more or less for fifteen years before he was admitted into St. George's Hospital. The following may be taken as an example of the variations of the reaction of the urine:—October 4th: Early in the evening, before vomiting, the urine was acid to test paper, and gave a plentiful deposit of urates. Later in the evening, before he vomited, the urine was also acid. At eleven p.m. he vomited three pints of intensely acid fluid; the urine passed soon afterwards was alkaline from fixed alkali, and was cloudy from a deposit of earthy phosphates. At one a.m. the urine was rather less alkaline; still cloudy from phosphates. About seven a.m. the urine was much less alkaline, clear, and without any sediment. The daily variations in the reaction of the urine are recorded until the 28th of October. By means of the sulphite of soda, the vomiting was stopped, and the urine then became acid throughout the day. The second case was very similar to the first, excepting that no sulphite of soda was given. The patient remained in the hospital from the 6th of June to the 19th of August without any relief from the vomiting, and the alkalescence of the urine from fixed alkali was constantly observed. Hence, when an excessive quantity of acid fluid was thrown out of the stomach, an alkaline state of the urine was produced; and the alkalescence of the urine was lessened, or was made to disappear, when the vomiting was stopped.

That the occurrence of sarcinæ in the vomited matter has no direct relation to the alkalescence of the urine from fixed alkali, is shown—first, by the details of a case in which sarcinæ were vomited, but no alkalescence of the urine occurred; and secondly, by the details of another case, in which the vomiting depended on organic disease of the pylorus, and was far more urgent than in the previously mentioned cases; the vomited matter contained no sarcinæ, and the urine was almost always alkaline from fixed alkali. The author states that the following is the practical point of his paper. If the stomach does so directly influence the reaction of the urine as to cause it to be alkaline at one hour and over acid at another hour of the same day, then the prescription of acid or alkaline medicines must never be made to depend on the reaction of the urine passed at any one period of the day; for at one hour acids may appear to be indicated, and at another alkalies. The reaction of the total quantity of urine passed in twenty-four hours ought to determine the prescription of acids or alkalies when their chemical action on the urine is required; whilst the hourly variations in the reaction of the urine, when excessive, must be controlled by directing our remedies to the stomach, and not to the kidneys.

ON FATTY DEGENERATION OF THE VOLUNTARY MUSCLES.

By Edward Meryon, M.D.

The author commenced with the history of a youth, G. H. P——, who was born a fine and apparently healthy child, but at about the age of four years began to manifest some degree of weakness of the legs, which gradually increased, in spite of all remedial measures, until he was eleven, when he could neither walk nor stand; the muscular power of the arms then began to diminish; and eventually both legs and arms were perfectly powerless. When about seventeen, he was seized with simple fever, which terminated fatally; and his body was examined twenty-two hours after death. The viscera of the head, chest, and abdomen were perfectly healthy; the sinuses of the dura mater contained a very loose and thin coagulum, but the brain itself, and the spinal cord, as well as the communicating nerves and the nerves of organic life, were perfectly healthy. The relative proportion of grey matter to white, as compared with the nervous centres of another youth of the same age, and when examined under the microscope, the ganglionic cells of the grey substance, the tubular structure of the white, and the white matter within the neurilemma, wherever examined, whether in the cord itself or the out-branching nerves,—all bore evidence of a healthy condition. The chief structural lesion existed in the muscular system, which was throughout the whole body atrophied, soft, and almost bloodless; and although the muscular fibres *appeared* to exist, yet were they of an ochry colour, and very flabby. When examined under the microscope, the striped elementary primitive fibrils were found to be completely destroyed, the sarcous element being diffused, and in many places converted into oil-globules, whilst the sarcolemma was broken down and destroyed. Two younger brothers exhibited precisely the same symptoms and the same physical condition at the same age. A fourth boy exists, but he has not yet arrived at the age when the others began to fail. There are six girls in the same family, but none of them have exhibited the slightest tendency to the same form of disease.—The author then related the history of another family at Southampton, in which the two sons were similarly affected, whilst the two daughters entirely escaped. Another family in Sussex he also spoke of, in which there were three sons and one daughter, the sons being similarly affected, but at a later period of life, the daughter remaining in perfect health. In speaking of the cause of the disease, the author attributed it to original weakness and deficient action of the assimilating organs, and an absence of those elements and influences which are necessary for a healthy organization. Instead of the higher products of animal organization (albumen and fibrin), those only are produced which are shared in common with plants and minerals. If the cause of the disease were simply a defalcation of nervous energy, he supposes that the fatty deposit would be interstitial, as in paralysis; but it is not so: hence to the deficiency of those plastic elements for the necessary consumption of the peripheral system, he refers for the antecedent physical cause. The diagnostic signs of the disease, he thinks, may be,—1st. The negative one of absence of symptoms indicating active nervous disturbance, such as pains in the back or head, rigidity of the trunk, tremulous motions of the limbs, &c. 2nd. The very slow and almost imperceptible loss of power. 3rd. The perfect command of the bladder, which is not the case in paraplegia. His treatment has been guided by the conditions which Mr. Paget has enunciated as necessary to healthy nutrition,—viz., 1st. A right state and composition of the blood. 2nd. A regular and not far-distant supply of blood. 3rd. A certain influence of the nervous system. And 4th. A natural state of the part to be nourished. These conditions he has endeavoured to fulfil:—1st. By supplying to the blood those fibrinous elements in which it appears to be deficient. 2nd. By stimulating the capillary vessels in the interstices of the muscular fibres, by exercises of various kinds. 3rd. By communicating to the muscles artificial electric currents, which in the healthy state have been shown by Matteucci to be produced by the molecular changes which are con-

tinually occurring in the muscles themselves, the interrupted current by the toothed wheel of Masson being attended with more beneficial results than the continued current. By such means his surviving patients have thus far been improved.

Mr. Charles Hawkins remarked that it was curious that the disease in these cases should, as in some other instances, be confined to the male sex. At the time Sir B. Brodie had seen the case detailed by Dr. Meryon, he had mentioned to him (Mr. Hawkins) three or four cases occurring in boys. The brother of the mother had suffered from the disease, and she had transmitted it to her sons, and not to her daughters. There was also a peculiar deficiency of vision, which was transmitted by daughters to their sons, but not to their female children.

Mr. Arnott had listened with much interest to the cases detailed in the paper, because, anterior to the time when the spine-pulling and the tendon-cutting were resorted to, he had seen these children on several occasions. He would beg to inquire whether the spinal marrow had been examined: he did not mean cursorily; but had it been closely inspected, and its fibres microscopically examined? He asked this question, because his opinion was, that the muscular change was secondary; for when he first saw the child there was no want of development in the lower extremities. The child, he believed, was then about seven years of age, and was able to get up and down stairs; he was also able to get upon a poney, but, as the servant said, he got on "in a lump." He was asked if there was disease of the bones of the spine, but he had been unable to discover any. Looking, then, at the fact that there was no defect in the muscles of the lower extremities, that they were merely flabby, and not less than usual, or emaciated, he was inclined to the opinion that the original cause was not in the muscular system, but that it was dependent on a defect of nervous energy, probably dependent upon some hereditary cause—an opinion strengthened by the facts mentioned by Mr. Charles Hawkins. It was satisfactory to know that Dr. Meryon's treatment had been productive of benefit: he was evidently on the right scent. He (Mr. Arnott) had administered steel only.

Mr. Streeter trusted that when Dr. Meryon replied to Mr. Arnott's question, he would also state the condition of the ganglia of the posterior column of the spinal cord.

Dr. Meryon had not been aware that Mr. Arnott had been consulted, or he should have certainly mentioned the fact in his paper. He did examine the nerves, the medulla oblongata, and the spinal marrow, very closely, with the microscope, and in no one part was he able to trace the slightest departure from a healthy condition. He had expected to find some marks of disease in the nervous centres, and hence his examination had been most careful; but the nervous structure was in every respect healthy. The ganglia of the posterior columns were also healthy. He did not examine the structure of the bones; but he had examined the heart, the gastrocnemius, the soleus, the extensor abdominis, the biceps, the sterno-cleido, the omo-hyoid, and other muscles; and in all there was more or less signs of degeneration. With respect to the mental development, there was nothing at all particular. He regretted that he was not aware that his paper would have been read that evening, or he would have exhibited the results of his microscopical examinations.

Dr. Barker said, that having been alluded to in the paper, in consequence of one of the cases detailed having for some time been under his care, he would allude to one or two circumstances, in connexion with it, which were singular. The principal points of the case were, that the man had begun to be weak in certain muscles for two years before his admission into the hospital. The weakness gradually increased, having commenced in the muscles of the thigh and arm; and in these, when he came into the hospital, he was powerless. The muscles in the forearm and leg were, on the contrary, firm and powerful. The man was well made, naturally he was strong and vigorous, and there was no ascertainable cause for the degeneration of the muscular system. No light was thrown upon it by examination. There was no symptom, from first to last, excepting the loss of power in the limbs, of any disease of the nervous system. The thigh and arm were so completely wasted, that no remnant of the muscular system was left. No good resulted from the treatment adopted, and the man left the hospital in despair. No other part of the muscular system was affected, and it is singular that there was no waste whatever of the muscles of the forearm and leg.

Dr. Mayo remarked that the wasting of the muscles, as mentioned by the last speaker, was in relation to physiological laws. As age came on, the muscles which were affected in Dr. Barker's case were the first to lose their power—a fact which had been noticed by Shakespeare.

Dr. Meryon observed, that the man who had been in St. Thomas's Hospital, under the care of Dr. Barker, still remained in the same state. His brother is able to drive a cart by means of his legs; he is not so bad as the other, and attributes his better condition to the circumstance of his "having battled with the disease." With respect to the development of the limbs, in the case mentioned by Mr. Arnott, it was certainly true that they were remarkably well developed. No one, to look at them, would have supposed that they were not healthy; but when the arms or legs were bent, there was no feeling of muscular contraction; they felt soft and doughy. In these cases, the disease advanced from the extremities to the centre, in opposition to what Dr. Mayo had said was the physiological law of decay. With respect to some hereditary cause in these cases, he might observe, that his opinion on this point coincided with that of Mr. Arnott, and had influenced his diagnosis. It was true, as Mr. Hawkins had stated, that the brother of the mother of these children had lost muscular power, but he had been subject to fits, and was not examined: it was not the same disease.

Mr. Hawkins said Sir B. Brodie had regarded it as the same disease.

In answer to a question from Dr. Barlow, Dr. Meryon said that no experiments were made in respect to the irritability of the muscular fibre in these cases.

Mr. Hodgson considered that there were two conditions which might in these cases give rise to want of power in the muscles: first, some morbid state of the nerves or of the sources from which the nerves arise; or, secondly, some abnormal deposit in the sarcolemma or sheath of the muscular fibril, instead of that peculiar modification of albumen which constitutes fibrin or proper muscular structure. Perhaps this abnormal deposit might be fat, and the want of power in fatty degeneration of muscles might, in some instances, be owing to this condition, and in others to lesion of the nerves only. He considered this inquiry one of great importance, both with reference to pathology and treatment, and would like to ask some of the fellows of the Society who were much engaged in microscopic pathology, whether, when muscles had degenerated from inaction, or affections of the nerves, as in ordinary cases of paralysis, or from the effects of lead, it was found that fat was deposited in the sarcolemma of the muscles, instead of the proper material, or whether there was merely a deficiency of the latter and the fat was deposited in the interstitial filamentous structures?

Dr. Meryon had not himself been able to get a paralyzed limb to examine; but Mr. Quekett had examined several, and his authority on the subject had been quoted. In these cases the deposit of fat was always interstitial. In answer to questions, Dr. Meryon said that there was nothing peculiar in the size or shape of the brain; nor was there anything peculiar in the musculus detrusor urinæ.

Mr. Adams said that in paralysis from disease of the nervous centres, the fibres of the detrusor urinæ were wasted. He should therefore look for the primary cause of the affection, in Dr. M.'s cases, to the organic system of nerves.

Dr. Theophilus Thompson remarked, that all the replies and remarks which had been made, tended to take us to a cause beyond the reach of the microscope or scalpel, and depending on some deficiency in the vitality or vigour of the original constitution.

ADDRESS

DELIVERED AT THE FIRST MEETING OF THE

DUBLIN STUDENTS' MEDICO-CHIRURGICAL SOCIETY.

By Mr. Henry James Wilson,
House-Surgeon to the City of Dublin Hospital.

Gentlemen,—The occasion upon which I have the honour to address you is one fraught with importance and interest to the Medical Students of Dublin, and my only regret is that so arduous, but still pleasing a duty, has not been entrusted to abler and better hands. The city of Dublin has always been celebrated, and justly so, for its medical schools; from her colleges have gone forth men an honour to themselves, their profession, and their country; men remarkable as well for stability of judgment and rapidity of decision, as immoveable firmness and presence of mind. These are the great qualifications which befit a man for the medical profession; upon these alone must he hope to rise to eminence, and be held in respect by all good and educated men. It is while we are students that these indispensable necessaries must be attained; it is while attending our hospitals and schools that this commanding eye of an enlightened understanding must be formed; it is then we must learn to recognize that which is hidden in darkness; to distinguish certainty from uncertainty; to separate essential from accidental. You must note carefully what comes before you; you must analyze the precepts of your teachers; you must not allow yourselves to be carried away by brilliant and fanciful theories, no matter by what illustrious individual they may be promulgated, unless indeed they be established by clear and conclusive experiment. To this cause alone can be assigned the slow progress of medicine and surgery through so many centuries; while, on the other hand, the sister science chemistry, during the same period, has made such rapid strides towards perfection; and permit me to ask you why is it so? Because medical men, instead of working out those fundamental truths which are the basis of the science, and being thence led on, step by step, up the rugged hill of knowledge, until they should have gained the summit, have rushed headlong after the phantoms of their own imaginations, seeking to establish their own theories by consigning to oblivion those founded on time and observation.

Gentlemen, I am sorry to say that this evil spirit continues even to our own day; men seem to have profited nothing from the sad experience of the past, nor will they, even now, pay attention to the warnings and entreaties of their brethren. Not such, indeed, has been the conduct of the sons of chemistry; they have laboured hard, and still labour in the right path; they establish nothing upon mere hypothesis; they cast aside and discard all speculations not based on experimental truth. It is, then, by making ourselves thoroughly acquainted with the received opinions of the day; and noting carefully the cases which come under our observation in hospital, that we may hope to acquire that knowledge and acuteness so essential to the successful practice of the science of medicine.

For the furtherance of this great object, the Dublin Students' Medico-Chirurgical Society has been formed, the purpose and ends of which Society the provisional committee, in placing me in this chair, have deputed to lay before you, in order that those gentlemen, who have already become members, may clearly understand the design of its formation; and those who have not, may be induced to add their names to the fast increasing list of its supporters. The objects of the association shall be to afford the Medical Students of Dublin an opportunity of improving themselves in *medicine, surgery, the collateral sciences, and the art of composition*. This improvement will be gradually but not the less certainly developed by the members writing papers upon any subject connected with their profession, which may either suit their taste or information, and by reading the same before the public meetings of the Society, where free discussion (subject to the opinion of the chair) is permitted. That advantage will be derived from the efficient management of the Society, no reasonable doubt can be entertained. By admitting as members the students of all the various hospitals and schools, every interesting occurrence and remarkable event that may happen in such an extensive field of medical and surgical practice will be made known to us. It will be, as it were, concentrating every hospital into one. It will establish closer and firmer bonds of friendship between us, such as should always exist amongst members of the same profession. It will excite within us a desire to watch more closely the various phenomena of disease, to become acquainted with the symptoms in their rise and progress, and the remedies employed for their alleviation.

I mentioned improvement in the art of composition as being one of the objects of the Society. Gentlemen, if this were the sole cause or excuse for its formation, it would be one more than amply sufficient to the world. There is nothing so essential to the renown of a medical man as a profound knowledge of this art; without it, he is unable to communicate his ideas properly to mankind. If this be true, why is it we see it so frequently wanting? Because, gentlemen, it is not sufficiently practised; for it is by practice, and by practice alone, that any proficiency in the art can be gained. Is it reasonable to expect that any man, no matter how great may be his native genius, on first sitting down to communicate his thoughts to paper, can do so in a style sufficiently clear and lucid as to convey to his fellow-man any knowledge of what he means? On looking into ancient history, we see what a stress the Greeks and Romans laid upon the acquirement of this accomplishment; they even established schools in which their young men might learn the art of declaiming and writing. What has been the consequence? Why, that the most noble and beautiful sentiments which ever flowed from the lips or pen of man rewarded them for their foresight; sentiments as much sought after and praised by the *literati* of our own day, as the lovers of beauty and art in their own age.

Again, the writing reports of any remarkable cases which may come under your observation, occupies a prominent position in the intentions of the Society, and most properly so. It is an established fact, and one well worthy of observation, that the man who notes carefully the cases which come before him performs a more valuable achievement for the benefit of medical science, than he who invents a dazzling theory. The truth of this maxim has been seen and observed by men following other professions as well as our own. That illustrious philosopher, Lord Bacon, passes a high encomium on its utility, and refers his readers to the pages of that father of physic, Hippocrates, and points out how medical science has been benefited by that eminent sage's beautiful collection and arrangement of facts.

So much, gentlemen, for the advantages to be derived from the Society; permit me now, for a few moments, to turn to the consideration of its prospects. Whether this shall become a prosperous and flourishing association, or whether, after having enjoyed a brief span of existence, it shall fall away and be entirely forgot, depends upon yourselves. On your exertions now hangs its life. You are the mainspring of its action; the vital principle of its being. The least hesitation or indecision on the part of any one of us will tend to paralyze its action. Join, therefore, hand in hand, one with another; cast aside all trivial jealousies; labour earnestly and properly for its benefit, and in a few months we shall have the pleasure to behold it gain strength with its age, and serviceable to all. Let it not be said, gentlemen, that the Medical Students of Dublin were not able to form a society; or, having formed one, not able properly to conduct it. Show to the world that the men of the rising school will not be one whit inferior to those that have gone before them; and that medical science by being entrusted to their hands shall suffer no deterioration. As yet there is no cause of complaint; the Society has been but a very short time in existence, and already thirty-seven gentlemen have enrolled themselves as members, and I hope this may be, as it were, but

a speck on the horizon to those that will follow. Go on as you have commenced, and prosper. Before long we shall see it cast off the shacklesome garb of infancy; and in putting on that of manhood, assume all its strength. And when we no longer fill the rank of students, we may, with feelings of pleasure and pride, behold that Society which was commenced under our auspices, both flourishing and useful.

I feel that I cannot more appropriately conclude these few brief and, I fear, imperfect observations, than by returning thanks, on the part of the Society, to those honoured gentlemen of the medical profession who have this evening favoured us with their presence. It shows, at least, that they have the welfare and advancement of the student at heart, and that they are determined to benefit him by every means in their power.

Arthur H. Taylor, Hon. Sec.

REVIEWS AND NOTICES OF BOOKS.

THE DESCRIPTIVE AND SURGICAL ANATOMY OF THE ARTERIES AND RELATIVE ANATOMY OF THE VEINS AND NERVES OF THE HUMAN BODY. By J. H. Corbett, M.D., Graduate of the University of Edinburgh, Licentiate of the Royal College of Surgeons in Ireland, Professor of Anatomy and Physiology to the Apothecaries' Hall, &c. &c. Dublin. 1851. pp. 355.

The vascular system would appear to have greater attractions for the student of anatomy, and to be likewise a more favourite subject with the anatomical teacher, than either the muscular, nervous, or osseous systems. In this city, at least, it has received the largest share of attention; commensurate, however, only with the importance of the subject, whether considered in its relations to physiology or in its bearings upon operative surgery.

The object of the work before us is to present the student with a clear and concise, but sufficiently full, description of the anatomy of the vascular system, adapted either for the dissecting-room or for the study. "In its preparation, the author's principal aim has been (the preface states) to fix the reader's attention to the immediate object of his study; to avoid all matters calculated to divert the current of his thoughts; to describe the relations of each artery in a systematic form; to dwell chiefly upon the points most important to be learned by the student, whether engaged in ordinary dissection or in preparing for his final examination. It is also intended that the reader, when tracing the arteries, should experience assistance in acquiring some knowledge of the accompanying veins and nerves without additional labour or loss of time."

A work upon descriptive anatomy, published at the present day, could not be expected to contain much novel matter; nevertheless we find in more than one place in Dr. Corbett's treatise remarks upon points in the arrangement of tissues which have been either overlooked by other anatomists or have been insufficiently considered. The description of the relations of the brachial artery is an example; we shall therefore quote a portion of it here, as it will, at the same time, enable our readers to judge of the author's style and descriptive powers:—

"In the first step to be taken with a view to expose the artery, an incision should be carried through the integument, from the inferior margins of the pectoralis major and latissimus dorsi to the middle point between the condyles of the humerus; the dissector taking the coraco-brachialis and internal side of the biceps flexor cubiti as his guide. The skin ought to be raised separately in order to study the course of the superficial veins and cutaneous nerves. . . .

After the removal of the areolar membrane and adipose tissue, the fibrous fascia of the arm is laid bare.

This fascia, or brachial aponeurosis, conceals the vessels, and affords a general investment to the muscles of this region. At the superior extremity of the limb it is attached to the clavicle, acromion process, the spine, and posterior border of the scapula. From these points it descends over the muscles of the shoulder and arm to its inferior extremity, where it is adherent to the eminences of bone around the elbow-joint, and thence continued over the muscles of the forearm. At the thoracic side above, it is continuous with the fascia, which is folded beneath the base of the axilla, and it receives fibrous accessions from the tendinous insertions of the great pectoral, deltoid, latissimus dorsi, coraco-brachialis, and semilunar fascia of the biceps; it sends off two strong fibrous processes, named, from their position, internal and external intermuscular septa, which become intimately connected with the prominent ridges that lead on each side of the shaft of the humerus to the two condyles.

The brachial aponeurosis should next be divided in the line of the cutaneous incision, or longitudinally over the surface of the biceps. The latter method should be preferred by the inexperienced anatomist. It is then to be dissected carefully to either side of the arm, so as to bring in view the biceps, coraco-brachialis, and brachialis anticus, as far as the internal and external intermuscular septa; but it will become necessary to remove the fascia from the triceps muscle when proceeding to trace the principal branches of the artery.

After the elevation of the fascia from the anterior and internal part of the arm, the outline of the artery and its accompanying parts can be noticed, although not fully displayed. The student is particularly recommended not to make any additional dissection at this stage, but to examine its course as it lies undisturbed amidst its relations.

The brachial artery, its venæ comites, and the median nerve, are comparatively superficial, being covered by the integument, the areolar, and adipose tissues, and by that portion of the brachial aponeurosis which extends from the inside of the arm to the anterior surface of the biceps flexor cubiti. The artery is also protected by an areolar investment, sometimes termed its sheath, and near the elbow-joint by the semilunar expansion of the biceps tendon. It is not, therefore, necessary to divide any muscular fibres in the dissection of the brachial trunk; but it should be well remarked, that it is overlapped by the coraco-brachialis at its superior part, and by the internal margin of the biceps in the middle and inferior portions.

It may be now observed, that the superior part of the artery (the brachial fascia having been removed) has only a delicate fibro-cellular covering; but on drawing outward the belly of the biceps, that portion of the artery below the middle of the arm is retained in contact with the surface of the brachialis anticus by a distinct fibrous expansion, which should not be confounded by the dissector with the semilunar fascia of the biceps, nor with the brachial aponeurosis just examined.

The fibrous covering, which still confines and secures the artery, is a distinct structure entitled to consideration, although disregarded in anatomical descriptions. It cannot be seen satisfactorily unless carefully dissected, and in the usual method must often be removed with the brachial fascia, or mistaken for an ordinary kind of sheath. Its strength varies according to the degree of muscular and fibrous development, and it is better marked for two or three inches opposite to the inferior fleshy part of the biceps than above or below that region.

It appears analogous in many respects to the aponeurotic structure which extends across the femoral artery in the middle third of the thigh. Its fibres may be described as passing from the internal head of the triceps and internal intermuscular septum, somewhat diagonally across the artery, venæ comites, and median nerve, so as to confine them in their situation upon the brachialis anticus, and to protect the vessels from pressure during muscular action.

Let the student bend the forearm upon the arm, and he will find the artery to be thrown into a curved condition beneath this protective membrane, or, as it may be termed, deep brachial aponeurosis."

The operations upon the arteries are described in a separate chapter at the end of the volume, to which the student may refer when he has made himself master of the relative anatomy of the vessels upon which it may be necessary to apply a ligature. And, in addition to the anatomy of the arteries, the author has added a sufficiently full account of the anatomy and relations of the veins throughout the body.

Upon the whole, Dr. Corbett's treatise appears to us to be admirably adapted to the purpose for which it is intended, and we have little doubt that it will soon become a favourite with the student.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 31, 1851.

COMMENTS ON THE DISPENSARY ACT.

It is unnecessary for the purpose of testing the powers of the Dispensary Act to continue the enumeration of the proceeding of unions in detail; the more especially because the information extant on the subject is necessarily imperfect. Presently official returns will reveal the results, and afford a basis upon which a systematic plan can be arranged. In the meantime sufficient has been ascertained to enable us to distinguish the important features of the measure, and to perceive the defects incident to its operation. Two principal objects now engross attention: the division of the unions into dispensary districts, and the fixing of the remuneration to be provided for medical services. The division into districts, rendered more difficult by the compulsory adjustment of them to the electoral divisions, is obviously a labour of no very easy achievement. Had the medical relief been provided for by an assessment on the union at large, a better division into districts might, perhaps, have been effected; but this, we conclude, was not attainable in conformity with the principle which distributes the taxation. As the case stands, the Guardians in many places have been compelled to form divisions of excessive dimensions, and in other places have voluntarily done so to evade the law, and thereby save the expense of additional districts. We hear of districts in some places thirty miles in length; for the care of which the Surgeon has had £60 a year allotted him. This is, of course, a mere evasion of the act; for no man could discharge the duty which such an arrangement contemplates, and to correct such evasion the Commissioners must interfere. The amount of salaries to be paid for a Surgeon's services necessarily leads to difference of opinion; and the all-powerful motive of economy cannot fail to bias the Guardians in their estimate of the amount honestly due. In some unions a fair sum has been granted, but in the majority it is so utterly inadequate that the Commissioners must interpose. Indeed, it is clear that so powerful is this motive which prefers economy before every other consideration, that nothing but the compulsory action of the poor-law, as applied in other cases, will counteract it. The Guardians must be taught that this act, passed after mature deliberation, to provide effectual medical relief for the poor, must be carried into effect, however unpalatable the consequences may be, and that their acquiescence regarding it is not merely optional. Now is the time to inculcate this disagreeable truth, and once for all to undeceive those who think that laws are to be obeyed just according to the opinions which may be entertained respecting their necessity. The ratepayer must pay his two, three, or more pence in the pound for the medical care of the labourer, and whatever he may think to the contrary, ten, fifteen, or even twenty shillings in his rate, is no very exorbitant demand for such an object. Some would fain persuade themselves that a salary of £100 a year is much too large for a Dispensary Surgeon, not because he does not earn it, but because the union cannot afford it; yet we cannot bring ourselves to believe that a union of five districts should not allocate £500 a year to such a purpose. The Commissioners may not find it easy to lay down a rule as to the minimum or maximum salary applicable to all cases; but the more we look at the matter, the more do we lean to the conclusion that salaries of £100 a year are not excessive in a financial point of view; while in justice to the poor and their medical attendants, they are scarcely adequate. This appears so obvious, that we would strongly recommend our brethren to argue the matter on such grounds, and not to make the question turn upon the feeling which may be entertained toward them personally. The less reliance placed on partiality or favour the better. The Dispensary Surgeons are entitled to proper payment for their services or they are not; and if this payment be denied, a remedy for such injustice must be found. The exploded system of medical relief by voluntary subscription and grand jury presentment has so accustomed the country gentlemen to habits of dictation in this matter that they will not for some time quietly acquiesce in the new arrangement which curtails their patronage and authority; the Dispensary Surgeons must therefore act with prudence and forbearance, satisfied that they have been emancipated from a control which grievously crippled their exertions in private practice. Such considerations suggest the question next in importance, the question of the restriction of gratuitous medical relief to proper objects; and here again the habits established by the former system come into conflict with the new law. Already the claims of indigent persons to gratuitous medical relief are earnestly put forward, and great danger exists of a perpetuation of the old system under which every one, however comfortable in circumstances, received it, if mean enough to seek it. That the labouring poor and their families will be entitled to such aid there can be no question; but that employers, shopkeepers, and tradesmen earning good wages, will be so, remains to be proved. Small proprietors receiving incomes from small farmers will naturally enough wish to relieve their needy tenants from this or any other expense which may diminish their means of paying the rent; and will doubtless "take the worth of their money out of the doctor" if permitted; but such mischievous temporizing will scarcely be tolerated. It is admitted on all hands that one of the numerous causes of this country's unfortunate condition is the propensity of the people to seek assistance from extraneous sources instead of relying upon their own exertions, and here is an example of it. Every Surgeon in Ireland can bear testimony to the fact, that the applicants for gratuitous relief, both in public and private practice, are in numberless cases persons well able to pay for such assistance. Not of course to pay guinea fees, but such sums as their circumstances permit, and such sums as in the gross will enable many practitioners to live in situations where they must otherwise starve. The act appears to us quite adequate to correct this abuse. The 9th clause provides that "Any poor person" may obtain a dispensary ticket, entitling him to relief, but if found "not to be a fit object for dispensary relief," the ticket may be cancelled by the committee. That the committee men, relieving officers, and wardens, authorized to grant these tickets, will grant them to persons, not being "poor persons" within the meaning of the act, and being "unfit objects for dispensary relief, is certain;" and that the Dispensary Committees will not cancel such tickets in many cases is equally certain, but the check which this arrangement creates will, to a certain extent, operate effectually; the more especially, because the same clause directs that the form of the ticket shall

be prescribed by the Commissioners, who will doubtless cause it to run to the effect, that the bearer is "a poor person," and "a fit object for dispensary relief." Temptations to grant these tickets should be carefully counteracted. Relieving officers and wardens must be watched to prevent the issue of them for "a consideration;" a pullet, a pound of butter, or a dozen of eggs, will prove very effectual to this end; petty shopkeepers placed on the committees must also be looked after, or they will turn the tickets to account to "draw" customers. To notice such matters as this may appear very undignified and humiliating, but we have now to handle the realities of the proposed plan, and to suggest safeguards for its practical application. We shall presently have much conflicting testimony and argument as to the meaning to be attached to the words "poor persons," as applied to persons seeking gratuitous medical relief, and guardians, ratepayers, and committee men will probably lean to a very loose interpretation of them; seeing that "the doctor" once paid, the expense cannot be much increased by additional claimants; but this must be met by a few homely lessons in political economy, and a cogent hint as to the lurking of the principle of socialism under this apparently simple matter of detail. One point the Commissioners must touch notwithstanding its tenderness; and that is the question whether domestic servants are to be held "poor persons" and "fit objects for dispensary relief" within the meaning of the act. That such when unemployed should be so considered may be admitted, but that when in comfortable situations it becomes a different question. However decided as to the administration of relief at the dispensary, it is clear that the District Surgeon should not be compelled to visit servants in their masters' houses; such a tax on his services being likely to lead to results humiliating to his professional character. In process of time the family medical attendant will practically afford a remedy for any difficulty which may arise, but the Dispensary Surgeon must no longer be ordered here and there as the squire thinks fit. We hear of an amusing solution of this difficulty, some board of guardians, we know not which, finding that £30 ratepayers being eligible as committee men, consider that all below that rating should be held eligible for gratuitous relief. This is characteristic. Our limits, however, do not permit us to dwell longer on this subject at present. We must return to it presently.

ALTERATION OF SURGICAL RIGHTS IN ENGLAND.

The draft of the New Charter of the College of Surgeons is in the hands of the college printer, and it is to be made public to the profession in a few days. It will be remembered that Sir George Grey promised that the profession should have an opportunity of learning the provisions of any charter agreed upon by the council of the college before it was finally granted by the Crown. The draft of the proposed charter will be disseminated in accordance with this ministerial pledge. It will then be for the profession to pronounce upon its provisions; and there can be no doubt the minister will listen to the professional voice, whether it be one of approval or disapproval. The only change of consequence from the provisions of which the profession are already aware, is one respecting the mode of voting at elections for the council by fellows residing in the provinces. At one time the council had agreed to allow fellows residing at a certain distance from London, the privilege of voting by proxy. This has since been altered, and according to the provisions of the charter which is soon to see the light, all fellows will be obliged to attend in person in London to record their votes. The probability of an approaching settlement of the questions which in recent years have agitated the College of Surgeons, is one which every true lover of the profession will hail with pleasure. The next question for professional solution is—What can be done with the College of Physicians?—*Lancet.*

We have since received this draft, and from it we gather that one object of it is to enable the General Practitioner to become candidate for the Fellowship; but as the title of General Practitioner is not made use of, we cannot well understand the nature of the proposed change. It seems to contemplate the exclusion of all persons keeping apothecaries' shops, but to permit the admission of Surgeons supplying medicines to their own patients. There are other salutary changes provided to meet the wants of the present generation, and to give to the profession of surgery that independence which its importance demands. We rejoice to see the English and Irish Colleges of Surgeons adopting active measures to uphold the rights of their members irrespective of the attempts of other bodies to encroach on them.

MEDICAL EVIDENCE IN CASES OF INSANITY.

(From the Journal of Psychological Medicine.)

The November number of *Blackwood's Magazine* contains an elaborate analysis of the first volume of a work entitled Modern State Trials. The analysis in question is said, upon good authority, to be written by Mr. Samuel Warren, the well-known author of the Diary of a Late Physician, and Ten Thousand a Year. Of this gentleman's high literary attainments we wish to speak with great respect, but we cannot allow him or any other member of the legal profession, however distinguished may be his position, or varied his attainments, unjustly to attack that section of the medical profession especially called upon to give evidence in our courts of justice in cases of insanity, without entering our formal protest against it. Unfortunately there appears to be but little sympathy and kindly feeling between the members of the *bar* and the professors of *physic*. The aggression is certainly not on our side. We have not been the assailants; the psychologist is solemnly called upon to elucidate in our courts of law points of great intricacy, requiring on his part not only a mind well stored with facts, the result of much experience and observation in the treatment of the insane, but of an understanding fitted by natural organization and training for the ready appreciation of the highest order of mataphysical truth and evidence—viz., that connected with the deviations of the mind from a state of health and responsibility. He is supposed—and rightly and justly supposed—by education, study, reflection, and enlarged experience, to be capable of enlightening the court and the jury upon matters with which they are necessarily but superficially acquainted, and he is subpœnaed to give the benefit of his scientific knowledge in cases involving often the questions of life and death. Surely it is the duty of the legal profession if they differ from the views generally propounded by medical men in relation to the plea of insanity to respect their opinions, however opposed they may be to those which they themselves entertain. Sad will be the consequences if, as the results of the injudicious and uncalled for language of the bench, and the raillery and misplaced wit of the bar, the public should be taught to undervalue or think lightly of the evidence of the medical psychologist in cases involving the subject of crime and insanity, responsibility and irresponsibility. That such, alas! is the unhappy *tendency* of events we infer from the remarks which are said to have fallen from the lips of the Lord High Chancellor of England, as referred to in an able contemporary. We quote the following passage:—

"During the recent hearing of a lunacy case, the Lord Chancellor is reported to have said, 'His experience taught him there were very few cases of insanity in which any good came from the examination of medical men. Their evidence sometimes adorned a case, and gave rise to very agreeable and interesting scientific discussions; but, after all, it had little or no weight with a jury.' Whatever may be the respect we entertain for this high authority, we emphatically dissent from these views, believing them to be founded in error, and totally unjust to practitioners in medicine, who are not only the most important but often the only competent witnesses,

in inquiries respecting insanity. That medical evidence does not always produce the impression it ought upon the individuals addressed, we readily understand. The judicial tribunal just mentioned, from its miscellaneous composition, must be occasionally unable to form correct conclusions respecting the very intricate points at issue; more especially as even great legal authorities themselves are sometimes far from being unanimous in opinion. Suppose an eminent medical professor were to assert, 'ex cathedrâ,' that 'the bar of England knew nothing of law, and that very little benefit ever accrued from their speeches. They might adorn a case, make an eloquent oration, or quote precedents, but all their arguments would never influence any twelve men sitting in a box.' Westminster Hall would be in an uproar against any member of the medical fraternity who presumed to utter such sentiments; and we acknowledge the lawyers might, in that instance, justly express their indignation. Each profession should respect the other, in its peculiar sphere, as all, the public included, will then gain by liberal and kindly bearing. As an illustration of the feelings which ought to prevail, allusion might be made to the late Lord Chief Justice, the son of a physician, and an able as well as dignified jurisconsult, when presiding at the trial of Oxford for treason. On that occasion the present Lord Chancellor, then a learned sergeant, having endeavoured to brow-beat a medical gentleman whilst giving evidence, was properly checked by the presiding judge, in order that the witness need not fear any forensic fervour of counsel. We therefore say to our brethren, when called upon to appear in a court of justice—state facts and opinions clearly, firmly, respectfully, and fearlessly."

The good sense and proper feeling of the concluding remarks of the above quotation, must be manifest to all. But to the case immediately before us. Mr. Warren, after giving a succinct account of the details of McNaughten's trial, observes as follows :—

"After going through the evidence (if the word can be used with propriety under such circumstances) of the other medical gentlemen, Mr. Townsend observes, 'Each physician and surgeon, as he stepped into the witness-box, seemed anxious to surpass his predecessor in the tone of decision and certainty; each tried to draw the bow of —— (mentioning the first physician who had been called, and who was also called in Oxford's and Pate's case, in which latter he was rebuked by Baron Alderson), and shoot, if possible, still farther into empty space. And this gentleman, Dr. ——, had asserted, under cross-examination by Sir William Follett, 'his positive conviction that he could ascertain the nicest shade of insanity! that the shadowy trace of eccentricity, dissolving into madness, could be palpably distinguished!' The last of these confident personages then was permitted to make this extraordinary statement: 'I have not the slightest hesitation in saying that the prisoner is insane, and that he committed the offence in question whilst afflicted with a delusion under which he appears to have been labouring for a considerable length of time!!!'"

We wish to speak respectfully of the dead, otherwise we might be disposed somewhat to cavil at the expression, "confident personage," used by Mr. Townsend, particularly as it is applied to the editor of this journal. We feel no uneasiness of mind, or compunctions of conscience, in thus "owning the soft impeachment," and admitting that Dr. Winslow is the "confident personage" spoken of in the passage quoted, and that the "extraordinary statement" was made by ourselves. We extract the paragraph containing the offensive epithet, with all its typographical embellishments. But whilst we thus leniently pass over Mr. Townsend's unjustifiable appellation, we are not so disposed to treat Mr. Samuel Warren's "adoption" of the phrase, or his comments upon it. The author of Ten Thousand a Year, after quoting Mr. Townsend, exclaims, in an affected spirit of honest indignation, "We feel constrained to say that this appears to us, in every way, monstrous." "Monstrous!"—why monstrous, Mr. Warren? The witness was upon his oath. His mind could not, with any degree of reason, have been supposed to be unduly biassed. He was not a paid witness. He had no connexion either with the prosecuting or the defending party. But being in the court at the time of the trial, he was requested by Sir A. Cockburn to enter into the witness-box, to give his opinion on a point of science; having heard all the evidence, *pro* and *con*, Dr. Winslow was asked, as a person supposed to have some practical knowledge of insanity, to give the jury his opinion of McNaughten's probable condition of mind when the act, for which he was being tried, was committed? Dr. Winslow in reply to the question gave the evidence, which Mr. S. Warren, with unpardonable effrontery, stigmatises as "monstrous" What was the "result" of that evidence? Let Mr. Townsend answer.—

"Chief Justice Tindal here interposed, to ask Sir Wm. Follett whether he was prepared with evidence on the part of the crown to combat that of the medical witnesses—

"'Because, if you have not,' said the Chief Justice, 'we think we are under the necessity of stopping the case. Is there any medical evidence on the other side?'

"Sir William Follett—'No, my lord.'

"Chief Justice Tindal—'We feel the evidence, especially that of the last two medical gentlemen who have been examined, and who are strangers to both sides, and only observers of the case, to be very strong and sufficient to induce my learned brothers and myself to stop the case.'"

The evidence of Dr. Winslow did not alarm the discreet, the able, the penetrating, and sagacious mind of the Lord Chief Justice. It was not "monstrous" in his estimation. That distinguished jurist—perhaps the most illustrious judge of modern times—saw in the twinkling of an eye, what Mr. S. Warren, with all his wonderful penetration, cannot after the lapse of years, with the evidence of the trial in detail before him, conjoined with a knowledge of the facts connected with the history of McNaughten since his confinement in Bethlem for a period of "eight" years perceive. Lord Chief Justice Tindal saw that the insanity of the prisoner was placed beyond the slightest shadow of a doubt—and such also was the conviction of Dr. Winslow when he gave the "monstrous" evidence alluded to by Mr. Warren. There could be no question as to the fact of McNaughten's mental derangement. Cases of insanity are sometimes made the subject of investigation in our criminal courts, in which the medical and general evidence is nicely balanced, and when the physician is justified in giving his opinion with extreme caution; but with regard to McNaughten, the delusions were so evident—so satisfactorily and conclusively established in course of the trial—that a conviction of his total wreck of intellect forced itself upon mind's most unwilling to receive it; not only was it proved that McNaughten was deranged, but that the criminal act sprang directly out of, and was almost the natural and inevitable result or sequence of, the morbid creations of his fancy; thus bringing the question of his responsibility fairly within the test laid down by the celebrated Lord Erskine, in the memorable trial of Hatfield—viz., that insanity should not exempt from punishment when the crime is not "directly traceable to a delusive impression."

McNaughten imagined that he was beset by conspirators, and with the view of protecting himself from these imaginary assailants, he carried about his person a loaded pistol—and influenced by this morbid idea, which embittered his very existence, he shot Mr. Drummond. It is a matter altogether distinct from the question at issue, whether he mistook Mr. Drummond for the late Sir Robert Peel. If that distinguished statesman had fallen in lieu of his secretary, it would not, in the slightest degree, have altered our view of the mental aspect of the case. Deeply as we should, in common with the whole world, have deplored the untimely and unhappy death of so great—so illustrious a man—a stern regard for "truth, justice, and humanity" would have compelled us to throw the shield of protection around the poor lunatic, deprived by inscrutable Providence of the right exercise of those faculties given to him for his guidance and self-control. Continuing his observations on the case, Mr. Townsend remarks :—"Nine medical witnesses had now spoken, with a wonderful unanimity of opinion, and the court surrendered at discretion.'"

"Surrendered at discretion!" Truth was established; the solemn and sacred claims of justice were vindicated. The able judge then considered it to be his duty to stop the inquiry, so convinced was "he" of the utter uselessness and folly of prolonging so painful an investigation. Did the intelligent jury hesitate? Did they retire from the box apparently unsettled in their minds as to the verdict they ought to return? No sooner had the Lord Chief Justice interfered, than the jury at once bowed to the just decision of Lord Tindal, and without the appearance of the remotest difference of opinion, returned an unanimous verdict of acquittal, on the ground of insanity!

And what says Mr. S. Warren of the effect on the court of the evidence of the "nine medical witnesses?" Hear him?—"If such a course is to be allowed again in a court of justice, what security have any of us for life, liberty, or property?"

Reverse the picture, and what would have been the sad consequences? Would Mr. S. Warren have "executed" McNaughten? What a spectacle of horror would such a cruel, disgraceful, and barbarous act have been in a Christian country like that in which we are privileged to live! As well might he go to the Highgate Institution for Idiots, and drag out from that abode of lost and ruined minds a poor drivelling, helpless, imbecile child, and inflict upon him corporeal chastisement for a non-comprehension of an honest distinction between *meum* and *tuum*. We do not believe that McNaughten knew or had the remotest conception that he was "acting contrary to the law of the land;" and if we were convinced that such an idea had passed through his mind immediately before he fired the fatal shot, it would not have altered our opinion of his insanity and total irresponsibility. We do not, as medical psychologists, recognize this as a scientific test of criminal responsibility. The mere consciousness of an act to which an insane person may be prompted, being "contrary to law," is not "to our minds" a sufficient proof of legal or moral responsibility. Mr. S. Warren thinks differently. So let it be: he is welcome to his opinion.

But what has been the history of McNaughten since his acquittal and confinement in Bethlem? Mr. S. Warren paid a visit to the hospital for the purpose of ascertaining his present condition. If his visit had taken place subsequently to his having written the whole of the review of Mr. Townsend's work, we should have looked forward to an article in a future number of *Blackwood*, recanting the opinions expressed in the communication before us. Our readers will participate in our surprise when they are informed that the formal examination of McNaughten (the details of which we shall presently give) was made prior to the completion of the article in question. This certainly appears to us to be most extraordinary. If Mr. S. Warren had found McNaughten a sane man, and had been informed that he had given no evidence of derangement of mind from the moment he was transferred from Newgate to Bethlem Hospital, then our opinion of his view of the trial would have been somewhat modified, and we should not have considered it our duty to make his paper the subject of a special article in our journal. We quote, without any further remarks of our own, Mr. Warren's graphic and interesting account of his visit to McNaughten:—

"McNaughten was standing in the courtyard, dressed in the costume of the place (a pepper-and-salt jacket and corduroy trousers), with his hat on, knitting. He looks about 40 years old, and in perfect health. His features are regular, and their expression is mild and prepossessing. His manner is tranquil. Usually he wears his hat somewhat slouched over his eyes, and slides slowly away from any one approaching him, as if anxious to escape observation; but on this occasion he at once entered into conversation with our companion, calmly and cheerfully, and afforded us a full opportunity of watching him. Had we seen him casually elsewhere, and as a stranger, we should have thought his countenance indicative of a certain sort of cheerful quiet humour, especially while he was speaking; but to us it seemed certainly to exhibit a feeble intellect, shown chiefly by a faint flickering smile, even when he was speaking on the gravest subjects. When asked what had brought him where he was, he replied, 'Fate.' 'And what is fate?' 'The will of God; or, perhaps (he added quickly), of the devil—or it may be of both.' And he half closed his eyes and smiled. [The reader will bear in mind what was deposed at the trial as to his infidel tendencies.] When told that Sir Robert Peel was dead, he betrayed no emotion, nor exhibited the slightest interest. 'One should have thought that, considering what has happened, you would have felt some interest in that gentleman.' He looked rather quickly at the speaker, and said, calmly, with a faint smile, 'It is quite useless to talk to me on that subject; you know quite well I have long and long ago made up my mind never to say one word about it. I never have, and I never will; and so it would be quite childish to put any questions.' . . . . . 'How are you, McNaughten?' He slightly sighed, and said 'I am very uncomfortable; I am very ill-used here; there is somebody, or something, always using me ill here. It is really too bad. I have spoken about it many, many times; but it is quite useless. I wish I could get away from this place. If I could just get out of this place, and go back to Glasgow, my native place, it is all I would ask for; I should be quite well there. I shall never be well or happy here, for there is always some one ill-using me here.' 'Well, but what do they do to you?' 'Oh! (shaking his head and smiling,) they are always doing it; really it is too bad.' 'Who are they?' 'Oh! I am always being ill-used here. My only wish now is, to get away from this place. If I could only once get to Glasgow, my native place!' This is the continual burden of his song. It is needless to say that his complaints are altogether unfounded; he is treated with the utmost kindness, consistent with his situation; and, as he has never exhibited violence nor ill-behaviour, it has never been necessary to resort to personal coercion, with one exception. Two or three years ago, he took it into his head that, as he could not get away, he would starve himself; and he persevered for such a length of time in refusing food, that he began to lose flesh fast. At length he was told by the physician that, since he would not eat voluntarily, he must be made to eat; and it was actually necessary to feed him for a considerable time mechanically, by means of the stomach-pump. Under this treatment he presently regained his flesh, in spite, as it were, of himself; and at length suffered himself to be laughed out of his obstinacy, and has ever since taken his food voluntarily. He seemed himself to be tickled by a sense of the absurdity of which he was guilty. Not a doubt of his complete insanity was entertained by my acute companion, who has devoted much observation to the case. Shortly after we had quitted him, and were out of his sight, he put away his knitting, placed his hands in his jacket-pockets, and walked very rapidly to and fro, his face bent on the ground, and he was apparently somewhat excited. Whatever may have been the state of McNaughten at the time to which our inquiries have been directed in this article, we entertain little, if any, doubt that he is now in an imbecile condition."

As illustrative of some remarks we made in a previous number of this journal (October 1850), when commenting on the trial of Pate, we extract also Mr. Warren's description of a conversation he had with Oxford, another criminal lunatic:—

"Oxford was in another part of the building, standing alone, at the extremity of a long corridor, gazing through a heavily-grated window, towards the new House of Parliament. His hat was on; he was dressed like McNaughten, and his jacket was buttoned. We scarcely recognized him, owing to the change of his dress. He is fond of attracting the notice of anybody; and conversed about himself and his offence in the most calm and rational manner conceivable. He has lost much of his hair—a circumstance which he appeared somewhat to regret—for the front of his head is bald; but he looks no older than his real age, 30. He is morally weary of his confinement, and says he has been terribly punished for his 'foolish act.' 'Foolish!' we exclaimed, 'is that all you can say of your attempt to shoot her Majesty?' He smiled, and said, 'Oh! sir, I never attempted to shoot her; I never thought of such a thing. I aimed at the carriage-panels only.' 'Then why did you put balls in your pistols?' 'I never did,' he replied quickly; 'I never dreamed of such a thing. There were no balls.' 'Oh! then you have not heard of the discovery that has just been made—eh?' 'Discovery! what?' 'The bullets.' 'Oh! there have been more found than ever I used, at least; for I assure you I never used any.' 'What made you do what you did?' 'Oh! I was a fool; it was just to get myself talked about, and kick up a dust. A good horsewhipping was what I wanted,' he added, with a faint sigh. These were his very words. 'Should you have done it if you had thought of coming here?' 'No, indeed, I should not; it has been a severe punishment. I dare say public opinion says nothing about me now; I dare say it thinks I have got what I very well deserve—and perhaps I have; but possibly if I were put quietly out of the way, and sent abroad somewhere, public opinion might take no notice of it.' He has taught himself French, Italian, and German, of which he has a fair knowledge. He also used to draw a little, and began to write a novel; but it proved a sorry affair, and being discouraged, he threw it up. 'Do you recollect hearing the condemned sermon preached to Courvoisier?' Oh! yes, very well. It was a most excellent sermon.' 'Did Courvoisier seem to attend to it?' 'Oh! yes, very much; and he seemed very much affected. It was certainly a very appropriate sermon; I liked it much.' 'Did not you think that it might soon be your fate to sit where he was?' 'What! in the condemned seat.' 'Yes.' 'Oh! no; that never occurred to me. I never expected to be condemned for high treason. Some gentleman—I forget who he was—said I should be transported for fourteen years. I thought that was the worst

they could do to me; for I knew I had never meant to do any harm, nor tried to do it.' 'Yes, but the judge and jury thought very differently.' Oh! I was very fairly tried; but I never expected to be brought in mad. I was quite surprised at that, for I knew I was not mad, and I wondered how they were going to prove it.' We asked him if he had ever seen us; to which he replied, gazing steadily, 'Yes, I think I have: either at the Privy Council or in Newgate Chapel.' 'Where did you sit on the Sunday when the condemned sermon was preached to Courvoisier?' 'I sate on the steps near the altar.' 'How were you dressed?' 'Oh! a blue surtout, with velvet collar,' and he proceeded to describe his dress almost exactly as we have described it at the commencement of the article. He exhibits considerable cleverness. Whatever he does, whether in playing at fives or working (making gloves, &c.), he does far better than any one else, and shows considerable tact and energy in setting his companions to work, and superintending them. He admits that he committed a very great offence in having done anything to alarm the Queen, and attributes it entirely to a mischievous and foolish love of notoriety. He said, 'I thought it would set everybody talking and wondering, but never dreamed of what would have come of it—least of all that I was to be shut up all my life in this place.' 'That list of conspirators, and letters from them, that were found in your lodgings—were they not real?' 'Oh! no,' he replied, with rather an anxious smile, 'all mere sham; only nonsense. There was never anything of the sort.' 'Then, why did you do?' 'It was only the folly of a boy; I wasn't 19 then—it was very silly, no doubt.' 'And their swords and dresses, and soforth—eh?' 'Entirely nonsense. It was a very absurd joke; I did not think it would come out so serious. I did not appreciate the consequences, or I never would have done it.' The word 'appreciate' he used with a very marked emphasis. We entertain no doubt whatever of his perfect sanity; and if so, as his crime was great, so his punishment is fearful."

TO DR. WATERS OF PARSONSTOWN.

My dear Sir,—Having just received an official notification that the Association of Medical Attendants to Dispensaries, &c., is to have the advantage of your valuable services as Honorary Secretary, vice Dr. Alexander Knox, promoted to the situation of Medical Inspector of Dispensaries, &c., I avail myself of this medium as being the most likely means of attracting the attention of those who are concerned in the subject upon which I address you, and respectfully take leave, through you, to lay before the Medical Officers of Dispensaries and Fever Hospitals the fact of the Association being indebted to Dr. Knox in the sum of £19 16*s.* 6*d.*, being a sum expended by him (in addition to a subscription of £25) in carrying out the views of the Association whilst watching the progress of the Medical Charities' Bill through the House of Commons.

It is (I am satisfied) but necessary to make this circumstance known to ensure the immediate reimbursement of the amount; to effect which, I would suggest that a circular be addressed by the county secretaries to the medical officers of their respective districts, calling for their subscriptions; and whilst thus fulfilling the old adage, of being "just before generous," I am satisfied that I am but anticipating the expression of the feelings of our entire body, when I assume that in liquidating our *pecuniary* obligations to Dr. Knox, we should avail ourselves of the opportunity thus afforded of discharging those of *gratitude* for the effective services rendered by him whilst acting as our agent in London. I would, therefore, respectfully suggest, that in forwarding their contributions to discharge the £20 debt, each medical officer should include his subscription towards the fund for purchasing a suitable presentation; that Dr. Morrison be appointed treasurer of the fund, and when a sufficient amount be collected, that it shall be laid out as a testimonium committee shall decide.

If I might suggest the amount which each should subscribe, I would say 7*s.* 6*d.*; which, if as generally contributed as I reckon upon, would enable the committee to purchase a piece of plate worthy of Dr. Knox's acceptance.

Hoping soon to receive your summons for the formation of a "National Medical Protective Association," the necessity for which is every day becoming more urgent, I have the honour to be, dear sir, yours very truly,

Percy Swan Waddy,
Dispensary, Broadway, Wexford.

December 27, 1851.

APPOINTMENTS.

Maurice Corr, Esq., F.R.C.S., M.D., has been appointed Medical Superintendent of the Government Convict Establishments at Spike Island.

Alexander Knox, Esq., F.R.C.S., M.D., of Strangford; Thomas Dillon, Esq., F.R.C.S., M.D., of Castlebar; J. F. Purcell, Esq, F.R.C.S., M.D., of Carrick-on-Suir; John Hill, Esq., F.R.C.S., M.D., of Dublin; and W. J. Geary, Esq., of Limerick, have been appointed Medical Inspectors in conformity with the provisions of the Dispensary Act.

M. W. HANLON, M.B.

WHITE'S SACCHARIZED HYDRATE OF MAGNESIA.

The attention of the Medical Faculty is respectfully called to this Preparation of Magnesia as it is becoming known to the Profession. Some of them have prescribed it and found it particularly useful for delicate persons and children. The Magnesia in this preparation being in the state of an Hydrate, consequently will unite with the acid of the stomach without producing any disturbance or uneasiness. Other preparations of this Medicine have to be decomposed, and Carbonic Acid liberated before uniting with the acid of the stomach. This in some cases is found very troublesome. It is to obviate this that the Manufacturer has introduced this Preparation, which, from its peculiar property, will unite with the weakest, and consequently cannot accumulate in the system. Sold in Bottles, 1*s.* each.

JOHN GEORGE BOILEAU and CO.,
Wholesale Druggists and Manufacturing Chemists,
Sole Wholesale Agents,
26, MARY'S ABBEY (Capel-street), DUBLIN.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coreter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT
is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

Bleeding, Cupping, the Application of Leeches, &c.

G. O. and Co. continue to be supplied with the Foreign Mineral Waters Fresh from their various Springs.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 3, will be published, price Sixpence, free by post, each volume complete in itself,
Enlarged to twenty-four folio pages,
The First Number for 1852, of the
GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;
A Weekly Record of Rural Economy and General News.
The Horticultural Part Edited by Professor Lindley.

The Farming Part (under the Editorship of a Practical Farmer) treats of—

The Practice of Agriculture,	Management of Stock,
Agricultural Science,	Veterinary Science,
Animal and Vegetable Physiology,	Drainage,
Improvements in Implements, described by woodcuts whenever requisite,	Irrigation,
Better modes of Husbandry,	Foresting,
Results of Experimental Farming,	Road-making,
Growth and Rotation of Crops,	Farm Buildings,
	Labourers.
	Treatment of Poultry,
	Agricultural Publications,

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are
Weekly Calendars of Gardening Operations,
Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It, moreover, contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make *The Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive *record of facts* only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions: their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any Newsvender.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

SURGICAL SOCIETY OF IRELAND.—Dec. 20.

Mr. Trant, President of the College, in the chair.

SOME PRACTICAL OBSERVATIONS ON PELVIC ABSCESSES.

By Fleetwood Churchill, M.D.,
Fellow of the King and Queen's College of Physicians, Ireland, &c. &c.

Mr. President,—It is impossible to witness the operations of a great Society like the Surgical Society of Ireland, gathering together in harmony the different branches of the profession, and by their united zeal, intelligence, and experience, furnishing an amount of professional information of exceeding value; it is impossible, I say, to see this, and to come within the sphere of its influence, without wishing to contribute something, even though it be only a mite, to the great cause of medical and surgical research. This must be my apology for appearing before you to-night, for I have nothing new, either in theory or practice, to lay before you, no general views of disease, nor any startling novelty in treatment. Indeed, in offering you some practical remarks on pelvic abscesses, I have no doubt of learning much myself from the experience of your members; and if I elicit the information I expect, my object will be attained, and I have no doubt my apology will be accepted.

The peculiar disease, then, to which I would very briefly call your attention is that phlegmonoid inflammation which by some is termed pelvic abscess, and by others inflammation and abscess of the uterine appendages, according as the attempt is made to be more or less explicit. Of the nature of the disease, there is no difference of opinion among modern writers; the older ones, indeed, regarded it as a metastasis of the milk, and termed it "milk abscess."

I have no doubt that the attack is much more common than is even yet believed, although the attention of the profession has been latterly a good deal directed to the subject by writers in Dublin, London, Edinburgh, and France. Within two months this year, for example, I was called to three such cases.

We find this local inflammation occurring under very different circumstances, some of which we should hardly have anticipated.

1. It may occur, not only unconnected with parturition, but in unmarried persons at different ages, and independent of all the ordinary irritants of these organs. A case occurred in the person of one of the nurses at the Meath Hospital, a single woman, about 50 years of age, and without apparent cause. It exhibited the usual symptoms which I shall notice by and by, and ran the usual course, softening and opening into the rectum, after which the patient recovered.

2. I have seen several cases of the disease in married women who never had had children; in two instances it occurred within a few months of marriage; in both the tumefaction was considerable, but both terminated in resolution.

3. In some few cases, it occurs as a secondary complication of severe uterine irritation, apparently from the use of local irritants, the too frequent employment of the uterine sound, the introduction of the pronged pessary, &c.

4. I have seen the disease follow a smart attack of ephemeral fever several times; in one case it terminated in resolution after several weeks; in another in suppuration and evacuation by the rectum; and a third is at present under treatment.

5. It not unfrequently complicates or terminates an attack of simple hysteritis, of which several examples have come under my notice, terminating most generally in suppuration. One such case was the largest abscess of the kind I have ever seen, occupying about one-fourth of the abdomen; and in another, at present under my care, the tumour acquired the size of an orange, and after remaining stationary for some months, is now nearly resolved.

6. In certain epidemics of puerperal fever, inflammation of the uterine appendages appears as a special variety, with or without a corresponding affection of the uterus.

It is not unlikely that the disease may occur under other circumstances, but these have each and all come under my own observation, and I can therefore vouch for their accuracy.

With regard to the nature of the disease, as I have said, there is no difference of opinion, it is a phlegmonoid inflammation of these parts, but there is a distinction of some practical value as to the locality and the parts affected. In this respect all the cases I have seen may be divided into two classes:—

1. The first and largest exhibits a tumour just above the brim of the pelvis, and closely connected with it, fixed and immoveable, extending downwards internally outside the vagina, through the sides of which it can be felt.

2. In the second class the tumour is distinct from the pelvis, rounded, and quite moveable in every direction.

In the latter cases, the inflammation appears limited to the uterine appendages—*i.e.*, the ovary, broad ligament, and Fallopian tubes. In the former, the soft parts which line the anterior and lateral wall of the pelvis are also involved in addition to the uterine appendages; these are more properly named pelvic abscesses.

I may add, that although either side indifferently may be affected, I think the left side is more frequently the seat of the inflammation.

As to the causes of the disease, it is not easy to be very precise.

1. In certain cases to which I have alluded, the abscess is undoubtedly the result of mechanical injury, and the cause is quite intelligible.

2. In others, again, there would appear to be a sort of metastasis of inflammation from the uterus, which in these cases occurs towards the termination of the uterine affection.

3. In a third class of cases, especially when the patient is unmarried, it seems more fairly attributable to cold than to any other cause; but what may be the influence which determines the attack to this region, it is quite impossible to say. In one of the cases to which I have alluded, all the uterine functions had been some time quiescent.

4. Lastly, in puerperal epidemics, when the uterus is involved, we could hardly expect that its appendages would escape; and accordingly we find that they generally share in the disease, though much more remarkably, in some epidemics than in others. In another place I have given statistics of the comparative frequency.

Now, with regard to the symptoms, I must beg you to bear in mind what I have said as to the two varieties of the local affection; the one involving the soft parts lining a portion of the pelvis, and the other limited to the ovary and its appendages, strictly speaking.

The disease may, and generally does, I think, commence by a febrile attack; but this is not always the case. There may be a rigor, followed by heat, or this may be entirely absent. Sooner or later the patient complains of pain or uneasiness in the lower part of the abdomen; but the amount of suffering varies a good deal, and pretty much in accordance with the amount of fever.

If we examine the abdomen carefully, we shall either find a tumour just above Poupart's ligament, of varying size and thickness, and firmly fixed to the pelvis, or a moveable tumour, rounded, firm, and elastic, lying above the pelvis in the abdomen.

In the former class of cases, a vaginal examination adds nothing to our information, as the tumour is out of reach; but in the latter, we can trace it extending more or less down into the pelvis, adding a lateral thickness, extremely tender on pressure. Generally speaking, the uterus is pushed a little to one side, is not tender on pressure, but moving it gives pain. In one or two cases I have seen the uterus fixed and nearly immoveable; in one case only have I seen both sides affected. This occurred in a married woman, unconnected with delivery.

In the former class, also, in addition to the pain, tenderness, &c., the movements of the leg of that side are affected; the patient cannot stretch it out straight without great pain, nor can she walk or stand up without bending forward.

In the latter cases the movements of the limb are quite unaffected. This distinction is, I think, of considerable practical value.

The tumour, I have said, varies in size; it is, however, always tender on pressure, and not less so as the disease advances. When it attains a considerable size or is attended with much irritation, I have seen the bladder and rectum sympathetically affected; the former more frequently so, giving rise to a frequent desire to evacuate their contents. In only one case have I had reason to believe that the tumour offered a mechanical impediment to the passage of the fæces.

These, sir, are the principal symptoms present in a simple case of pelvic abscess; but they, as well as the course of the disease, will vary much according to the extent of the local affection, the amount of constitutional disturbance, and, in some degree, according to the circumstance under which the attack has occurred.

1. In some cases I have seen, the affection had a purely local character. There was the tumour tender, firm, moveable, or immoveable; but the pulse was scarcely quickened from beginning to end; the appetite but little affected; the bowels regular, &c. The patient was confined to the sitting or recumbent posture, and suffered pain locally, but that was all.

2. In other cases, the local suffering was very considerable and unceasing; the pulse very quick, at least 120, with sweating at night; utter loss of appetite; irregularity of bowels; no sleep, and great emaciation.

3. Lastly, the cases which occur during an epidemic of puerperal fever will present its general characters in addition to the local symptoms already mentioned.

With more or less of these symptoms, but with the local ones always, the disease runs its course not quickly; often, on the contrary, very slowly, but with an uncertain duration in each case. I do not think I ever saw the tumour disappear or suppurate in less than a month; and I have known it run on to three or four, as in two cases at present under my care.

The disease may terminate either by resolution or suppuration.

1. By resolution. I have seen repeated instances of this termination, both when the tumour is free and when it is attached to the pelvis, though more frequently in the former than in the latter, and much more frequently in those cases where there is but little constitutional irritation. In such cases, the tumour may increase to a certain degree with the symptoms I have described; it then remains pretty stationary for a time, often a considerable time, after which it gradually and slowly subsides. It is worthy of notice, that if the patient be imprudent during this process, the morbid action in the tumour may be reëxcited, and the case may terminate in another manner. In one of my cases the tumour had nearly disappeared when the lady's servant became suddenly insane, and so frightened her that the tumour enlarged, and all the symptoms reappeared. The time occupied by the process of resolution is generally considerable. I have two cases under my care at this moment illustrative of this; in one, the tumour, which was free, has all but disappeared, after nearly five months; and in the other, the fixed tumour has considerably diminished after three months.

2. In the majority of cases, however, the tumour suppurates, softens, generally perceptibly, and after a process of absorption of the intervening tissues, terminates by the evacuation of the purulent matter; this formation of matter being generally, though not always, marked by the occurrence of rigors. The channel through which this takes place varies a good deal.

1. In some cases it has been evacuated into the peritoneum, giving rise to peritonitis; but this must, I think, be very rare—at least in upwards of twenty cases which have come under my notice it never occurred. I recollect a case which occurred to my friend the late Dr. Haughton, which now appears to me to have been a case of the kind. The poor woman had recovered badly from her confinement, and some time afterwards, when at the night-chair, she felt something give way, and peritonitis immediately followed.

2. Cases are on record in which the abscess opened into the bladder. If I mistake not, I saw one recently in one of the journals; but such cases I believe to be the most uncommon of all.

3. The tumour may soften at its lower part, and the matter may find its way through the coats of the vagina, and be discharged through that canal. I have seen several cases of this termination, the results of which have been very favourable. It has been suggested that we should puncture the tumour in this situation, when the situation of the softening is suitable; nor do I see any objection to the plan. I have, however, not found it necessary.

4. The most common situation, certainly, for a spontaneous opening, is into the rectum, and then the matter will be found discharged along with the stools. On this account, when the tumour is observed to become softer, and we have reason to suspect that matter is formed, the alvine evacuations should be carefully examined. Except when the matter escapes into the peritoneum, no degree of pain seems to accompany its evacuation. It often passes unobserved by the patient, and sometimes seems marked by a sense of relief in the tumour.

5. In a considerable proportion of cases, the tumour approaches the surface gradually and engages the integuments, which become tense, fixed, and sometimes red and shining. Then fluctuation can be felt, the intervening integument is absorbed, and the matter points, as it is called.

The extent of these abscesses superficially, is generally not much beyond the size of the tumour at an earlier period, but in some cases I have seen them very large; in one case, scarcely less than one-fourth of the abdomen seemed involved. I do not think it would be wise to wait for such an extent of disease, but we ought to open it at an earlier period, and thereby save the patient much suffering.

The symptom which most surely indicates this mode of termination, or rather this locality, is the skin becoming fixed over the tumour, not rolling freely, but being adherent to it.

Diagnosis.—There can hardly be any difficulty in the diagnosis of pelvic abscesses which occur after delivery, and as a part of a more general puerperal affection; the attention being directed to the uterine system, a careful local examination will detect the tumefaction, whether it be fixed or not. If it be situated deep in the pelvis, and scarcely appearing above the brim, still the pain down the leg, and the difficulty of extending the limb, will leave but little doubt.

Perhaps an equally careful examination might be equally successful in the unimpregnated condition; but as the disease is not generally expected under such circumstances, a less minute investigation may, and often does, lead to a false conclusion. I have myself known a case of pelvic abscess pronounced to be a fibrous tumour by very competent authority.

Now, the pathognomonic symptoms are, the pain in the tumour and down the leg, the impossibility of standing quite upright, or extending the leg completely, and the tumour detected on external and internal examination.

1. From fibrous tumours it is distinguished by its comparatively quick growth, the amount of uneasiness, and the termination. The former increase very slowly, and insensibly give rise to few or no symptoms, and, above all, are not common in the uterine appendages.

2. In women of a certain age, the filling up more or less of the pelvic cavity, might be supposed to result from cancerous deposition; but here we have no general cancerous diathesis, the uterus is always unaffected, and the occurrence of suppuration or resolution solves the difficulty.

3. That one variety of abscess which is unconfined resembles much ordinary ovarian enlargements, at first sight, but it differs in this, at least according to my experience, that it never occurs except in connexion with childbirth or miscarriage; and, as a general rule, the growth is much more rapid in the cases under consideration.

The affection, then, may be considered as well marked, and, with care, not difficult of appreciation, but requiring special care and attention when it occurs independent of parturition.

Prognosis.—For so serious an attack, involving such important organs, and liable to such various terminations, the prognosis is very favourable. I have seen more than twenty such cases, and have never seen one in which any unpleasant result occurred. Some fatal cases are on record, but they must be very rare, and probably in consequence of secondary peritonitis.

The disease is, however, very tedious, and may reduce the patient considerably, so that there may be some risk of the incursion of other diseases, if the patient be predisposed thereto.

Treatment.—Whether the attack come on after delivery or independent of it, if we see the patient during the acute stage, it will be necessary to apply leeches over the tumour, to repeat these, if required, in numbers according to the amount of irritation and the patient's strength, and to follow them by constant poulticing.

The bowels should be kept quite free, and I have found benefit from small and repeated doses of calomel or blue pill, but not continued so long as to affect the gums.

The diet of the patient during this first period must be low, and I need hardly say that she must be confined to bed.

After we have somewhat subdued the acute inflammation, we must still continue the poultices until suppuration is established; but if the pulse be quiet, we may allow a little better diet, such as chicken-broth or beef-tea.

When we are satisfied that suppuration has taken place, that matter is formed, then our anxiety is as to the place where it is to be evacuated. If by the bladder or intestine, we can do nothing but continue the poultices; but if, on a vaginal examination, we find the tumour soft and the intervening parietes thin, we are advised to make a puncture with a bistoury into the tumour, first ascertaining the presence of pus by an exploring needle. If we succeed, the after-treatment is simple; so long as purulent matter escapes, the poultice may be continued, and occasional pressure made upon the tumour, so as to empty it as much as possible.

But if the tumour enlarges above Poupart's ligament, involves the skin, and becomes soft, with a sense of fluctuation, it must be opened freely in this situation; and it will save the patient some suffering if we make an incision reasonably early. Sometimes a large amount of matter is discharged with great relief, sometimes only a small quantity, but the discharge will continue so long as suppuration goes on. When it ceases, the poultices may be omitted, and some dressing substituted if the wound remains open.

When once the abscess is opened, we may allow the patient a more generous diet, with wine, &c., and in many cases bark may be given with benefit.

But if the tumour shows a disposition to resolve itself, it will be advisable by degrees to leave off the poultices, and substitute cotton wool or flannel. In some cases this process is hastened by a small blister applied occasionally, or by painting the part with strong tincture of iodine, and I have seen great benefit and improvement result from warm hip-baths twice or thrice a week.

Such, Mr. President, is the imperfect sketch I have ventured to lay before you. No one can be more sensible than I, that it needs an apology, and I trust it will be found in the fact, that it has been written in the midst of great anxiety and hurry, without time to refer to books, and from an earnest desire to show my willingness to coöperate with you in your noble efforts to advance the science of medicine and surgery.

Dr. McClintock observed that from time to time he had seen a few examples of pelvic abscess, and that his own experience fully confirmed that of Dr. Churchill. He had seen cases in which the abscess had presented internally into the vagina, and into the rectum; but if he were to confine himself to his own experience alone, he would

say that the most usual direction was externally. It was also worthy of remark, that in none of the cases that had fallen under his observation, did a fatal result ensue—a circumstance which was corroborated by the testimony of Dr. Churchill. In most of the cases, the abscesses appeared to him to have some connexion with uterine inflammation, and they occurred very frequently in patients who exhibited a slight tendency to metritis, or who did not get on well during the first week after delivery. He likewise noticed that in the majority of cases, the abscesses made their appearance at the left side. The curious fact had been commented on by Dr. Churchill in his present valuable communication; but it should be borne in mind that it was not confined to pelvic abscesses following delivery. The same thing had been observed to take place in the eye, when attacked by puerperal inflammation in that destructive form known under the name of "ophthalmic phlebitis." In such cases, and he had met with two instances in his own practice, it was almost invariably the left eye which was affected; and Dr. Marshall Hall had made a similar observation with respect to the cases he had recorded. Again, he believed that phlegmasia dolens was more commonly found in the left leg than in the right. It was certainly a most remarkable fact, but it was, he thought, questionable whether any good could arise from conjectures offered in the way of explanation. Some authors seemed to think that this tendency towards the left side might be ascribed to the very general practice in this country, of delivering women on the left side; but this idea could not, with any show of reason, be maintained, since, in France and Germany, women were invariably delivered on the back, and yet the experience of medical practitioners in both of those countries confirmed the fact, that the abscesses were generally found at the left side.

Dr. H. Kennedy begged leave to refer very briefly to one point referred to by Dr. Churchill in his interesting paper—namely, the question of diagnosis. He had not been so fortunate as to meet with many cases of pelvic abscess, but if he might judge from the few he had seen, he would be disposed to say that the diagnosis of abscesses in this situation was by no means such an easy matter as the author of the present communication would have them suppose. In fact, he always experienced difficulty in arriving at a positive conclusion as to the precise nature of the case; that is before a tumour could be felt. In one particular case, which occurred some time ago, the diagnosis of the disease was literally impossible. It was that of a young girl, aged 16, who fell across a tub and injured herself in the left iliac fossa. Shortly after the accident she was admitted into the Whitworth Chronic Hospital, at which period she was labouring under a slight degree of fever, and some uneasiness in the left iliac region. At the end of a week, however, the fever ran very high, and resembled very closely the kind of fever met with in cases of what was usually termed acute phthisis. At the same time the sufferings of the patient became intense, the pain being referred to the left iliac region. By and by, some of the signs of tumour made their appearance; very obscurely in the first instance, but gradually became more and more decided, until at length no doubt could be entertained that a tumour existed in this situation. It was more or less of a floating character, and might with greater propriety be called an abdominal, than a pelvic, tumour, having regard to the locality in which it was felt. The amount of pain on pressing it was inconsiderable; but the pressure was followed by a good deal of suffering, and at times the agony of the patient became most intense. In this way seven or eight weeks passed over, and at length the fever ran still higher, and was attended by delirium; in which state the girl speedily sank. Now, it was worthy of remark that during the progress of this case, various opinions were hazarded as to its nature by the medical gentlemen who had seen it; and yet nothing like an accurate diagnosis was made by any one during the lifetime of the patient. After her death, it was discovered that the ovary was the seat of the disease. Disease of a malignant character had attacked the organ, which had become as large as a kidney of the largest size; and on cutting into it, it proved to be an excellent specimen of fungus hæmatodes. It was subsequently exhibited to the Medico Chirurgical Society, which was then in existence, and he thought the case worthy the attention of the Surgical Society, as an instance of the difficulty of arriving at a correct diagnosis in certain cases, owing to the locality of the tumour and other circumstances connected with it.

MEDICAL SOCIETY OF LONDON.

EXTERNAL DIVISION OF STRICTURE OF THE URETHRA.

Mr. Coulson related the following cases of cure of impermeable stricture by Mr. Syme's operation:—Wm. J——, aged 44, a sailor, was admitted into St. Mary's Hospital, October 13, on account of great difficulty in passing his urine. Eight years ago, he had stricture, but did not suffer much from it till the beginning of 1849, when he met with an accident, at which time he was seized with retention of urine, and has suffered from it occasionally ever since. At the time of his admission, he passed his urine sometimes in a very fine stream, at other times drop by drop. On passing an instrument into the urethra, a firm obstruction was met with five inches down, through which no instrument could be passed; just anterior to this there was a false passage. There was no induration beyond the stricture, nor any perineal fistula. The man had been in one of the largest metropolitan hospitals for some time previously, but no passage could be effected through the stricture. Under these circumstances, Mr. Coulson thought the case a favourable one for operation, and on the 15th of October, he divided the stricture through the perineum. A grooved staff was introduced down to the stricture, and the urethra opened just above it, immediately below the scrotum, for an inch and a half; the stricture was then divided, and the staff readily entered the bladder. This was withdrawn, and a No. 8 silver catheter introduced, and retained in the bladder forty-eight hours. There was some little difficulty in the operation, for no instrument being passed through the stricture, there was no guide to the urethra beyond the contraction. Another cause of difficulty was the existence of the false passage, for the staff, on being pressed against the stricture, had a constant tendency to go in the wrong direction. Mr. Coulson said that he might probably have passed a No. 1 grooved staff through the stricture; but he made fewer attempts than he otherwise would, in consequence of the false passage, and his having frequently opened the urethra easily, without the assistance of a staff. There was a good deal of bleeding after the operation, but it stopped in the evening. A No. 8 silver catheter was introduced every third day, whilst he remained in the hospital, and retained half an hour at each introduction. The patient had not had a single bad symptom; the wound healed readily, and the patient was discharged at the end of five weeks. Mr. Coulson said that he had seen the patient two days ago, and the largest-sized catheter could be easily passed into the bladder.—The second case was that of a patient, aged 54, who had laboured under stricture nearly thirty years. It had been divided by the lancetted stillette, and periodically dilated; but during the last two years it had become so much contracted, as not to admit a No. 1 bougie. The water came away only drop by drop; and at times retention occurred, which was always relieved by the application of the potassa fusa. Mr. Syme's smallest grooved staff was passed, and an incision an inch and a half in length was made, commencing from close to the scrotum, and carried down towards the anus. The groove of the staff was at once reached, and the stricture divided. A No. 8 silver catheter was introduced, and a considerable quantity of fœtid, alkaline urine discharged. There was a little bleeding in the night, which was easily stopped by pressure. The catheter was retained in the urethra forty-eight hours, and introduced every third day for a fortnight, at the end of which time this patient was able to leave the house, and resume his duties in a large newspaper estab-

lishment. At the present time, the largest catheter (No. 10) which the orifice of the urethra will admit, passes readily into the bladder. Mr. Coulson stated that he had operated on other cases, but he would bring them before the Society on another occasion. Mr. Syme's direction of the performance of the operation, is, that a grooved director, slightly curved, should be passed through the stricture; and the surgeon, sitting, or kneeling on one knee, should make an incision in the middle line of the perineum or penis, wherever the stricture is situated. The incision should be about an inch or an inch and a half in length, and extend through the integuments, together with the subjacent textures exterior to the urethra. The operator is then to feel for the stricture, and introduce the knife, or small, straight bistoury, behind or on the bladder side of the urethra, dividing, from behind forwards, the whole of the contracted portion. Mr. Coulson said that many severe cases of stricture will yield to persevering efforts at dilatation, or the use of the potassa fusa, or the ingenious and valuable instruments of Mr. Thomas Wakley; but every now and then cases will occur which resist all these means. Some years ago he had published several cases of stricture which he had cured by the lancetted stilette, after the failure of attempts at dilatation and the use of caustic, but there is an uncertainty in the use of this instrument which does not exist in the operation recommended by Mr. Syme. He said that, among the many and great obligations under which Mr. Syme had placed the profession to him, not the least was that of having recommended an operation so easy of performance, and so effectual, for the class of cases to which those he had mentioned this evening belonged.

GALVANIC BATTERY AND BELT.

Mr. PIGGOTT exhibited his battery and belt, and also explained their action. He said, that in all cases in which it was desirable to apply galvanism, the great desideratum has been to procure a continuity of the galvanic current of low tension or quantity, as distinguished from intensity. This could not be obtained by any of the ordinary acid batteries, the galvanism obtained from them being intense, and therefore inappropriate for curative purposes. In the application of Mr. Piggott's battery, the current of low tension is easily converted into intensity at the will of the operator; the battery is, so to speak, a self-acting one, and requires no previous preparation before using. It presents the appearance of a square box of polished mahogany, and varies in size from six to twelve inches square. Mr. Piggott stated that his battery was constructed with the ordinary metals, which were permanently separated by a porous diaphragm, saturated with deliquescent salts, which latter, absorbing the moisture of the atmosphere, excited an electric current always ready to be called into action. The galvanic belt is made on the same principle, and when used emits a continuous current of electricity, which, passing through the patient, stimulates the nervous system in a highly beneficial manner. The belt is called into action as soon as it is applied, and may be worn without needing saturation, and in fact without the slightest moisture being necessary. Mr. Piggott also mentioned that in several cases of contracted limbs he had used the galvanic battery in the first instance, and then applied the belt, made in the shape of knee and leg bands, with complete success. He had also successfully applied it to cases of neuralgia, dyspepsia, and disorders arising from an inactive state of the nervous system. The belt can be so constructed as to be applicable to any part of the body—viz., wrists, arms, limbs, neck, &c.—*Lancet.*

RELIEF OF PAIN BY COMPRESSION.—Dr Turck of Plombières has published a series of cases in which great relief was obtained by compressing, for a longer or shorter time, one or both carotids (or rather pneumogastric nerves). Severe colic, without diarrhœa, of fifteen years' standing, incipient phthisis, gastralgia, sciatica, &c., were temporarily benefited by this compression. Dr. Turck was induced to try this peculiar therapeutical means as it had, according to some authorities, in England and France, rendered good service in facial neuralgia.

PATHOLOGICAL SOCIETY OF LONDON.

DR. QUAIN presented specimens from a case of

CANCER OF THE LUNGS, PLEURA, PERICARDIUM, BRONCHIAL, AND OTHER GLANDS,

and gave the following history of the case, as obtained by Mr. Dickinson of the Brompton Hospital:—A. M——, aged 50, a servant and a widow, having had two children, was admitted into the hospital under the care of Dr. Cursham, on October 13th. She had always lived well, and enjoyed good health, save that seven or eight years ago she vomited considerable quantities of blood. This attack appeared to have been connected with some derangement of the menstrual function. Her present illness came on seven months before her death, when she was attacked with cough and slight expectoration, with occasional pains in the chest. From this time she began to lose flesh, her appetite failed, and for the last two months she had had œdema of the legs, for which she had been subjected to acupuncture. On admission she was pale and sallow, complaining of pain in the chest, troublesome cough, with scanty expectoration of a serous character, and great dyspnœa, which prevented her from lying down at night. She had pain in the legs, which were œdematous, and discharging, through an ulcer on each, a considerable quantity of fluid. She slept badly, and had a bad appetite; bowels rather confined; catamenia had ceased for the last two years; hair black; eyes gray; fingers not clubbed; pulse 68; respirations 32; felt very weak and low; was very irritable, obstinate, and anything but communicative. On examining the chest, the right side was found to move but little. It was an inch and a half more in its circumference than the opposite. There existed great and universal dulness over the whole side. The vocal vibration was not felt, and respiration was not heard below. Over the upper parts of this side, more especially behind in the supra and intra-scapular regions, there was a remarkably loud bronchial breathing with bronchophony. On the left side, there was dulness and a peculiar prolonged respiratory murmur. Over the heart there was heard, with the impulse, a rough, almost rasping sound. She continued to get worse; about ten days before her death the left arm became considerably swollen and œdematous; the dyspnœa increased; and, after about a month's stay in the hospital, she gradually sank.

Post-mortem.—Body not particularly emaciated; œdema of the left arm as high as the elbow, and of both legs as high as the hips; on the outer side of the left leg was a simple ulcer the size of a shilling; and on the right leg the cicatrix of another as large as a crown-piece. The mammæ were atrophied. On opening the chest, the right lung was found adherent to the wall of the cavity at the base by a strong band; at the left side there were some slight old adhesions; in the right pleural cavities there were three pints of sero-sanguineous fluid; in the left, scarcely any. The costal pleuræ on both sides were studded with small, flattened, hard laminæ, varying in size from a split pea to a sixpence; there were also a few calcareous particles the size of peas beneath the costal pleuræ; the right lung weighed twenty-nine ounces, was contracted in all its dimensions, and its surface irregularly studded with small, projecting, firm masses; on cutting into these, the whole lung was found to be closely studded, more particularly at the base, with small masses; these varied in size from a small pea to that of a walnut, and were more distinctly bounded at their margins than are similar masses of tubercle; they felt solid and firm, but were easily crushed between the fingers, and were of a pinkish-white colour; the vessels and bronchi throughout the lung were remarkably patulous. The left lung weighed nineteen ounces, was about the natural volume, and contained several masses similar to those in the right lung, but smaller; there was gray hepatization of a small portion at the base of this lung. The heart weighed eleven ounces; beneath the visceral pericardium, more particularly at the base were observed a number of flattened

from a flattened pinhead to a sixpence; these masses rendered the surface of the pericardium rough, and on cutting into them, they were found to intrude but slightly on the muscular tissue; there was some thickening of the left and right auriculo-ventricular valves, more particularly of the left; above the root of the lungs there was found a large mass of the same morbid matter; this mass extended to, included, and compressed the trachea, and more especially the arteria innominata and the left vena innominata; the thoracic surface of the diaphragm presented several flattened masses on its surface, and a mass of the same matter, as large as an egg, occupied the lower part of the anterior mediastinum. The liver weighed forty ounces, was healthy, but congested; spleen small, weighing but two and a half ounces; pancreas small. The kidneys weighed each five ounces and a half, and were healthy but congested. The mucous membrane of the alimentary canal was much congested; the lumbar lymphatic glands contained matter similar to that described in the lungs; the uterus contained in its substance a small mass of deposit similar to that found in the lungs. Portions of the morbid matter from nearly all the situations in which it existed were examined with the microscope, and found to consist of cells, and a stroma or basis; the fully-developed cells were about twice or thrice the size of blood-globules, generally spherical or oblong, and contained large, well-marked nuclei, granules, and oily particles; some of these cells presented a peculiar appearance—a vacant space from which nuclei seemed to have escaped. The stroma was remarkable for the fineness of the fibres of which it was composed; these were irregularly disposed.

Dr. Quain remarked that this case presented a good example of primary cancer of the thoracic organs. The morbid appearances were very characteristic, and it was well to direct attention to these cases as guiding us to the diagnosis of these obscure affections of the lungs.—*Lancet.*

ON THE TREATMENT OF CURABLE DISEASES.

By W. S. Oke, M.D., of the South Hants Infirmary.

Defective Power of the Lower Extremities in the Second Year of Childhood.

This is a case which often comes under my observation, and which, I believe, has been overlooked. The child, instead of being able to stand at the usual time, is found to be unable to bear the weight of the body on its lower limbs, the muscles of which are in some degree wasted and flabby. Upon examining the spinal column in the sitting posture, a slight posterior curve of the inferior dorsal vertebræ will be discovered, which will at once indicate the cause of the want of power. The following mode of treatment I have commonly found successful: A small blister about an inch and a half long by half an inch broad is to be applied on each side of the curve once in a fortnight; the system is to be supported by prescription No. 1, and the bowels gently corrected once a week by No. 2.

1.—℞ Vini ferri, m. xx.
Detur hœc dosis intanti bis quotidie ex aquæ pauxillo.

2.—℞ Hydrargyri cum creta, gr. ij.
Rhei radicis pulv. gr. iv.
Pulveris cinnamoni comp. gr j.
Misce fiat dosis semel in septimanis sumenda.

The child is never to be carried *upright;* and as it will be of great importance to take it into the open air in fine weather, it may be laid upon a small mattress in a concave wicker tray, which will be found light and convenient for the purpose. When left to itself it should be laid on a mattress either upon the floor or upon a bedstead; and this treatment should be continued until it regains sufficient power to attain the upright posture.

Case.—A lady, on discovering that the lower limbs of her child, although fifteen months old and of healthy appearance, always gave way under the weight of the trunk, brought it to me to ascertain the cause. On examining the spinal column I found a slight posterior curve of the spinous processes of the inferior dorsal and upper lumbar vertebræ. A small blister was ordered to be applied on each side of the curve, half a fluid drachm of the vinum ferri to be given twice a day, and strict directions were given that no further attempt should be made to induce the child to stand upon its feet for some time to come, and that it should be carried into the air in a recumbent position in a wicker tray. The result was, that in a few months it completely recovered the use of its legs, and went on well. Were it necessary, I could adduce very many cases of the same kind to prove the success of this mode of treatment. The strength should be supported, if the child has been weaned, by equal parts of milk and barley gruel.

Convulsions in Children.

Convulsions in children are most commonly brought on by reflex action, from some cause external to the brain, such as teething, crudities in the alimentary canal, &c.; but they are sometimes the result of a congested state of the cerebral vessels, and therefore an early and correct diagnosis is of the highest importance. If they are occasioned by the former, there may be no antecedent cerebral symptoms to warn us of their approach; they will probably soon cease: and moreover some advancing teeth, or improper food, will perhaps at once manifest the exciting cause, and the method of cure. If from the latter, they will be preceded by symptoms of cerebral congestion, such as inaction of the bowels, a drowsy aspect, pain of the head (if the child be old enough to express it, if not, the hands will be frequently carried there), immobility of one or both pupils, involuntary movements of the eyeballs, and grinding of the teeth. Convulsions following these symptoms do not subside like those which are produced merely by the irritation of teething, or of crudities in the stomach; and unless they are combated by a prompt and decided treatment, will continue till the brain becomes oppressed by serous infiltration, which is almost certain to end in insensibility, profuse sweats, intermittent breathing, and death. In this case we ought not to wait for the bleeding of leeches, but should immediately open the external jugular vein, and take away as much blood as the circumstances may require. It may be done in the following simple manner:—Having carried a ligature of tape, or of any thing at hand, around the side of the neck about to be punctured, and under the opposite axilla, sufficiently tight to make the vein rise, the integuments and platysma myoides muscle are to be freely divided by the edge of the lancet, by which the vein will be brought into view, and easily punctured. The best receiver will be a common saucer, the lip of which is to be made to press upon the vein below the orifice. I have frequently seen the greatest benefit from this practice, which I fear is too much neglected in the present day. The scalp should now be shaved, and covered with a bladder half filled with pounded ice, or snow, if at hand. The head and shoulders are to be raised and supported in position by a hard pillow. No. 1 is to be given immediately, and No. 2 in two hours afterwards.

1.—℞ Hydrarg. chlor.,
Scam. pulv. utrq. gr. iij.
Misce. Detur statim in simplice syrupo.

2.—℞ Hydrarg. chlor. gr. ij.
Sacch. purific. gr. v.
Misce. Detur secunda quaque hora.

Should the convulsions not subside under this treatment, and there be reason to fear that serous infiltration has taken place, a large blister should be applied to the head, and strong mercurial ointment, spread on lint, laid along the course of the lymphatic vessels upon the inner surface of both upper arms, but under such circumstances there can hardly be any expectation of recovery.

Cachexia Scorbutica in Children.

Amongst the lower grades of society children are sometimes affected with scorbutic, spongy, and bleeding gums, associated with superficial ulcerations of the membrane of the mouth, fœtid breath, pallid aspect, and very low power, symptoms which have probably arisen from crowded habitations and deficient diet. This wretched state admits of

rapid improvement by the lotion (1), the mixture (2), and a generous diet.

1.—℞ Solutionis chloridi calcii,
Mellis rosæ, sing. oz. ss.
Aquæ puræ, oz. v.
Misce fiat lotio ter die utenda.

2.—℞ Quinæ disulphatis, gr. vj.
Acidi sulph. dilut. gtt. xx.
Tinct. aurantii, comp.
Syrupi zingiberis utrq. oz. ss.
Aquæ distillatæ, oz. ij.
Misce capiat cochlearia parva duo bis quotidie.

The lotion should be carefully applied to the mouth and gums by means of a syringe or camel's hair brush, unless the child be old enough to use it in the ordinary manner. The bowels are to be regulated by rhubarb or castor oil. The diet is to consist of animal broths and a little wine, and the child taken out into the air as often as the weather permits.

Cachexia Verminosa in Children.

This case is characterised by a pallid, half-starved aspect, with attenuation, picking of the nose, morbid appetite, abdominal enlargement, and lumbrici in the alimentary canal. The cachectic condition arises probably from debility of the digestive functions, thereby admitting of the formation of the entozoa. The lumbricus is more commonly met with in the human body than any other worm, and sometimes a considerable number will exist in the intestinal canal of one individual at the same time. A child of five years old, residing in the New Forest, passed seventeen full-sized lumbrici in the course of five days. They are generally voided by the rectum, but occasionally by the œsophagus, and thence through the mouth or nostrils. Gnawing pain in the region of the stomach, a constant craving for food, irritation of the nose, and occasional moving sensations at the upper part of the intestinal canal, more particularly indicate the presence of this worm. This case will be successfully treated by the aperient (1), and the chalybeate (2). The former will sweep out the intestinal canal, and improve the secretions; the latter will not fail to strengthen the depraved condition of the system. A generous diet is indispensable.

1.—℞ Hydrargyri chloridi,
Pulv. scammonii, sing. gr. ij.
Radicis rhei pulv. gr. iv.
Pulv. zingib. gr. j.
Misce et sumatur bis in septimanis in crasso vehiculo.

2.—Vini ferri oz. iij.
Capiat cochleare parvum ex aquæ pauxillum bis quotidie.

If diarrhœa be present, two drops of the tinctura opii should be added to each dose of the vinum ferri, and the aperient (3) be substituted for the purgative (1).

3.—℞ Hydrargyri cum creta, gr. ij.
Pulveris radicis rhei, gr. iv.
Pulveris cinnamoni comp. gr. ij.
Misce fiat pulvis bis hebdomeda sumendus.

Cachexia Syphilitica in Infants.

This depraved condition of the system in infants is not uncommon, and must have been communicated by the parent in utero. Soon after birth there is an acrid discharge from the nares, producing obstruction to the nasal breathing and constant snuffling, which occasions an excoriation of the upper lip. There is also frequently a squamous eruption upon the angles of the mouth, and condylomata around the anus. If the progress of the disease be not arrested, it will extend to other structures, and ultimately involve the bones of the palate, nose, and upper jaw. From these results the auditory function is often obliterated, and the tongue being untutored by the ear, the child will become deaf and dumb for life. This disease is curable by medicine, unless struma be associated with it, and there be set up a strumo-syphilitic diathesis. The mode of treatment would consist of the iodide of potassium and mercurial alteratives, the doses of course to correspond with the age of the child. In infants, the formula 1 and 2 will be sufficient for the system. If there be any eruption at the angles of or about the mouth, it may be smeared, morning and night, with the ointment (3); and should there be condylomata at the anus, the caustic lotion (4) may be applied to them twice a day by means of a camel's hair brush.

1.—℞ Potassii iodidi, gr. xij.
Syr. zingi. oz. iss.
Misce. Detur infanti fluidrachm ter quotidie.

2.—℞ Hydrargyri cum creta, gr. xij.
Pulvis tragacantha comp. dr. ss.
Misce et divide in chartulas xij.; detur una bis die.

3.—℞ Unguenti hydrarg. nit. oxidi, dr. ij.
Utetur mane et nocte.

4.—℞ Argenti nitratis, gr. x.
Aquæ distillatæ, oz. j.
Misce et fiat lotio bis die applicanda.

This treatment is to be continued till the disease has disappeared.

Cachexia ex Alvi Fluxu in Infants.

Cachexia in infants is sometimes the result of long continued diarrhœa, brought on either by a morbid secretion of the mammary function on the part of the mother, or if it arise after lactation by careless and improper food. The child, from this constant out-run from the bowels, is often reduced to an *extreme degree* of attenuation, has a senile aspect with large features out of all proportion to the shrunken appearance of the countenance, and looks like a living skeleton. Although an infant in this state may appear *prima facie* to be beyond the reach of human skill, the contrary is more commonly the fact; for by judicious treatment as to medicine and diet, and above all, by the kind attentions of a nurse, the secretions may be corrected, the diarrhœa controlled, and the health restored. The two first may be accomplished by 1 and 2.

1.—℞ Pulveris ipecacuanhæ comp. gr. iij.
Hydrargyri cum creta, gr. vj.
Confectionis aromat. scr. j.
Syrupi zingiberis, dr. vj.
Misce, et ampulla agitata, detur dr. j. omni nocte alterna.

2.—℞ Tinctura catechu, dr. j.
Spiritus menthæ pip. gtt. iij.
Syrupi simplicis, dr. ij.
Tincturæ opii, gtt. vj.
Misturæ cretæ, dr. ix.
M. Detur cochleare parvum bis terve die.

The food which I have seen attended with the greatest success, is boiled flour and skimmed milk, prepared in the following manner:—Take a sufficient quantity of flour, tie it into a linen cloth, and boil for several hours till it becomes hard; then peel off the outer part and grate the centre into skimmed milk till it becomes the consistence of gruel; add powdered white sugar, and let the child be wholly fed with it until the health is restored.

Cachexia Purulenta in Children.

The species of cachexy here alluded to is the result of long-continued purulent discharge from external causes. The child is pale, emaciated, and almost exhausted, simply by the quantity of discharge. There is no hectic fever, and the case is curable. The following example will show both disease and treatment:—A child of a year old was brought to me a short time ago from the Isle of Wight, with a disease of the os ilii. It was so reduced and attenuated by the constant discharge from several openings, that there did not appear to be any rational hope of recovery; however, I ordered fifteen drops of the vinum ferri to be given to it three times a day, with a nutritious diet. In a month I saw the child again, and there was a remarkable improvement, both in the local disease and in its general health; after about the same interval, it was brought to me the third time, when the openings were almost healed, and the child was convalescent. I am happy to perceive that the London College of Physicians has thought fit to restore the vinum ferri to its place in their new Pharmacopœia, as I have ever found it in the diseases of children requiring chalybeate medicine, a most convenient and effectual preparation.

Cachexia Eczematosa in Children.

This disease is very common amongst the ill-fed and

neglected children of the lower classes. There is a pale and sickly aspect, and on different parts of the scalp the hair is matted together with filthy scabs, of eczematous secretion, from which exudes a thin and irritating discharge. There are also weak ulcerations behind the ears, and about the angles of the mouth, and on the nares, &c. There is no eruptive disease more easily got rid of than this, provided the treatment be carefully carried out. The whole of the scalp having been closely clipped, and the scabs removed by poultice or fomentation, the eczematous parts are to be smeared by the ointment (1) twice a day, and well fomented before each application. The alterative dose (2) is to be given twice a week, and the strength supported by (3). By these means the removal of the disease will be at once accomplished.

OPERATION FOR STRICTURE.

By Mr. Simon of St. Thomas's Hospital.

When once spasmodic stricture has supervened upon the organic form, the case admits of no further delay, and accordingly we find that the most able surgeons have taken especial pains to inculcate the necessity of immediately resorting to some steps for withdrawing the urine. But though there has generally been little doubt as to what we are to do when the catheter can be passed, yet the greatest disunion has long prevailed as to what plan is to be adopted when the instrument cannot be made to penetrate the stricture. One of the most unobjectionable of these has been considered to be the piercing of the bladder through the rectum with a trocar, and yet we find it strongly condemned as dangerous and unjustifiable. Mr. Guthrie says, "the peritoneum, instead of passing down behind the bladder, and between it and the rectum to the base of the triangular space, and then terminating in a cul-de-sac, does sometimes pass on further between the triangular space and the rectum, and even occasionally as far forwards as the prostate gland; so that, by puncturing through the rectum, the general cavity of the peritoneum will be opened in such cases before the bladder is reached, and the patient must be lost." Nor has the operation above the pubes been less condemned. Mr. Guthrie considers this also altogether objectionable; and to quote authorities who have raised their voices against it would only be to fill the pages of the journal with subject-matter which the reader will find in every standard work on surgery. We have several times seen puncture of the rectum with the happiest results, and never seen it fatal or even injurious. The operation above the pubes has been abandoned and resuscitated, till it is difficult to say in what degree of favour it now stands, while that of passing down the catheter to the stricture, dividing this, taking up the urethra again like a lost thread, and passing the catheter on to the bladder, is undoubtedly difficult, sometimes impracticable, and occasionally fatal.

Mr. Syme's operation has undoubtedly succeeded in cases, but then it is adopted, and seems to be only intended, for the radical cure of organic, not the instantaneous relief of spasmodic stricture, and one reason of its success is, that first of all a curved director should be passed through the stricture, and if the patient would most probably die while the surgeon was taking means to cure radically "the unyielding condition manifested by the constricted canal, and its tendency to contract perhaps even more closely than before after being partially or completely dilated." Moreover, the hæmorrhage which follows it is often alarming, and has in some instances been all but fatal. Hence any plan tending to relieve the sufferings of the patient, and render the removal of accumulated urine more easy and safe, as well as less dangerous, will doubtless be welcomed by surgeons as a valuable addition to our resources against this malady. Mr. Simon has in several instances performed a very simple and effectual operation for stricture, which has the additional advantage of being equally adapted to cases of simple permanent stricture and those complicated with retention. Mr. Simon passes the finger of the left hand into the rectum, and feels for the prostate gland: so soon as he has well made out the position of this, he plunges a narrow bistoury into the raphe, about an inch anterior to the rectum, and carries the point of it towards the tip of the finger; the back of the knife is turned towards the finger, and thus the urethra is at once reached, posterior to the stricture. This immediately relieves the retention, and he then allows the stricture time to dilate a little, which it does when the pressure is taken off from behind, and then it can be dilated by the bougie, &c. Mr. Simon has performed this operation in several cases with success. The first case of all was that of a man who was sinking rapidly, the bladder distending, the tongue growing brown, and typhoid, great anxiety, &c., and who would have died before the ordinary operation of cutting down upon the stricture could have been executed. It was accomplished in a very short time, and was quite successful. In the following cases, which we give somewhat in full, it will be seen that the stricture was far advanced, but was unaccompanied by spasm. For the notes we are indebted to the kindness of Mr. Tyrrell of St. Thomas's.

Case 1.—H. L., aged 34, a hawker, was admitted into Lazarus Ward, October the 14th, 1851, with stricture and perineal abscess, of which he gave the following account; He had been accustomed to live somewhat freely, but was not in the habit of drinking to excess. He has suffered under stricture for six years, and two years ago had an abscess in one of his testicles—the result, perhaps, of the stricture. On his admission, he appeared to be in a very weak state: there was an abscess in the perineum, which, according to his statement, had only existed for a week. Distinct fluctuation was made out. The stricture scarcely admitted the smallest catheter, which was passed the next day into the bladder; and the abscess in the perineum was opened, giving exit to a quantity of very fœtid pus. The patient was sent to bed; four ounces of gin were also ordered him, and the opening into the abscess was dressed with linseed meal poultices.

On the 16th, or the second day after admission, he complained of the smarting, and occasionally the urine getting upon the wounded surfaces; he was weak, and had passed a sleepless night. Urine flowed also by the urethra. At half past twelve on the same day he was seen by Mr. Simon; and as there was a good deal of urine extravasated, and a considerable quantity was passed through the catheter when this was introduced, the surgeon decided upon puncturing the canal. This was done in the way we have described, and the urethra was reached with great ease: a firm elastic catheter was then passed into the bladder. During the two succeeding days it was clear that the patient's state became very critical. His pulse was quick and weak; he was feverish and ill, and the urine contained a great deal of pus; but the swelling in the perineum steadily subsided, the pulse gradually rose, the patient began to sleep better, and the urine lost its purulent character.

On the 20th of October it is stated in the report that "the swelling has now almost disappeared; his urine has much improved in every respect; it is clearer and less offensive." As he complained of his bowels not being open since the 17th, half an ounce of castor oil was ordered: and the dressing with warm water, which, for the last two or three days, had been substituted for linseed poultices, was continued. Three days after, he noticed that there was a discharge from the urethra, and he still complained

of being weak and having no appetite, but he was evidently getting stronger, and the abscess was rapidly disappearing. On the 27th, the catheter was withdrawn from the bladder: it was very much coated with phosphates. A small catheter was now passed by the penis into the bladder, and kept there for some little time. The dilatation of the stricture was now commenced, and a succession of bougies was passed with the happiest results. By November 5th, considerable ground had been gained, and very little urine passed by the wound, and in the course of a very short time he went out of the hospital completely cured.

Case 2.—J. G., aged 35, a coal heaver, was admitted October 17th, 1851, into Abraham Ward, with symptoms of extravasation of urine, respecting which the following history was obtained:—He had laboured under stricture for seven years past, but no retention had occurred until about nine weeks previously, when suddenly finding he was unable to pass any urine, he applied at the hospital and was admitted. On the nature of the case being made known, an attempt was made to pass a catheter, which, however, failed. A dose of opium was then given him, and he was sent to bed, which had the effect of relieving the retention, and procuring a flow of urine. He went out again, and four days previous to his re-admission noticed the swelling in the perineum. For long the stricture has been extremely tight, admitting the escape of only a very narrow stream, and his habits being intemperate, had doubtless fostered a tendency to spasmodic stricture. At noon Mr. Simon saw him, and performed the operation without any delay. To relieve the accumulated pus and urine, an opening had to be made into a collection of matter situated posterior to the scrotum, and another into the cellular tissue on the pubes: the latter yielded little result, but the former was followed by the escape of a quantity of pus. He was then ordered a pint of porter. On the day after, it was found that he had slept well, and that his appetite was good, but the pulse was rather full and quick, and he had several violent fits of shivering, which, however, disappeared by the next day. His appetite remained good, but as in the other case, the bowels were constipated, and had to be relieved by appropriate remedies. He now began to mend steadily, and though he complained of being weak and low, his pulse and appetite remained good, his urine improved in colour, the discharge of pus diminished, and the swelling subsided. On the 23rd of October, the catheter was changed, as it was much coated with the urinary salts; and on the 29th it was removed altogether, and one passed into the bladder by the penis. By this time the pulse and strength had steadily improved, his tongue had grown clean, his bowels were regularly open, and the urine was of average character. On the 1st of November the dilatation by bougies was begun, and continued regularly up to the date of Mr. Tyrrell's last communication to me on the subject (November 21st), when the man was just cured and about to leave the hospital.—*Med. Gaz.*

Accidental and Complete Evulsion of the Globe of the Eye.—Dr. Verhaeghe mentions the following case in the *Annales d'Oculistique*:—A fisherman of Ostend, returning home in a state of complete inebriety, fell against the key of his door. The ring of this key had become sharp by long usage, and cut the upper lid clean through from above downwards. Entering afterwards the orbit, it acted like a scoop, separated the eye from all the parts which attach it to its orbitar situation, and regularly extirpated it, so that the organ went rolling on the floor. Strange to relate, the man was so intoxicated that he did not heed this frightful wound, and went to bed. His wife, on rising the next morning, was much surprised to find that her husband had lost so much blood, and horrified at seeing the eye on the floor. The man was taken to the hospital, where the parts (a few shreds of conjunctiva, and of the recti muscles) soon cicatrized and adhered completely.—*Lancet.*

REVIEWS AND NOTICES OF BOOKS.

THE LAWS OF HEALTH IN RELATION TO MIND AND BODY; a Series of Letters from an Old Practitioner to a Patient. By Lionel J. Beale, M.R.C.S. London. 1851. Fcap. 8vo. pp. 306.

"Although there are many works on health addressed to the public, yet it cannot be said (Mr. Beale observes) that their influence has been sufficient to supersede the necessity of another while such manifold evidence continues of the desolations which afflict mankind from ignorance of the laws of health. The daily duties of a medical practitioner bring to his notice many lamentable cases, where a small degree of such knowledge would have prevented serious evils."

The author commences with some general observations upon the advantages to all classes of an acquaintance with the laws of health; which is followed by a brief sketch of the history of medicine, and some remarks upon empiricism, including homœopathy and mesmerism. "Among the diseases to which the human frame is liable, of course many (Mr. Beale observes) are incurable; and it is on the fears of persons thus afflicted that the inventors of novel modes of treatment, the proprietors of nostrums, and pretenders of all sorts, make their harvest."

"That the infinitesimal doses have no influence whatever on the animal organism, either in a morbid or healthy condition, is a fact which can be readily proved by experiment, if it be considered necessary to appeal to an experimental inquiry in order to prove that the millionth of a grain of charcoal, or the decillionth of a grain of opium, administered a certain number of times in the day, are utterly incapable of producing any marked effect on the functions of the animal body.

Homœopathy is a sort of revival of ancient medical practice, and is an attempt to go back two or three centuries—in this respect bearing some resemblance to other modern attempts to restore the mediæval absurdities of bygone ages. If life has ever been preserved by medical aid, then must homœopathy be one of the greatest delusions which human blindness ever adopted."

The next chapters embrace a popular account of the organs and functions of digestion and respiration; of the skin and brain. The brain is then considered in relation to the faculties of the mind, the instincts, ideas, &c.; and the subject is followed up in succeeding letters under the heads "progress of the mind in childhood," "faculties latent at birth, gradually developed by education," "development of the observing and perceptive faculties," "progress of the mind from childhood to maturity."

"Having traced the general processes of the animal economy and the various influences of systems and organs in their relations to each other in health and disease," Mr. Beale proceeds to show "the operation of the laws of health at various periods of life." Commencing with the laws of health in infancy and the disorders of childhood, the author considers in succession "the maturity of mind and body," "the effects of dissipation and mental excitement," at this period; and the diseases incident to the meridian of life.

The 22nd chapter is devoted to the health of mind and body at the age of 50:—

"The beginning of the second half century of human life is an epoch at which many changes of constitution have become very apparent. The hair is thinner and grayer; the eyes require the aid of spectacles; muscular power has declined; we are no longer capable of enduring so much exertion, and other symptoms of declining years may have become perceptible. Very active exercise is not so necessary to health as in earlier life; our regard for ease limits our exertions, and this with an increase of the pleasures of the table, induces a disposition to obesity, with its common attendant, disturbance of the balance of the circulation. We should at this age carefully attend to any symptoms about the head, such as giddiness, noise in the ears, frequent headaches, specks before the eyes, &c., which indicate mischief that may, after a time, terminate in apoplexy and para-

lysis, unless the full tide of nourishment is arrested. Congestion or inflammation in other important organs, the lungs, the liver, or the kidneys, may be induced by similar causes.

Indolence of mind and body, and indulgence in the pleasures of appetite, are the foundation of innumerable ills, which reach their acme after the age of 60, and either carry off their victims about the period styled the grand climacteric, or establish some of the disorders which render old age unenjoyable. The true remedies for this state of things are temperance and exercise; but there are few who, for the sake of health, can be induced to relinquish the pleasures of eating and drinking, which generally destroy the capability as well as the desire for exercise. We can only depend on secondary means of preventing congestions and disturbances in the vital organs by purgatives, and occasional abstinences from the usual heavy feeding. If the warning of increasing corpulence, and some of the above-mentioned symptoms, is not attended to, and a more moderate style of living adopted, apoplexy, heart-disease, dropsy, &c., may cut short the thread of life, or render the victim a helpless invalid."

The remaining chapters are devoted to the "laws of health to be observed in advanced life, and the disorders of old age: and the volume concludes with a general summary of the laws of health with reference to mind and body, from which we extract the following passages, with which we shall also conclude:—

"The principal laws of health, the regulation of which are under our own control and power, relate to the organs of digestion and respiration, the skin and the brain.

1. Temperance and sobriety in eating and drinking, taking only those things which we know to agree with us, and in moderate quantity.

2. To breathe as pure an atmosphere as possible, by living in well-ventilated houses and apartments, by exercise in the open air for several hours daily, in order that the whole of the air cells may be emptied, and a fresh wholesome change of the particles of air may reach every part of the lungs.

3. To maintain a free state of all the pores of the skin by ablution and friction, so that there shall be no obstruction to transpiration: once at least in every twenty-four hours we should increase the ordinary transpiration to perspiration by active exercise.

4. To promote the healthy action of the brain and nerves by active mental employment, giving to the mind, by proper exercise of all our faculties, mental and moral power to keep in subordination the emotions, the passions, and the propensities."

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JANUARY 7, 1852.

THE PRESENT POLICY OF OUR PROFESSION.

With the New Year commences a new era for medical affairs in Ireland. Not only does the operation of the new Dispensary Act throughout the provinces effect a revolution, but in the metropolis circumstances for some years in operation seem to have caused a similar commotion. A storm has arisen, and it remains to be seen whether the Surgeons of Ireland can weather it as they have other storms within the last half century; or whether, distracted by a multiplicity of difficulties, and weakened by division, they are to fall a sacrifice to the elements which threaten them. Of their power and ability to surmount any such difficulties we ourselves entertain no doubt, provided always that they prove true to themselves by a resolute determination to adopt the word UNION as their rallying guide, and that they never lose sight of a few principles of action which can scarcely be questioned. We are not so sanguine or so inexperienced as to suppose that incomplete unanimity can be secured amongst us as to matters of detail, or that all can be relied upon to adhere steadily to any rule of conduct, however beneficial to all; but we are sanguine enough to believe that a very large majority of our body can act in concert for the attainment of paramount objects. There are certain points respecting which all must agree, with the exception of those who recognize no obligation, and who look not beyond the present moment. No one will deny that the labourer is worthy of his hire, and that in accordance with that maxim the Surgeon should, like every other man, be honestly paid for his services; yet several may be found willing to give practical proof of their readiness to depart from a rule founded on such an assumption. Many will say a £100 a year is very inadequate payment for their services, but if they cannot obtain that will accept £50. With such men let us not quarrel, neither let us in disgust abandon our principle, for these men are still of our opinion, although compelled by hard necessity to act contrary to it. Allowances must be made for exceptions, for otherwise *union* cannot be secured, and without union success cannot be achieved. All must be prepared on all occasions to assert the rights of Surgeons to adequate remuneration for their services, and on the present occasion all should be prepared to advocate the grant of some specified sum as the Dispensary Surgeon's salary. We have, we confess, been cautious in the expression of our opinion as to what that sum should be pending the formation of districts, but that being now to a certain extent agreed upon, we, after mature deliberation, come to the conclusion, that a £100 a year may be named as the sum fairly to be expected. This we state by way of example of a practical application of a fixed principle, and we would therefore have it set down as number one of several items equally important which we would suggest for adoption. The point next in importance at the present critical moment requiring united action is that of protection against imposition. Upon the course the Dispensary Surgeons now pursue with respect to the tax on their professional services, hitherto levied for the easement of persons of limited means, not being "poor persons" or "fit objects for dispensary relief," much will depend hereafter. If they now submit to the perpetuation of this tax by a perversion of the law, they will have themselves only to blame. We counsel not any ungenerous or unfeeling denial of that relief which the Surgeons of Ireland have at all times afforded, not merely to the labouring poor, but to the others in narrow circumstances not willing to be considered poor; we only advise a firm resistance to all attempts to compel them to afford gratuitous relief to persons of adequate means. Another point which claims the attention of all, is the extent of district upon which the Surgeon should be called to undertake the attendance; not merely to prevent the approval by the Commissioners of the excessive districts formed in some of the unions, but to prevent hereafter the union of districts; or perhaps the farming out of the whole union to one man. Every one knows that men might be found willing to undertake the care of two or three districts if paid the amount of two or three salaries, although the proper attendance on such might be physically impossible, but such a proceeding, however advantageous to the ratepayers, would be a mere evasion of the act. If some Surgeons be found discharging excessive and slavish duties, the Guardians will presently require others to do the same. In Abbeyleix Union, the resolution of a former board has been rescinded, and the number of districts reduced, the

argument used being that one of the present Surgeons had performed larger duties than those now required. Many other points will require the active interference of Surgeons whenever they resolve to act in cöoperation, and amongst them not one will more imperatively demand their attention than the lowering of the standard of surgical qualification. Of this we have over and over again warned them from time to time, and now we repeat the warning. If our profession becomes crowded throughout the country by the intrusion of persons into it who have obtained the usual qualifications by illicit means, or who hold spurious certificates of fitness furnished to them by unauthorized parties, regular practitioners will be undermined, and facilities will be afforded for providing that cheap system of medical relief which certain ratepayers so earnestly advocate. From the above observations our readers will gather that we are anxious to remind our brethren throughout the provinces that the period has arrived for that exercise of unity of purpose and action which is essential for their safety. A hint only we hope is necessary to convince them that whatever other securities may exist for their protection, they should not fail to preserve and improve that which in time of need is most to be relied on, their own exertions concentrated and regulated by union and cöoperation.

APPEAL TO A BOARD OF GUARDIANS.

We solicit particular attention to the following document, it being the first attempt to induce a Board of Guardians to reconsider its decision. At first sight, such a course seems an obvious one, but much must depend upon the temper and composition of the board upon which such an experiment can be tried. Here it seems not to have been very successful, and one of the board could not refrain from the expression of splenetic feeling respecting it. An attempt, however to rescind the resolution forming the districts, with a view to their diminution in number, was defeated:—

Memorial to the Board of Guardians of Mountmelick Union.

The undersigned medical attendants of the existing dispensaries of the district, respectfully showeth—

That memorialists have observed, by reports of the proceedings of your board, as published in the newspapers, that you have divided the union into dispensary districts, and named salaries which you approve of as proper compensation for the medical officers.

That though your memorialists have formed opinions on the subject of the districts, and are not prepared to state that such districts appear to them to have been judiciously arranged, your memorialists feel, as that particular subject is at present under consideration, it would be premature for them to enter into details respecting it.

Your memorialists would deem it false delicacy, should they abstain from declaring that the proceedings of the board have imposed on memorialists an obligation to urge, in self-defence, that the salaries named by the board are wholly insufficient as remuneration for the services to be performed, and are inequitable as regards memorialists, whether the matter be viewed in relation to past rate of salary, future amount of duty and responsibility, or to the extent, value, and population of the districts.

Memorialists are aware that a power may exist to force on them, within certain limits, terms which they cannot feel to be just towards them; they, however, most respectfully press upon the whole body of the guardians, the propriety of weighing, as honest men, the true value of services in no respect inferior, in importance to society, to those performed by any, even the very highest officers of the state.

Were your memorialists to approach the naming of a fair annual sum to be paid, as an average salary in dispensary districts generally, they could not possibly approve of a lesser sum than £100 per year, rendered in some instances larger, according to special circumstances, in particular districts.

Relying on a spirit of justice in your board, memorialists feel that it would ill-become them to doubt that their opinions shall receive due attention from you. They do not apprehend that they shall have to seek protection in any other quarter than from you, whose experience and knowledge of what is just by the sick poor and their physicians, should enable you to adopt arrangements likely to prove satisfactory to all.

A. E. Tabuteau, M.D., Surgeon to Portarlington Dispensary, Chairman; M. W. Fisher, M.D., Surgeon to Ballybrittas Dispensary; H. J. Smith, L.R.C.S.I., Surgeon to Mountrath Dispensary; J. R. Clarke, M.D., L.R.C.S.I., Surgeon to Emo Dispensary; William Thornell, M.D., F.R.C.S.I., Surgeon to Mountmelick Dispensary.

My opinion having been requested on the subject of the above memorial, I have to express my full concurrence in all the sentiments therein contained.

John Jacob, M.D., &c.,
Surgeon to the Queen's County Infirmary.

CORRESPONDENCE.

"THE DISPENSING OF MEDICINES BY SURGEONS TO THEIR OWN PATIENTS."

". . . . . Having, in common with my professional brethren, the utmost reliance on your able and honest advocacy of the rights and privileges of our profession, I beg respectfully to call your attention to this subject," &c. &c.—*A Dispensary Surgeon in* Medical Press *of November* 26, 1851.

"Our correspondent may rely on our inclination to deal with this matter, and we are convinced of the inclination of the college to do the same."—*Editor's remarks on the above in* Medical Press *of November* 26, 1851.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I hail with unalloyed pleasure the prospect held out in the foregoing remarks "of making the College of Surgeons *in* Dublin, even now *the* College of Surgeons *of Ireland*, and rendering it the bond of union between the several classes of the profession in this country;" thereby carrying out to the fullest extent the original object of the Charter of 1844, by opening its doors "for the reception of practitioners in surgery of long standing, and possessed of irreproachable moral and professional character." For liberal and unprejudiced though the admissions to the fellowship were in that year, many, very many, who would be otherwise delighted to avail themselves then of the privileges of the charter, were reluctantly compelled to forego that honour in consequence of their being totally unable (from peculiar circumstances, or rather from being peculiarly circumstanced) to abide by the conditions, laid down by the council in reference to the above heading.

The writer of this, a former pupil of the college, and long a member of the Medical Association of Ireland—the rules of which prohibited its members from "being engaged in the business of retailing drugs or compounding the prescriptions of others"—was nevertheless debarred from the fellowship because he was necessarily compelled "to dispense medicine to his own patients," owing to his being located in a district, parts of which were fifteen and twenty miles distant from any apothecary or druggist; so that to save time and trouble, he is actually obliged to carry a medicine-chest in his vehicle when called to see a patient. Surely the stringency of the rule which deprives men so circumstanced of the fellowship of the College of Surgeons of Ireland, should be a fit subject for consideration by the council, with the view to its modification, to suit the wants and wishes of the many who are at present suffering under it.

Although your remarks have reference chiefly (and perhaps only) to existing fellows, yet I should hope that, if the council should make any modification of the rule complained of by "A Dispensary Surgeon," they will extend the rule to such at least as were excluded in 1844 for want of such a modification; and as it appears from your observations, that the council would not be indisposed to meet the wishes of the profession in this respect, might I respectfully suggest the adoption of the rule laid down by the Medical Association of Ireland on the same subject, to get over the only difficulty

that appears to me to exist in coming to a satisfactory settlement of this important subject.

Sincerely hoping that I will ere long hear of the successful issue of this case, I have the honour to remain your obedient servant, CHIRURGICUS.

It would not become us, in this place, to dictate to the College of Surgeons, by suggestion or otherwise, any line of conduct in reference to the point to which our correspondent alludes; but it is our legitimate duty to impress upon our brethren, at the present critical moment particularly, the importance of this matter. We cannot see how persons who hitherto relied on the dispensary for relief, but who are now excluded, can be treated, unless the Surgeon makes some provision for the supply of medicine to them. Where good apothecaries exist, and do not make themselves the rivals in practice of neighbouring surgeons, an arrangement can be made without much difficulty; but in the case to which our correspondent alludes, it is otherwise. As to Members of the College of Surgeons, the disability to dispense medicine applies to the Fellows only; Licentiates are at liberty to do so as fully as they please. It may be well to bear in mind now, when an assimilation of the practice in Ireland to that of England seems in this respect inevitable, that Surgeons who adopt it must take a more business-like view of the matter than they have hitherto done. They must make up their minds as to the course they should pursue to enable them to live. If a gentleman calls himself Doctor and Physician, accepting his fee as an *honorarium*, and writing his prescriptions, he must be satisfied with the consequences; he cannot recover payment for his attendance even as a Surgeon. But if he calls himself Surgeon, charges moderate fees, and dispenses or not as convenience may require, he becomes what in England is called a General Practitioner. How far the comfort and affluence enjoyed by this class in England may tempt our Irish brethren to follow their example, however, remains to be proved.

HINTS ON THE DISPENSARY ACT.

WE solicit the attention of our readers to this letter. Much of it corroborates our views, and more of it saves us the trouble of urging the points touched upon:—

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—I believe that the avowed object of the Medical Charities' Bill is to afford efficient medical relief to the poor throughout Ireland. That it was the intention of the legislature that such relief should be afforded in a *bona fide* manner, there can be no doubt; yet when we take a review of the proceedings of the various boards of guardians for the last month or so, in dividing the unions into districts and fixing the salaries of the medical officers, it would appear that the majority of those gentlemen seem to consider the interests of the poor in a secondary point of view; whilst imposing hard labour on their medical officers, with large districts and paltry salaries, is ranked as a matter of the first importance. In fact, in most instances, they have appeared only to vie with one another in proposing the lowest salary for the greatest quantity of work, and heaping unmerited degradation on our profession. In very few instances have they allowed anything like fair remuneration for the duties required to be performed; whilst, in most cases, the districts are of such magnitude, comprising an area of eight, ten, or twelve square miles, that it would be morally impossible for one man with the fleetest horse—leaving his private practice out of the question—to discharge his duties conscientiously with benefit to the poor. Yet this is to be the substitute for our old dispensary system; which, with its many acknowledged evils, had at least one recommendation—that it proved a blessing to the suffering poor. That this new bill may become a blessing or a curse to the land, will depend in a great measure upon the exercise of that discretionary power placed by the act in the hands of the Poor-law Commissioners. If they require that the poor be properly attended to in the hour of sickness, they ought also to insist that fair remuneration be given to the medical officers, in whose charge they place so great a responsibility. On the contrary, if they allow the dispensary surgeons to be oppressed with over-work and scanty remuneration, what other than the most disastrous consequences must follow—alike ruinous to the poor and degrading to the profession. I say, then, in order that this bill may become practically useful in this country, properly qualified officers must be appointed, and a fair remuneration given for their services. Such fair dealing with the medical profession would, in the end, prove a source of economy to the ratepayers. It is more than probable that most of the guardians, in fixing the salaries for their medical officers, were at the time quite ignorant of the duties which will be required of them. Were they aware, when they were fixing those salaries, that the duties are most laborious and harassing; that their medical officers will have to attend to all applications for visits, when a ticket is presented either from a member of the local committee or from the relieving officer. In midwifery cases, also, he will be obliged to give his services, for the act draws no distinction of cases. He will have to attend patients in natural as well as dangerous labour; and it may be taken for granted when the poor people know that they have a right to call on the doctor in such cases, they will not be slow to avail themselves of an advantage which many in the middle ranks of life are unable to procure. The medical officer is also expected to vaccinate all children which may be brought to him for that purpose. He will have to attend at the examination of dangerous lunatics, and give attendance at bridewells within his district. He will also have to assist the commissioners in the removal of nuisances, and obey the orders of the commissioners in many ways too tedious to mention. Thus it is evident that the time of the medical officer, which will be so fully occupied with his ordinary duties, must also be devoted to midwifery cases, and a host of other employments, when any of these extraordinary cases occur. He will become bewildered amid the mass of business, and leave the half undone. Let us suppose a case. The doctor is summoned early in the morning to attend a woman in her confinement, living five or six miles from his residence; he goes there, and finds her in tedious labour—all safe, nevertheless; the patient and friends are anxious that he should remain in the house; he, feeling his responsibility, is unwilling to leave her, and remains till the delivery is completed. He returns home after eight or nine hours' delay, wearied no doubt, and finds a number of applicants waiting in the dispensary for relief; others from all quarters of his district with visiting-tickets from committee men, all urgent for domiciliary attendance. What is the doctor to do under these circumstances? He cannot possibly attend to all: he must leave them to their fate till the following day. Although some may think this to be an exaggerated case, I am of opinion that it will be one of ordinary occurrence, unless the Poor-law Commissioners stand forward and meet the difficulties which present themselves.

It has been said lately by one of the Medical Inspectors under the poor-law, at a meeting of a board of guardians held in the north of Ireland, that the salaries already settled upon were higher in proportion than those given to the parochial surgeons in England. In this, I think, he was mistaken; as he seemed to forget that relief is given in England to the destitute poor alone, whilst in Ireland it will be given—as the act states—to the poor: destitution not being a necessary qualification. Besides, the doctors in England are allowed 10s. for each midwifery case, which, in the end of the year, makes a vast addition to their annual income.

Knowing, then, the extent of our grievances, we should take into consideration the best mode of redressing them. This should be done by calm but firm representation. We should not on any account offer any factious opposition to either the Poor-law Commissioners or Poor-law Guardians. We should rather assist these boards with any suggestions which our lengthened experience of dispensary practice may dictate; and I am sure that our Medical Commissioner—a gentleman of honour and integrity, and in whom the profession may justly place every confidence—will not be indifferent to the voice of the profession. We must not, however, depend either on boards or individuals. If we wish to have our grievances redressed, we must stand firm together, and put our own shoulders to the wheel.

The poor-law guardians have already shown us how they can discharge their duties: we now wait in extreme anxiety

to see how the commissioners will fulfil theirs. We do not think that the commissioners can, in common justice to the medical profession, sanction the late proceedings of the poor-law guardians. The commissioners have also an equally important task to perform: they have to frame general rules and regulations for the government of each dispensary district, and for the guidance and control of the guardians, the committees of management, and the several officers to be appointed in connexion therewith respectively. The harmonious working of the bill will, in a great measure, depend upon the judicious framing of these rules. In these rules, instructions should be given to the local committees stating the class of patients which are eligible for dispensary relief; this can be easily done in general terms, and will prevent eternal disputings amongst the local committees. Strict rules ought also to be enforced to bring the poor into regular habits. An order ought to be issued that the gentlemen comprising the various committees will not give tickets—except in cases of great urgency or accident—after ten o'clock in the morning, and that such tickets must be left at the dispensary before eleven o'clock a.m. of the same day. Unless a rule of this kind is enforced, there is no medical officer who could get through his business with any satisfaction either to himself or the poor.

The local committees will also have their duties to perform as soon as they are elected; they ought, one and all, to represent to the commissioners and poor-law guardians, the utter impossibility of their medical officers attending to all ordinary cases of midwifery. They should, therefore, recommend to the commissioners the importance of having a qualified midwife appointed in each dispensary district, to be paid a certain sum per case; such a person could attend to all ordinary cases of childbirth without the assistance of a doctor. Should any danger arise, in the progress of any case, it will be her duty to have the doctor summoned.

If proper rules of this nature are not made and enforced, it is impossible that the bill can work well; if, also, the honour and dignity of the medical profession is not upheld, it will be found in time that no man of education will accept of a dispensary under such hard taskmasters. The poor must, consequently, be the chief sufferers. Their diseases will be mistaken and maltreated; death will increase, and contagion will spread from the poor man's cabin to the rich man's palace; thus this bill, which by a little liberality might be made a blessing, may, through injudicious regulations and short-sighted economy, become the bane of the land.

I know that the ratepayers will say—We see that the doctors are dissatisfied, but we care not; we will always be able to get doctors, good enough for the poor, at the salaries we propose. Let them, however, beware that the biter be not bitten. Although the present race of medical officers attached to dispensaries—than whom a more enlightened or better educated class of practitioners does not exist in the whole world—may, through dire necessity, accept office under this new act, yet in time a class of half-educated men—made for the market—will rise up to fill these situations. The ratepayers may still think them good enough for the poor; they will, however, have no other alternative but to employ them when sickness comes to their own doors.

The medical officers of dispensaries should meet together without loss of time to take into consideration the dangers and difficulties of their position. Sufficient has been said to show that the successful working of this measure must depend on the zealous coöperation of all parties: if one single part of this superstructure is badly put together, if it cannot be made into one harmonious whole, the entire fabric will totter, and become a chaos of endless confusion.—I am, sir, your obedient servant, A SUBSCRIBER.

THE QUESTION OF PLURALITIES.

We promote the object aimed at by the writer of the following letter sufficiently by giving insertion to it, without expressing any opinion other than we have already expressed on the subject. Where conflicting interests embarrass a question, we must refrain from comment until they cease to affect it:—

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—I am desirous of calling your attention to a matter likely to be of frequent occurrence under the new medical act in the several unions throughout Ireland, in relation to the formation of dispensary districts and the appointments of medical men thereto. In some instances where it happens that in the same union there have been two separate dispensaries attended by two distinct medical men under the old system, one of them, in addition to his dispensary, has also the attendance of a workhouse, for which he receives a salary. Now, by the operation of the late act, in the division of the union into districts by the board of guardians, the two dispensaries referred to are put into one, or joined together, so as to form a district under the now existing law. I wish to know is it consistent with the spirit of the act, that the medical attendant to the workhouse, who generally has one thousand inmates to attend, and seldom less than one hundred in hospital and infirmary, should claim to be preferred to the other medical man, who is not encumbered with official duty, and who has attended one of the dispensaries mentioned above in the locality for many years, and is well established and regularly qualified? As to me, it appears that the intention of the act was and is, to provide for as many of the original dispensary attendants as arrangements under it would permit, and not for the purpose of conferring "pluralities," by the exclusion of those who have a just claim, as also to afford necessary medical aid on a scale sufficiently extensive for the relief of the destitute poor, and not to create an injustice by sanctioning the appointment of any man that has not it in his power, from preëngaged official duty, to attend to the poor efficiently.

I sincerely hope, that as the guardian of "equal rights" of the profession, you will please have this matter brought under the consideration of the commissioners, so that justice shall be meted out to all parties, and that the man rendered plethoric with "full rations," may not be allowed to purloin the "cup of thin gruel" from a fellow-labourer equally meritorius. By giving insertion to this in your highly estimable PRESS, you will oblige one of your earliest and constant subscribers.—I am, sir, sincerely yours, JUSTITIA.

NAVY MEDICAL SERVICE.

We cheerfully give insertion to the following observations on this subject, and at the same time venture to express a hope that, at this critical moment, everything that can be done to render this department efficient, and to secure its harmonious operation, will be done. We at the same time also have to express a hope, that no importunities will avail to lower the surgical qualification for the situation of Navy Surgeon, or to substitute any sham or spurious diploma for the regular surgical one of the Colleges of Surgeons usually required:—

TYRANNICAL CONDUCT OF ADMIRAL SIR WM. PARKER.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—The following unwarrantable conduct on the part of the Commander-in-Chief on the Mediterranean station is reported in the *Morning Herald* of the 23rd of December, 1851, wherein the two-faced conduct of the Admiralty is seen through:—

"Some days ago, after the return of the Queen from her cruise, Mr. Stirling, a supernumerary acting-lieutenant, applied to the captain to have the use of one of the cabins on the main deck, vacated by one of the admiral's domestics. On the request being referred to the admiral, he made inquiries as to who occupied the cockpit cabins; and on finding that one of them was occupied by Mr. D. J. Duigan, assistant-surgeon, an officer who is part complement of the Queen, he ordered him to be displaced immediately and the cabin given to the supernumerary acting-lieutenant (Mr. Stirling). Mr. Duigan, obedient to orders, vacated the cabin, which he had been in possession of for nearly eight months, and at the same time appealed to his captain by letter, in the most respectful manner; and pointing out the Admiralty Circular of the 17th July, 1850, granting assistant-surgeons cabins, and the Queen's Regulations (art. 6, p. 7), which directs that supernumeraries shall not be permitted to displace any of the established officers of the ship in their accommodations on board.

The Commander-in-Chief says that Mr. Stirling is not a supernumerary, but an additional lieutenant.

In another instance, Mr. Pearce, being then at home, and in ill-health, on leave, was appointed to the Modeste. The appointment was declined until a promise had been given that he should have his cabin when Mr. Pearce joined. The

gentleman had fitted up his cabin with comfort; had brought several botanical and other specimens useful to his profession, and instruments and drawings necessary; things, in fine, he would never have brought to sea but for the promise of his cabin. Of this he has been deprived, in spite of the solemn promise made to him at home. These really seem to us to be very harsh proceedings, and we hope will form additional items to the long list of grievances which, on the assembling of parliament, will be brought forward when the humiliating position of naval assistant-surgeons shall be before the house. We have since learned that Mr. Duigan has been offered his cabin, as Lieutenant Stirling is only on board for a passage to the Growler, but on condition that in the event of an additional, *alias* a supernumerary lieutenant being appointed, he will have to give it up. The offer was, on these conditions, firmly yet respectfully declined; Mr. Duigan not judging it necessary to accept as a boon what he considered should be his as a right. However wedded may be Sir William Parker to old theories and older habits, it would be but an act of duty to consult the interests of the service by giving to the assistant-surgeon the position granted him by order of the Board of Admiralty; in other words, to obey those orders from his superiors, which no one is more particular than he in exacting from those under his command."

Mr. Duigan is, I believe, a Fellow of the Royal College of Surgeons of Ireland. Such is the treatment of a naval medical officer, that it is to be hoped the national medical colleges will enter a crusade against the Admiralty to stop medical men from joining the navy.—I am, sir, yours,

AN ASSISTANT-SURGEON, R.N., M.R.C.S.L., L.A.C.L.

THE MEDICAL OFFICERS AND ADMIRAL SIR WILLIAM PARKER.

THE Mediterranean of all naval stations, labours but too successfully in maintaining its not very enviable pre-eminence in opposing the rights of the assistant-surgeons of the navy. So far back as the month of May last, Captain Boldero, in his place in the House of Commons, stated, that the order of July, 1850, regarding cabin and other accommodation to assistant-surgeons, was in but too many instances a "dead letter," and particularly mentioned the Mediterranean as the station on which that order had been treated with almost systematic evasion. From a recent Malta *United Service Journal*, and from some other sources, we learn that two assistant-surgeons have lately suffered cabin "ejectment," and under circumstances which clearly show that so long as the present Commander-in-Chief has the power, there will be no want of the will to render the position of assistant-surgeons as humiliating as possible. It would appear that on board her Majesty's ship Queen, the flag ship on the Mediterranean station, of the three assistant-surgeons who possess ward-room rank, one only has been provided with a cabin. This he seems to have occupied in the cockpit without molestation until some time in the latter part of November last, when he was ordered to vacate his quarters in favour of Mr. Stirling, a supernumerary acting-lieutenant who had for some time held a cabin on the main deck, usually occupied by a servant maid, when embarked. We are not informed whether the unexpected arrival of the maid on board gave rise to this rather unceremonious ejection of the assistant-surgeon from the cockpit cabin and its occupancy by the lieutenant; but the assistant-surgeon, relying upon the Admiralty order of July 17, 1850, which provides that assistant-surgeons shall have cabins when the accommodation on board will admit, and trusting to the "Queen's Regulations" (chap. ii. part 6), which enjoin that "supernumerary officers shall not be permitted to displace any of the established officers of the ship in their accommodation on board"—reverting also to a most *apropos* case in point, in which the same supernumerary acting-lieutenant had, on a former occasion, been ordered by the captain to vacate his cabin for a lieutenant of marines, while he (the assistant-surgeon) was left in possession—considered it a duty he, on the occasion in question, owed his brother officers as well as himself to make a respectful but firm remonstrance to his commanding officer. The result of this appeal seems to have been nothing more than something very closely allied to disingenuous quibbling on the part of the admiral, for, from the Malta *United Service Journal*, we learn that "the Commander-in-Chief says that Mr. Stirling is not a *supernumerary* but an *additional* lieutenant. Strange

"That such difference should be
'Twixt tweedle-dumb and tweedle-dee."

With all deference to the Commander-in-Chief, we will venture to inform him that to endeavour to institute a difference between the words *additional* and *supernumerary*, as regards officers, is simply an absurdity. In the first place, we doubt if the word additional, as applied to an officer, occurs in the printed instructions. It is not to be found in the printed sheets in which the complements of officers, &c., of ships are given. When *additional* officers are borne on a ship's books, they are included under the head of supernumeraries for wages and victuals, and returned accordingly. We trust, then, that in any future essay at the expulsion of an officer from his proper cabin, the Commander-in-Chief will discover some reason for such a course, more consistent with the dignity of his position, and less at variance with common sense, than a mere arbitrary distinction between two words which, as every one else knows, possess essentially the same meaning. But after all, the quarters of the servant maid were not destined to remain altogether uninvaded, for in a very short time after the supernumerary (or, according to the admiral) the *additional* acting-lieutenant had taken possession of the assistant-surgeon's cabin in the cockpit, he was appointed to her Majesty's ship Growler, at this time on the eastern limits of the station, and thereby became a passenger awaiting to join his ship. He was then ordered from the cabin in the cockpit to resume his occupancy of the servant maid's cabin on the main deck, and now the assistant-surgeon was offered repossession of the cockpit cabin, on the condition that he would resign it in the event of another supernumerary or additional lieutenant joining the ship. The assistant-surgeon properly, as we think, declined the tenure of the cabin on such humiliating terms, and there, so far as we know, the question at present rests. There is another case on the same station, which is remarkable for possessing some features of peculiar and unwonted hardship. As we shall reserve its discussion for a future occasion, we are, therefore, unwilling in any degree to prejudge it. This is the less necessary as we understand that both cases will undergo proper and searching investigation. But as it has been rumoured that, in this second case, threats were used to the assistant-surgeon, when deprived of his cabin, to deter him from making that appeal which is the right of every British subject, whether in the service or out of the service, we trust, for the reputation of the English navy, for the sake of our common nature, that the report has orignated in error. Should it, on the other hand, prove to be but too correct, then we would only observe that, the man who, in the present day, dares to stifle respectful remonstrance against an act supposed to partake of injustice or oppression, altogether mistakes the requirements of the age, and commits an outrage upon its intelligence.—*United Service Journal.*

ADDRESS TO JOHN MACDONNELL, ESQ., M.D.,

MEDICAL POOR-LAW COMMISSIONER FOR IRELAND.

SIR,—We, the medical practitioners attached to dispensaries within the Cork union, beg leave to offer you our very warm and sincere congratulations at your appointment, as Medical Commissioner, under the Medical Charities' Bill.

When we consider the lively interest you have long taken in the honour and dignity of the medical profession, and the very high character you bear as a professional and educated gentleman, we feel deeply grateful to government for its wisdom in selecting you to fill a responsible situation, in discharge of which we feel well assured you will consult the interests of the sick poor, while you protect those of the ratepayers, as well as uphold the welfare and respectability of your medical brethren.

Trusting that you may long be spared to assist by your sound advice the non-medical commissioners in carrying into salutary operation this important bill,—We have the honour to remain, sir, with great respect, your very faithful servants,

Henry O'Brien, M.D., Chairman; C. Y. Haines, M.D.; R. T. Fowler, M.D., M.R.C.S.Eng.; Thomas Gregg, M.D., L.R.C.S.I.; George A. Rountree, M.D., M.R.C.S.Eng.; Thomas Wall, M.D., M.R.C.S.Eng.; Robert D. Parker, M.D., L.R.C.S.I.; Philip R. Twigg, M.D., M.R.C.S.; W.R. Lane, M.B., T.C.D.; N. J. Hobart, M.D.; Wm. Henry Sandham, Surgeon: P. J. Barry, M.D.; B. Johnson, M.D., A.B., &c.; Charles Armstrong, M.D., F.R.C.S.I., Secretary.

Cork, December 15, 1851.

REPLY.

4, Gardiner's-row, Dublin, December 10, 1851.

GENTLEMEN,—I beg leave to return you my warm and cordial thanks for your kind congratulations on my appointment as Medical Commissioner under the Medical Charities' Act. Believe me, in the performance of the duties that have devolved on me, it is my earnest and anxious wish, to the best of my ability and judgment, to consult, as you so kindly anticipate that I will, the interests of the sick poor and of the ratepayers, and to uphold the welfare and respectability of my professional brethren. I am well persuaded, that the latter cannot be sacrificed without serious detriment to the real interests of both the sick poor and the ratepayers.

Accept my sincere thanks for your good wishes, and believe me to be, gentlemen, your very faithful servant,

JOHN MACDONNELL, M.D.

To the Dispensary Physicians and Surgeons of the Cork Poor-law Union.

NEW VIEWS ON THE SUBJECT OF PYROMANIA.

MORE than twenty-five years ago, the Austrian Government, influenced by medical reports, admitted a then current theory respecting the cause of one class of crime, and modified the practice of the Criminal Court with regard to them. There had been several cases of arson *(Brandstiftung)* committed by very young persons, and medical men attributed it to a peculiar "organization" in the criminals, that drove them by an irresistible impulse to fire-raising: thrusting a lucifer into the dry thatch of a barn was, in fact, merely the symptom of a human malady, to which they gave the name of "Pyromania," or, in German, the more formidable title of "Brandstiftung-strieb." Yielding to this medical theory, the government ordered that in all such cases the criminals should be subjected to a professional examination to ascertain whether they were afflicted with this really dangerous, and, in its effect at least, most catching disease, or whether they were responsible for their act by the possession of so much of the shepherd's philosophy as taught him that "the property of fire is to burn." Since that period (1824) the medical profession has, on further investigation, itself condemned and renounced the theory, and determined that the plea of "irresistible impulse" and a peculiar "organization" against a charge of wilful fire-raising is not a sound one; the government, therefore, has also revoked the legal practice founded on the erroneous theory, but with its customary maturity of deliberation. A medical report, dated in October last, states that the medical profession has for many years been convinced that the doctrine in fashion a generation ago was a false one. The decree releasing the Criminal Court from the obligation of handing over all youthful incendiaries to the doctors is only of the 30th of November. In future, the court is to use its discretion, and order such an investigation only when there are grounds for it, as it does with other criminals. The eminent medical men who have signed the report on which the present decree is founded, request to be relieved from the duty of examining all persons charged with this crime, and pronouncing a decision on their responsibility, which only had the effect of delaying the prosecution, the doctrine on which they were authorized to act having long been exploded; they assert confidently, that the efficacy of the law will not thereby suffer the least injury.

IODINE RENDERED SOLUBLE BY SYRUP OF ORANGE-PEEL AND TANNIN.—M. Debauque mentions, in the *Journal de Pharmacie* of Antwerp, that he has found means of keeping iodine in a state of solution, when added to mixtures in the form of tincture. The author uses, for that purpose, syrup of orange-peel, which answers the purpose perfectly. It was suspected that *tannin* was mainly instrumental in this result; and this was rendered evident by putting a few grains of tannin into a quantity of water to which tincture of iodine had been added, and in which the iodine had of course been precipitated. The addition of the tannin caused the iodine to be immediately re-dissolved. Thus will the syrup of orange-peel be advantageously added to mixtures containing tincture of iodine, and tannin to injections composed of water and the same tincture.

THE ITCH CURED IN TWO HOURS.

DR. BAZIN, physician of the Hôpital Saint Louis of Paris, introduced not long ago a notable improvement in the treatment of the itch, since he succeeded in curing the disease in *two days* by general frictions with the sulphur ointment. Dr. Hardy who has succeeded Dr. Bazin in the Scabies wards of the same hospital, has, however, considerably curtailed this already short time; he cures his patients in *two hours*. The method is described as follows:—Patients are no longer admitted *into* the house for the treatment of the itch, as two hours suffice to render contagion impossible and the recovery almost certain. The patient is put into a warm bath, and rubbed for an hour with yellow soap; he then passes into a clean bath, where he continues to cleanse his skin for another hour. After leaving this bath he is taken to a particular room fitted for the purpose, and, with the aid of one of his fellow-sufferers, he is rubbed all over for half an hour with the following ointment:—Axunge eight parts, flowers of sulphur two parts, carbonate of potash one part. After this friction, the patient is examined and sent away cured, though sometimes pretty numerous vesicles on the hands and elsewhere remained unalter. Dr. Hardy states that out of one hundred cases he has hardly had two or three relapses. The number of itch patients has considerably diminished, as none are now turned away for want of room; and the disease has thus spread with much less rapidity.—*Lancet*.

SKIBBEREEN DISPENSARY.

AT a General Meeting of the Subscribers, held by requisition, at the Dispensary, on November 25, 1851,

DANIEL MCCARTHY, Esq., in the chair,

It was proposed by Thomas H. Marmion, Esq, seconded by Daniel Welply, Esq., and resolved unanimously:—

That we, the subscribers of the Skibbereen Dispensary, are desirous of expressing, in the strongest manner, our high estimation of the services rendered by Daniel Donovan, Esq., M.D., and Mr. Jeremiah Crowly, the Medical Officers of the Institution, during the long period of their connexion with it (nearly eighteen years); during which time, and especially within the last six years of famine and epidemic disease, their attendance upon the sick and afflicted of this large and very impoverished district, has been marked by high medical skill, and by unwearied zeal and humanity.

That the present opportunity (the last we may have in connexion with this Dispensary) is gladly seized on by us to give unanimous expression to the high respect and esteem in which we hold their professional abilities, as well as their personal characters; and our earnest hope that the poor of our district may, under any new arrangements, continue to enjoy the benefit of their kindness and skill as heretofore.

Signed on behalf of the meeting,

D. MCCARTHY, Chairman.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D.,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.
☞ *Change of Proprietorship.*
BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of
THE ROYAL MEDICAL HALL,
beg particularly to state, that henceforth
THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,
will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,
BEWLEY, OWEN, AND CO.'S ESTABLISHMENT
embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,
of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT
is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 3, will be published, price Sixpence, free by post, each volume complete in itself,
Enlarged to twenty-four folio pages,
The First Number for 1852, of the
GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;
A Weekly Record of Rural Economy and General News.
The Horticultural Part Edited by Professor Lindley.

The Farming Part (under the Editorship of a Practical Farmer) treats of—

The Practice of Agriculture,	Management of Stock,
Agricultural Science,	Veterinary Science,
Animal and Vegetable Physiology,	Drainage,
Improvements in Implements, described by woodcuts whenever requisite,	Irrigation,
Better modes of Husbandry,	Foresting,
Results of Experimental Farming,	Road-making,
Growth and Rotation of Crops,	Farm Buildings,
	Labourers,
	Treatment of Poultry,
	Agricultural Publications,

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are
Weekly Calendars of Gardening Operations,
Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It, moreover, contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make *The Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive *record of facts* only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions: their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any Newsvender.

Mr. TRANT, President of the College, in the chair.

CASE OF DROPSY OF THE LEFT FRONTAL SINUS, OCCASIONING CONSIDERABLE DILATATION OF THE SINUS, WITH ABSORPTION OF ITS BONY PARIETES; EVENTUALLY FORMING A TUMOUR EXTERNALLY, WHICH PROTRUDED THE LEFT EYE DOWNWARDS: WITH OBSERVATIONS.

By O'B. BELLINGHAM, M.D., F.R.C.S.,
One of the Surgeons of St. Vincent's Hospital.

DR. BELLINGHAM said the subject which he proposed to bring under the notice of the Society on that occasion was disease of the frontal sinus. Spontaneous disease in this situation was confessedly very rare; and the peculiar form of disease presented by the patient whose case he was about to detail, had not, he believed, been hitherto described; at least in the researches which he had made, he had not been able to find a similar one recorded. The cast upon the table, taken by Dr. Carte, represented accurately the appearance of the patient on his admission into hospital.

James McCleary, aged 46, "a small farmer" from the county Monaghan, admitted into St. Vincent's Hospital, July 11, 1850, on the recommendation of Dr. Morrison.

A tumour, about the size of a lemon, measuring nearly five inches transversely, and above three inches from above downwards, occupies the forehead above the root of the nose and the region of the eyebrows, extending from the middle of the right eyebrow to the temporal side of the left, which protrudes downwards the left eyeball, and partly conceals it. The tumour is not painful when handled, and the skin covering it is not discoloured; the centre and the lower part are soft, and to the touch give the sensation of fluid; at the upper part, on each side, a ridge of bone is felt along its margin, extending a short distance upon its walls. The sight of the eye is not impaired, and he has not suffered pain except at one point, on the left side near its margin.

The patient states that he had been always healthy, and never received an injury in the part; he attributes the disease to cold. He says that about the middle of March, 1848, he was employed in plowing, the weather being very harsh, when he caught cold, "a scum came over his eye," and his sight was affected. About two or three months afterwards he perceived a slight swelling on the forehead above the left eyebrow, which increased gradually in size. In February, 1850, he applied at the Monaghan Infirmary, when Dr. Young introduced a small trocar, and withdrew about an "eggshell full" of fluid, which had a dark colour. In May last it was again tapped with the same result; and he states that the swelling was very considerably reduced upon each of these occasions. The left testis is atrophied, and about the size of a hazel nut, the effect of an injury which he received when twelve years of age.

The patient being very anxious to submit to any operation likely to afford relief, and to remove the deformity, it was determined, in consultation with Sir Philip Crampton, as there was doubt about the nature and seat of the disease, to expose the tumour by a free incision of the integuments, and then to act according to circumstances.

July 19, 1850. A transverse incision was made through the integuments in the whole length of the tumour, which were dissected back above and below. An opening was then made into the tumour, and a quantity of a dark-coloured, viscid fluid, having much the appearance of bile, and amounting to several ounces, escaped. The cavity left was found to be formed by an expansion of the left frontal sinus. The anterior table of the bone here had been entirely absorbed, except at the margin where the hard ridge had been felt. The posterior table of the bone had been also absorbed, and the pulsation of the brain was visible to the eye and perceptible to the touch. The orbital plate of the frontal bone had been likewise absorbed, and the globe of the left eye could be felt from the cavity of the sinus. The interior of the cavity presented a smooth, white, and glistening surface resembling the dura mater.

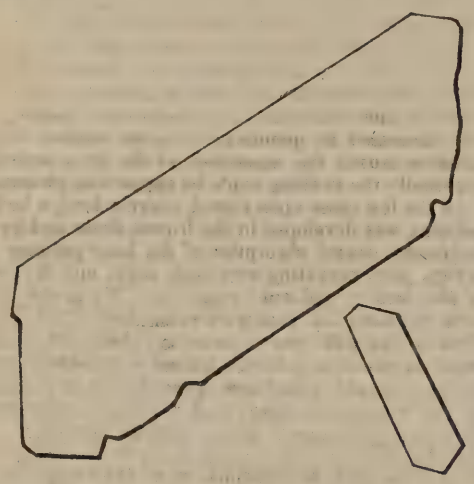
Only one point in the interior gave out blood, and this but to a small amount; the incision in the integuments, however, bled freely, and required several ligatures.

A dossil of lint was placed upon the bleeding point in the cavity, and the wound was not dressed for some hours,

when it was removed; the edges of the incision were then brought into contact, and retained by a few points of the interrupted suture and adhesive plaster.

The fluid removed resembled bile in appearance and consistence, or the fluid sometimes evacuated from ovarian cysts which have frequently been tapped. On a microscopic examination by my friend Dr. Carte, it was found to contain granular matter, oil, and blood globules (the latter being derived from the wound in the integuments which had mixed with it as it escaped), with a large number of tabular crystals of a peculiar shape, somewhat resembling cholesterine.

The accompanying woodcut, from a drawing by Dr. Carte, gives an accurate representation of two of these crystals, magnified 200 diameters.



20th. The integuments covering the tumour, which were quite flaccid yesterday, are now tense and distended; both eyelids are œdematous, and the eyes are closed; the integuments of the forehead are red, and the edges of the wound are glued together. Two of the sutures were therefore removed, and the lips of the wound separated to a small extent when exit was given to a quantity of serous fluid slightly tinged with blood. A piece of cotton wick, to act as a syphon, was then introduced into the cavity; pulse 64. A grain of calomel and two of James's powder were directed to be taken three times a day.

22nd. The swelling and œdema of the eyelids and forehead have diminished; a serous fluid slightly tinged with blood continues to escape, and the pulsation of the brain, acting upon this fluid and pushing it forward, is very evident; pulse 72; thirst less; tongue cleaner.

23rd. The patient complains of pain over the brow on the left side, which has a dull character; he says he occasionally feels pain of a darting kind in the same part, and that the parts above the wound feel as if benumbed.

25th. A portion of the wound has healed by the first intention; the discharge is thicker; the œdematous swelling about the wound has altogether subsided; the patient complains of no pain, and is in better spirits; pulse under 70; little thirst.

26th. Patient not so well to-day; there is a redness over the forehead, particularly over the site of the tumour, of an erysipelatous character; the skin is hot; the bowels are confined; pulse 84; he complains of pain in the head; slept badly, and is in low spirits. Warm water was injected into the cavity by means of a gum elastic bottle, and a good deal of healthy looking pus washed out, with relief to the patient.

30th. The nose and left cheek present now an erysipelatous redness; the skin is cooler; pulse 76; tongue coated, and gums slightly affected by the mercury, which was directed to be discontinued; the discharge of healthy pus continues, and the cavity is syringed out with warm water daily; he complains now of cough and "oppression of his breathing;" a good deal of mucus is secreted in the bronchial tubes which gives him trouble to expectorate; he says he has been subject to a cough in the winter; the ligatures have all come away, and the wound is united, except at the point where the tent is introduced. The patient is still upon very low diet.

31st. The erysipelas has now extended to the right ear and right side of the face; tongue somewhat less coated; patient has had rather profuse perspiration over the whole body for the last few nights. A mixture, containing quinine and dilute sulphuric acid, was directed.

August 2nd. The erysipelas has almost disappeared; the patient's tongue has cleaned; he has no pain now; the discharge has diminished, and is of a healthy character; the patient only complains of hunger and weakness, as he has been upon a very low diet; the perspirations ceased after one dose of the medicine.

6th. The skin of the face is desquamating; the discharge from the cavity has diminished; the tongue is clean; the patient complains of no pain, and was permitted to leave his bed to-day for a short time.

9th. The patient has been up every day since the last report; he feels perfectly well, and is in good spirits; the cavity is filling up, and the discharge from it very trifling.

19th. The cavity is almost filled up; water injected into it returns immediately; there is scarcely any discharge, and the little orifice is with difficulty kept open by the tent; the patient is remarkably well; the tongue is clean; the appetite good, and the bowels are regular.

21st. The patient was allowed to return home to the country to-day; he remained well when heard of some time subsequently.

OBSERVATIONS.

In the infant at birth there is no trace of the frontal sinuses; between the age of two and three years, they begin to make their appearance, when they constitute merely larger cells in the diploe. They are not fully developed until about or after puberty, when they consist of two cavities, often of different size, and varying also in size in different subjects, which sometimes communicate with one another, but always with the nasal cavities by a separate foramen in each, which opens into the middle meatus of the nose.

The development of these sinuses is the result of the receding of the two tables of the bone from one another; or more properly speaking, of the advance forward of the anterior table, and it is in some measure from the development of these sinuses that the change in the profile of the face, which occurs at this period of life, is brought about.

The frontal sinuses are lined throughout by mucous membrane, which is continuous with the pituitary membrane lining the nasal cavities; but it differs from the latter in being denser in its texture and paler in its colour, as well as in being smoother and more highly polished. In the infant at birth, as there is no trace of these sinuses, so of course this membrane is altogether absent at this period.

The membrane, then, which lines the frontal sinuses, although it is considered to be a continuation of the pituitary membrane of the nose, would appear to be developed subsequently to it; and it differs from it not only in appearance, but in its liability to disease; for while spontaneous disease of the mucous membrane of the nasal cavities is sufficiently frequent, disease of the membrane which lines the frontal sinuses is excessively rare.

The frontal sinuses from their position are exposed to injuries from cutting, puncturing, or other instruments, from blows or falls, &c.; and inflammation followed by suppuration may be the result of such injuries, but appears to be rarely so. Some few cases are also upon record of inflammation ending in abscess in the frontal sinus independent of injury, in which the matter either made its

way into the nose, and so escaped, or was retained, and gave rise to a train of severe and distressing symptoms. A graphic description of a case of this kind will be found in the second volume of the Principles of Surgery by John Bell.

The works of the older authors contain cases, or allusions to cases, where anomalous or alarming symptoms, amounting in some instances to convulsions or maniacal delirium, were produced by insects finding their way into the frontal sinuses, or by worms developed in these cavities, which symptoms ceased upon the escape of these animals by the nostrils. The majority of such cases are, however, badly authenticated, or the details are too imperfectly given to render them of much value; and as analogous cases have not, that I am aware, been met with by modern surgeons, it may reasonably be doubted whether the symptoms were always due to the cause stated. Indeed the membrane which lines the frontal sinuses does not appear to be endowed with very acute sensibility; in the case before us at least, this membrane was exposed and handled without any particular sensation being experienced by the patient. Besides we know that in certain animals, particularly the dog, a species of entozoon, the pentastoma tœnioides, is developed, aad has its natural habitat in the frontal sinuses. The specimen upon the table was presented by me to the Museum of the College.

The analogy between the membrane lining the frontal sinuses and that of the cavities of the nose, is shown by the occurrence of polypi in the former cavities. This, however, is excessively rare, so rare indeed that I believe there are only three examples of it upon record, and an interval of one hundred years intervened between the occurrence of the first and second cases; two of them, moreover, were complicated with nasal polypus.

The first of these cases occurred at La Charité in the year 1725, it is detailed by Levret, the inventor of the canula, and is quoted by Boyer in the sixth volume of his Surgery as the only example he knew of polypus of the frontal sinus. In this case polypi existed in the maxillary sinus, in the nose and throat, as well as in the frontal sinus. The second case was published in the *Journal de Rust* in the year 1825: the sinus was trephined, and the polypi removed by incision. The remaining case is reported by M. Wuth in a work on surgery, published in Berlin in 1844; it has been quoted at some length in the twenty-first volume of Dr. Forbes's Review, and is stated by the writer to be the only case on record where a polypus was extracted from the frontal sinus with success. This patient, who was a boy of ten years of age, is stated to have laboured under the disease for nine years; but this must be a mistake, as the frontal sinuses are not developed at that early age; during all this time he is said to have suffered from severe pain in the head; the "regions of the frontal and nasal bones were greatly protruded, and the left eye was so entirely pushed forwards out of the orbit that it lay on a level with the back of the orbit." Dr. Wuth proceeded to operate by making a vertical incision from the nose upwards, and a horizontal one close above the eyebrow, the flaps were dissected up and the trephine applied in two places, when "an immense quantity of polypi protruded." They were removed by incision, and the cavity left was capable of containing three hen's eggs. "The healing of the parts occupied twelve months, the frontal sinus being by that time considerably lessened in all directions, and the eye having partially returned into the orbit."

In two instances upon record hydatids were developed in the frontal sinus, and gave rise to symptoms analogous to those produced by polypi in these cavities. One of these cases was treated by Langenbeck; he perforated the sinus with the trepan, and extracted the hydatids with a forceps. Hydatids, I may observe, have also been developed in the substance of the frontal bone away from the sinuses: a remarkable case of the kind, which was treated by Mr. Keate, is contained in the tenth volume of the Medico-Chirurgical Transactions.

The membrane which lines the frontal sinuses is believed to secrete a mucous fluid, which in the healthy state of the parts finds its way through the foramina opening into the nose. Now, if from any cause, the escape of this fluid was impeded, or altogether prevented, symptoms depending upon its retention might be expected to set in. In practice, however, this is not observed. The accumulation and thickening of the mucus in these sinuses might (M. Boyer says) produce some of the phenomena which result from inflammation and suppuration in it; but "I do not know (he adds) that there exists a single example of it." "It is possible (M. Berard observes*) that inflammation might cause an increased secretion of mucus, and that the passage into the nostrils being obstructed, the fluid would accumulate in the sinus, and produce a state of disease similar to that observed in the maxillary sinus; but no fact of this kind has yet been published."

The history of the present case would, however, lead us to suppose that such may have been the origin of the disease here: the patient stated that he was exposed to cold, which affected the left eye, congestion of the mucous membrane lining the sinus probably followed, obstructing and finally obliterating the communication between it and the nostril, the secretion accumulated, and became inspissated, owing to the absorption of its watery particles; as the fluid increased in quantity, the sinus became dilated, its pressure caused the absorption of the bony parietes, and eventually the swelling made its appearance externally.

In the few cases upon record where a foreign body, as a polypus, was developed in the frontal sinus, and by its enlargement caused absorption of the bony parietes of this cavity, pain, persisting constantly night and day, was one of the most prominent symptoms. We might therefore have supposed that such a distension by fluid of the frontal sinus as was sufficient to cause the absorption of its bony parietes, would have been attended with considerable pain, yet nothing of the kind was observed; the patient suffered only from pain at one point, which was never severe, and all through pain was an unimportant symptom.

Again, where distension of the frontal sinus is caused by pus the result of inflammation of the lining membrane, and where the pressure of the fluid is sufficient to cause absorption of the bony walls of the sinus, the posterior table being the thinnest is supposed to yield first, occasioning compression of the brain to a greater or less extent. Thus Velpeau observes†—"When fluids collect, or tumours are developed in the frontal sinuses, their posterior lamella being the thinnest yields first, quickly causing pressure on the brain." Boyer also, in reference to the same point, observes—"Most frequently in place of the anterior it is the posterior wall of the sinus which yields, because it is thinner and less resisting; it becomes thinned, wears, and at last gives way, when the brain, compressed at first by the swelling of the sinus, is immediately so by the pus. In such cases the abscess of the frontal sinus is almost always accompanied by swelling of the upper eyelid on the same side, and by paralysis of the muscles upon the opposite side."

Now, in the case before us, although the amount of fluid contained in the frontal sinus was sufficient by its pressure to cause thinning, and finally complete absorption of its bony parietes, the anterior wall was the one to yield, and the brain did not, at any period, suffer the slightest pressure.

In most treatises on surgery, morbid states of the frontal sinus are either very cursorily alluded to, or all notice of them is omitted. The only diseased conditions of these parts mentioned by Boyer are, wounds, inflammation and suppuration, polypi, and the presence of foreign bodies, including insects and worms. Hydatids have also been observed in two or three instances, as have tumours presenting the characters of vascular nævi. But I have not been able to find any diseased state described analogous to that presented by this patient; and as the dilatation of the

* Dict. de Medécine, tome 28, 2nd edition, 1844.

† Anatomy of Regions, translated by Hancock, 1838.

maxillary sinus, caused by the accumulation of its secretion, has been named by Dubois and Boyer "*Dropsy of the Maxillary Sinus*," the morbid state of the frontal sinus, which I have described, would perhaps not inappropriately be termed *Dropsy of the Frontal Sinus*.

Dr. MAGUIRE stated that a few days ago he saw a very interesting case of fracture of the frontal sinus, the patient being a man who met the accident by falling upon a large stone; and not the least curious feature of the case was, that he seemed to think far less of the fracture itself, than he did of the large tumour in each nostril, by which the latter were blocked up, and his breathing greatly obstructed. On pressing the nose, matter to the extent of an ounce and a half came out through the wound in the frontal sinus; and then he concluded—though he first supposed it might be a case of nasal polypus,—that it must be an abscess of the sinus itself. Pressure was then applied to the nose, and poultices to the wound, and at the end of one week, the patient, contrary he might say to his expectation, was quite well. In the first instance he thought it would be desirable to puncture the tumour, but on further consideration he determined to try the effects of a milder course of treatment which, he was happy to say, was attended with the most favourable results.

Dr. STAPLETON said that if he had been aware that Dr. Bellingham had intended to bring forward his interesting paper on that occasion, he would have availed himself of the opportunity to present to the Society a valuable cast which he had for some time past in his possession. It was taken from a boy who had a tumour at the situation of the frontal sinus, or rather on the upper part of the nose. The patient was admitted into Jervis-street Hospital; and on examination of the tumour, he found that it had a doughy feel, and that on compressing it between the fingers, it receded backward towards the sinus, but returned again to its former site, as soon as the pressure was removed. The patient had been in several other hospitals before he was taken into the Jervis-street Infirmary, and possibly some of the members present might recollect having seen him elsewhere. He was anxious to puncture the tumour, but several surgeons, to whom he showed it not being able to make up their minds as to the precise nature of the case, he was afraid to venture on such a proceeding. It was perfectly colourless, had none of the appearances of a varix, and there was nothing like a pulsation to be detected in it, by which the tumour could be connected with the brain. He showed the case to many experienced surgeons, but none would advise him to make an exploration for the purpose of deciding the nature of the disease.

Dr. BENSON asked the age of the patient.

Dr. STAPLETON said he might have been 12 or 14. He appeared to suffer no pain whatever, except when pressure was made on the tumour.

AMPUTATION AT THE HIP-JOINT.

By J. F. MAY, M.D., Professor of Surgery in the National Medical College of Washington, and one of the Surgeons to the Washington Infirmary.

IN the early part of November, 1850, I was requested by Dr. Morgan of this city, to visit Richard Eaton, who, he informed me, had been bedridden for many months, from disease of the os femoris and knee-joint. After examining the limb, I advised that he should be removed to the Washington Infirmary, for the purpose of having it amputated, to which he consented, and the following is an abstract of his case:—Richard Eaton, aged 37, fisherman, entered the Washington Infirmary on the 5th of November, 1850. In August, 1847, while on a fishing excursion down the river, discovered a small lump about the size of a filbert below the right knee. The swelling was accompanied with much pain, and continued to increase, until the entire joint and contiguous parts of the thigh were very much enlarged. In March, 1850, it suppurated, and discharged very freely, which gave him some slight relief, but in the month of May he was obliged to confine himself to his bed, from which he has not arisen since that period. At this time there are as many as four deep sinuses extending down to the shaft of the bone, and opening by fungoid orifices on the thigh. The thigh is throughout enormously enlarged, *to at least twice its natural size*, and is œdematous up to the groin, and very much inflamed in its middle and superior portion. The knee-joint has long since been destroyed by ulceration, to such an extent, that the foot falls on either side, unless supported. The discharge of pus from the different sinuses and the joint is very great (at a moderate computation at least half a pint a day), and the part presents a most disgusting aspect, from the free generation of maggots in the limb and joint. His pulse is now 106. He has burning in the hands and soles of the feet regularly as evening approaches. He had an attack of diarrhœa in July last, which was very severe, and lasted fourteen days. Since that time he has not been troubled with it. His digestive organs are now in a tolerably good condition, notwithstanding that he takes from three to six teaspoonfuls of laudanum every night before he can get any rest. With the exception of the diseased limb, his whole frame is very much emaciated, and in appearance he is anæmic. He has a bedsore over the sacrum about as large as a twenty-five cent piece, deep, and for several inches around it the integument presents an angry and livid colour. In his habits he has always been temperate. A nutritious diet, principally of animal food, was ordered for him, and the following powder to be taken three times a day:—℞ Quiniæ sulphat., ammon. carb. g. camph., āā gr. ij. M. To be taken each time in a tablespoonful of brandy. At night tinct. opii ʒiij. to compose and relieve him. I did not of course think it prudent to stop, although I diminished the opiate, to which he had been so long accustomed. His stomach revolting at the carb. ammoniæ and camphor, they were discontinued in a few days, and five grains of the sesquioxide of iron given with the quinine and brandy. The bedsore was dressed with the cerat. zinci carb., and pressure removed from it by a circular cushion, and he was placed on a air bed. This treatment was continued until the 14th of November, when his condition having slightly improved, I decided on removing the thigh at the hip-joint for the following reasons:—1st. The soft parts are diseased to such an extent that it is impossible to get a proper covering for the bone, except in its upper portion, and even here, and as high up as the groin, the tissues are enfeebled and œdematous. 2nd. The shaft of the femur can be detected in a very diseased state high up, and I believe from this fact, in connexion with the state of the soft parts, and the long duration of the disease, that the cancellated structure of the entire bone is involved, and my colleagues concur with me in this opinion. The patient, aware that he could live but for a few weeks, was perfectly willing to submit to the operation, though told that he might, in his debilitated condition, die on the table. The operation was performed on the 14th of November, in the presence of the medical class and a number of professional gentlemen, in the following way: The patient in a state of complete anæsthesia from chloric ether, was brought into the amphitheatre, and laid on a narrow table, the nates projecting well over its edge. The artery was compressed by an assistant with the thumb against the pubis. The limb (which from its size required to be supported by two assistants) was then slightly raised, and flexed upon the pelvis, so as to relax the muscles on the anterior and upper part of the thigh. The testicles being drawn well upwards out of the way, and the sound limb to the opposite side, a long and narrow one-edged knife nearly twelve inches in the blade was then introduced, a little above the *tuberosity* of the *ischium*, carried as near the neck of the bone as possible, and pushed out on the opposite side, about one inch and a half below the *anterior superior spinous process of the ilium*. A flap between six and seven inches long was now cut downwards from the front of the thigh. The knife was of course passed much beneath the femoral vessels, and they were consequently not divided until the lower edge of the flap was being cut; this enabled an assistant to pass his hand into the upper

part of the incision, back of the knife, and thus to grasp and securely compress the femoral artery *before* it was divided by the passage of the knife downwards. This flap was now raised and drawn forcibly upwards by the same assistant, the femoral artery being still so securely held by him that scarcely a drop of blood escaped from it or its branches. To prevent the fingers from slipping, a soft piece of rag was held against the cut surface. The thigh was now abducted and forcibly depressed by the two assistants having charge of it, so as to throw the head of the femur forwards, and from the acetabulum as much as possible, and the knife was carried across the capsular ligament, until it was freely divided. The head of the bone now started from the acetabulum, the round ligament was divided, the knife passed behind the head, and a posterior flap cut a little longer than the anterior. As soon as the limb was removed, the vessels in the posterior flap were compressed by sponges held against them, until they were separately tied. Ligatures were applied to them first, and then the femoral, the profunda, and smaller branches in the anterior flap were secured. Ligatures were applied in all to twelve arteries.

Hæmorrhage having been completely arrested, the edges of the flaps, on account of their great size and weight, were approximated by four points of the twisted suture, with broad adhesive strips in the intermediate spaces, and water-dressing was applied over the wound. Not more than eight ounces of blood were lost in the operation.

The operation itself was performed in half a minute; and I was most ably assisted in it by my colleagues, Professors Miller, Johnston, and Stone, and Drs. Wotherspoon and Coolidge of the United States Army, to whom my thanks are due for the very important aid which they rendered me.*

The patient did not evince the slightest consciousness during the operation, and on being told, when he awoke, that the limb was removed, he expressed great surprise. The wound being dressed, he was removed to his bed, and the simple water-dressing was ordered to be continued, and four teaspoonfuls of tinct. opii were given to him at about half-past three p.m., this being about the usual quantity which he was in the habit of taking before he entered the infirmary. Eight p.m. Pulse 98; not having been composed by the first dose of laudanum, ʒiij. more were given.

Nov. 15th. Slept four or five hours during the night, and feels better; spirits good; pulse 96; took for breakfast tea and toast, and a soft boiled egg; has been a great smoker before and during all his illness, and asks to be allowed a cigar—granted; at dinner chewed a few mouthfuls of beefsteak, and took some coffee and dry toast; dry toast and tea for supper. Nine p.m. Pulse 104 to 106. Soft compresses soaked in warm water ordered to be applied to wound every few hours, and covered with oiled silk, to prevent too rapid evaporation; bedsore dressed with the cerat. zinc. carb., and over this adhesive plaster. Ordered tinct. opii ʒiij.

16th. Slept again about five hours during the night; took coffee, dry toast, and soft boiled egg for breakfast, and feels better; pulse 90, soft and regular, and skin moist; warm-water dressing continued, and bedsore dressed as yesterday; at dinner, took a few stewed oysters with a cup of coffee and dry toast, and smoked a cigar. Eight p.m. Pulse 88; wound discharging quite freely; discharge thin, and slightly coloured; took coffee and dry toast for supper. Ordered tinct. opii ʒiij.

17th. Slept well last night; pulse 88; same dressing to wound and bedsore continued; took out one of the sutures; took same breakfast as yesterday, and with appetite; wound looks well, and union appears to have taken place in a large portion of it; for dinner, chicken soup and a small piece of boiled chicken, which he desires; has had no passage from his bowels since the operation. Ordered ol. ric. ʒss., mist. camph. ʒij., aq. menth. q.s. M. ft. haust. Seven p.m. Has had two healthy-looking evacuations from bowels; urine clear and healthy looking; pulse 96. Continue iron, brandy, and quinine; at bedtime tinct. opii ʒiij.

18th. Has slept well; pulse 86; tongue moist and clean; took same breakfast as yesterday; removed remaining sutures, and applied fresh adhesive strips to sustain the edges of wound; free discharge from it; same dressing continued. Ordered half a pint of oysters for dinner. Eight p.m. The pulse 86; some pain in stump. Ordered tinct. opii ʒiij.

19th. Pulse 100; has not slept well, but took his usual breakfast with appetite; discharge from wound free, thin, and brown; same dressings continued. Eight p.m. Pain in stump. Give ʒiij. tinct. opii. Pulse 86; spirits good; had a healthy and natural evacuation from bowels in the afternoon; ate for dinner to-day two roasted Irish potatoes, and a small piece of roasted chicken, and smoked during the day two cigars.

20th. Has slept some and looks better; pulse 86; took his usual breakfast, only substituting tea for coffee; wound discharges very freely; same dressings to it continued. Ordered for dinner have a pint of stewed oysters, with roasted potatoes, and allowed two cigars during the day. Eight p.m. Considerable pain in stump; pulse 84. Ordered tinct. opii ʒiij.

21st. Has passed a bad night, very restless and starting in his sleep; countenance expressive of much suffering; pulse 100; very free thin discharge from wound; four of the ligatures on small vessels in the lower flap came away this morning, and considerable hæmorrhage followed; partially opened the wound, and removed a recent coagulum, and also a quantity of very dark and offensive coagulated blood that had evidently oozed out soon after the operation, probably from the acetabulum, as it lay in contact with it; arrested the bleeding, which was quite free, and proved to be from the ischiatic artery; reapplied water-dressings, and ordered tinct. opii ʒiij. Eight p.m. Pulse 108; has taken his usual supper, and has a small stool to-day; stump hot. Apply cold-water dressing.

22nd. Has had a good night; pulse 102 to 104; ate his usual breakfast with relish; stopped the brandy to-day, and ordered in its place a wineglassful of London brown stout, with five grains of protocarb. ferri, Vallet's (in place of the sesquioxide and quinine, which he has been taking), three times a day; half a pint of stewed oysters for dinner, and may smoke his cigars as usual. Eight p.m. Pulse 102 to 104; easy; took his meals with a good relish to-day, and says he feels better and stronger. Ordered tinct. opii ʒiij., and ʒij. more to be taken in the night if restless and unable to sleep. The additional dose was allowed, because for the two or three nights past he has not been able to sleep as well as usual.

23rd. Slept well after taking the second opiate, being very restless before; discharge from wound more consistent and healthy; allowed for dinner a tender piece of beefsteak and two potatoes, and during the day two cigars. Eight p.m. Pulse 98; has had a very comfortable day, and is in good spirits. Tinct. opii ʒijss., and a smaller dose to be repeated late if necessary.

The treatment which is here given for the first nine days after the operation was continued, with slight variations, for the four succeeding weeks. The last ligature came away on the 14th of December. On the 25th he sat up in bed, and on the 29th in a chair, and was wheeled about the room and passage. On the 31st the stump was almost entirely healed, and he was able to sit up a couple of hours

Immediately after its removal the bone was sawed through longitudinally by Professor Stone, and the entire cancellated structure extending through the trochanters, the neck, and the head, was found to be very much softened (cheesy) and filled with pus. The external table in this the upper third of the bone did not seem to be much involved, though below it was much affected, but the cancellous portion was throughout a mass of disease. The cartilages covering the head and lining the acetabulum were smooth and healthy in appearance. The soft parts were infiltrated with serum throughout the whole limb, which continued to ooze from it very freely for many hours after its removal. The muscles were pale and flabby, and in the lower half of the thigh they were blended together and disorganized.

at a time, and on the 1st of January he moved about the room on crutches for the first time. From this period he improved more rapidly in flesh and strength, and he left the infirmary on the 26th. On the 17th of February I called at his house, and found that he was out and able to attend to business, in which he is at this time (July 18th) actively employed, and supporting by it a large family. The stump continues to be perfectly sound, and he says that his health is as good as it ever was. In all respects, he presents the appearance of a strong and vigorous man.—*Amer. Jour.*

POISONING BY DATURA STRAMONIUM.

By Dr. Breweston of Doncaster.

Early in the afternoon of the 14th of October, I was summoned to see two children of the respective ages of five and three years, who were described by the messenger as having suddenly "gone out of their heads." They had been picked up in the street in this state, and carried into the house of the stranger.

I immediately recognized the symptoms of poisoning by one of the *Solaneæ*. The face was flushed; the eyes were staring and brilliant, and the pupil was fixed and excessively dilated. There was complete loss of vision, imperfect control over voluntary muscular action, and violent delirium, which was alternately mirthful, furious, or dolorous, directed to some imaginary source of pleasure or repugnance, and accompanied with corresponding gesticulations. The tongue was occasionally thrust from the mouth, and the throat, which appeared to be the only sensible seat of discomfort, was grasped and torn by the hands, as if the patients imagined it to be oppressed by some foreign body. Their attention could not be aroused to anything which was said, and they resisted all attempts at interference with piteous cries or violent struggling.

I suspected the poison of belladonna, and caused search to be made in the neighbourhood for the berries of that plant, administering emetic doses of sulphate of zinc in the meantime. The patients exhibited apparent reluctance to swallow, keeping the jaws rigidly closed, and resisting the administration of the remedy with their hands, though they were not sufficiently conscious properly to direct such efforts. The stomach was slow to act, but after considerable perseverance vomiting was induced. Numerous seeds of *datura* were detected in the ejecta; indeed a much greater quantity than has been known to cause death.

It seemed, from the search which had been made, that the poisonous herb had been thrown out from a neighbouring garden, and several emptied and divided thorn-apples were discovered. A third child confessed to having eaten a smaller quantity of the seeds, and she was slightly though not alarmingly affected. The poison having been retained four or five hours when vomiting took place, a sharp aperient dose was administered, which, after some hours' delay, acted moderately. Cold was from the first assiduously applied to the head.

At five p.m. four hours from my being first called in, though the symptoms were somewhat abated, vision and consciousness to external things were not restored, and the delirium returned at intervals with nearly all its previous violence. The parents of the children, who were now present, were not noticed by them, save occasionally to be embraced or attacked for some imaginary benefit or injury. I subjected the patients to a shower-bath, and applied a blister to the back of the neck.

At nine vision was partially restored in the elder child, and the *hallucinations* were in a great measure supplanted by *illusions*, which indicated some return of consciousness.

At eleven the delirium had become of a muttering type; the patients were drowsy, and displayed a comatose tendency. In the elder child *the pupil, though contracted in the dark, gradually dilated to the stimulus of light.* Sinapisms were now applied to the feet, calves, &c. Alternate doses of strong tea and ammonia were given; the face was occasionally sprinkled with water, and other means were used to prevent sleep.

At five o'clock the ensuing morning, the victims were allowed to sleep, and both awoke before noon, perfectly conscious and well.

On the morning of the third day, the body of the younger child became covered with a small papular eruption, which continued for several days, accompanied with fever.

The effects of the poison were *purely nervous.* The *cerebrum* was first affected; hence arose perverted vision, illusive delirium, and, as consciousness diminished, pure hallucinations. The derangement next attacked the *cerebellum*, as was shown in the loss of control over voluntary muscular action.

Finally, the *medulla spinalis* was implicated, as was evinced by the spasmodic motions of the extremities, &c. In each organ, the first effect seemed to be *stimulation.* This was followed by *perversion*, and lastly, by *depression*, and threatened *extinction* of the function.

It is then incorrect, with such evidence as the above recorded symptoms present, to class *datura* among the *narcotico-irritant* poisons. This term has been vaguely applied by toxicologists to several poisons which are in no proper sense of the term irritants; and which only differ from the *narcotics proper*, either in affecting more peculiarly the spinal cord, or in the stimulating effects—the first result of all narcotics—being more marked or of longer continuance than the narcotism which follows. Death may even occur from over stimulation, before the depression sets in. I have, for instance, poisoned animals with Indian hemp, some of which have died in a state approaching to *tetanus*, while others have survived this stage to perish by *coma*, or, at least, by *nervous depression.* It is probable that a poisonous dose of *strychnine*, if it did not first kill by over-excitation of the spinal cord, would eventually do so, like *aconite*, by depression of that organ.—*Prov. Jour.*

DEATH FROM INJURY TO THE KIDNEY.

(Under the care of Mr. Stanley of St. Bartholomew's Hospital.)

John T——, aged 43, a corn-factor, of moderately strong constitution and temperate habits, was admitted, at three p.m. on the 4th of November, 1851, under the care of Mr. Stanley. The patient states, that about one a.m. as he was driving in a gig, a cab travelling at a rapid rate came in contact with his vehicle; he was thrown out, and fell on his back. The patient cannot say whether he struck against any very hard substance, but he was not stunned, and quickly recovered from the shock. Immediately, however, a severe pain in the loins was felt; this has since continued, without intermission; and about seven hours after the accident, the patient passed nearly *two pints of pure blood* "per urethram."

On his admission, he presented the following symptoms:—Conjunctiva, face, upper part of the body, and arms, of a *yellow tinge;* skin hot and dry; pulse small, sharp, and quick; tongue clean and moist. The bowels had been copiously relieved at noon, but shivering had existed more or less since the accident; there was no sickness, but much thirst. The patient has not passed any urine since the sanguineous discharge above mentioned. Pressure over the right lumbar and hepatic regions gives intense pain; but the surface is not at all ecchymosed. Mr. Stanley ordered some brandy, and the loins to be cupped to ten ounces in a few hours.

On the next morning, it was found that the patient had not slept; dark-coloured urine had been passed; the pain was not so distressing, but the colour of the skin was the same. Mr. Stanley ordered milk diet; eighteen leeches over the right hypochondrium; castor oil immediately; and three grains and a half of mercury and chalk every six hours.

On the second day after admission, the symptoms had not altered, except that the pain had diminished over the liver, though it persisted as intense as before in the right lumbar region. At eight in the evening of this day, the patient passed a pint of nearly pure blood, which coagu-

lated soon afterwards; and he complained of pain in the epigastric region, with ineffectual attempts to empty the bladder. A catheter was passed, and brought away a pint of urine, deeply tinged with blood. The bowels having been freely opened, the mercury and chalk were continued, with the addition of opium.

On the third day the pain in the back was not so acute, but more diffused; and pressure over the hepatic space gave no pain; there was a desire to pass urine, but none could be obtained by means of the catheter. The bladder was now injected with a small quantity of tepid water, but no urine was evacuated until a long, full sized elastic catheter was used, when twenty-eight ounces of urine, mixed with blood, were drawn off. The bladder was washed out with warm water until the fluid came away quite clear; these measures gave the patient much relief. In the course of the following night he was suddenly startled by great pain in the back and hypogastrium, and this becoming hourly more severe, a catheter was passed, and twenty-five ounces of urine, mixed with blood, evacuated, with immediate relief of the pain. The bowels having been cleared with castor oil, Mr. Stanley ordered quinine, with discontinuance of all other medicines; the diet to consist of beef-tea. The urine was drawn off every sixth hour, the quantity varying from sixteen to twenty ounces, and the sanguineous colour remaining the same.

On the sixth day there was a little improvement; the pulse was 100, soft (it had been sharp and jerking for several days), and the skin still very yellow, though the nails retained their natural colour. The urine now became ammoniacal, and Mr. Stanley ordered five grains of gallic acid to be taken every four hours in infusion of matico. It was noticed that the alvine evacuations were pale, and streaked with blood; the gallic acid was not found effectual, as on the two following days the urine brought away by the catheter was as strongly mixed with blood as before; the acid was therefore discontinued, and morphia substituted, the patient being at the same time ordered some wine.

On the tenth day matters looked worse; small quantities of urine (ever mixed with blood) were passed unconsciously, and the patient began to answer questions imperfectly, cerebral congestion and derangement being evidently coming on. He now became restless, attempted to leave his bed in the night; the tongue became brown; the bowels confined; the urine, though clearer, diminished in quantity. The patient became feeble, exhausted, and sank on the thirteenth day after admission.

The body was examined twenty-three hours after death, and presented the following appearances:—Rigidity, but no ecchymosis, except where the leeches had been placed; lungs healthy, but gorged throughout, the finger readily penetrating their texture; liver large, firm, of a pale-brown colour, and loaded with bile. The intestines were glued by old adhesions, the cæcum being firmly fixed in the iliac fossa. On turning aside the intestinal mass a large quantity of bile and urine was found effused in the sub-peritoneal cellular tissue; these fluids were already much decomposed. On examining the right kidney, it was found completely disorganized, a gaping rent extended its whole length posteriorly, and another transversely nearly cutting off its lower third. On the posterior border there was a dark-greenish spot about the size of a shilling, resembling a slough. The left kidney was congested, but quite healthy; the seventh, eighth, and ninth ribs were fractured about an inch from their junction with the cartilages.—*Lancet.*

Strangulated Herina Reduced during Vomiting.—*L'Union Médicale* mentions that Dr. Küttlinger, of Erlangen, in Germany, tried the taxis upon a woman aged 64, whose crural hernia was strangulated, but without success. The patient was soon attacked with vomiting, and whilst she was making efforts, Dr. Küttlinger seized the tumour, pressed it with some force, and succeeded in reducing it in the very midst of the straining. Three months afterwards strangulation occurred again, the taxis was tried in vain, and reduction was effected exactly in the same manner as before.

WOUND OF THE STOMACH WITH PROTRUSION.

By W. Ashby, M.D., of Culpeper, C.H., U.S.

A negro boy, aged 6, the property of Mr. R. B., fell upon a pair of sheep shears, which he had in his hand, whilst running down a hill. The instrument penetrated the stomach obliquely from above, just grazing the left side of the sternum and edges of the ribs, making a flap-like orifice in the integuments. I was called in consultation by my friend, Dr. P. C. Slaughter, and found nearly the whole stomach protruded, and discharging its contents through an aperture about three-quarters of an inch in length. Aware of the controversy which has so long existed among able surgeons, on either side, as to the propriety of stitching the stomach or bowels, the everted edges and gaping appearance of the wound in the stomach made it necessary, I thought, that a stitch should be taken. To avoid irritation, as much as possible, with the finest needle and silk I ventured to take a single stitch through the middle of the wound. Before I saw the case, Dr. S. had made some efforts to restore the organ to its natural position, but it did not occur to me at the time that I should have any serious difficulty in replacing it, at least after enlarging the orifice a little. But such was the unruly nature of the boy—his violent screaming and resistance, the nausea and vomiting which constantly attended the handling of the stomach—that notwithstanding I enlarged the orifice several times to a considerable extent, our best efforts not only failed to restore the organ, but it seemed to protrude the more. At this juncture, fearing the irritation resulting from further efforts, I suggested the use of chloroform, notwithstanding the necessary delay of having to send several miles for it. Whilst under its influence, I found it necessary again to enlarge the aperture slightly, and then had no farther difficulty, although the boy vomited as freely as before from handling the organ. The wound of the integument was rather ragged in its appearance, and of course a little bruised by our efforts. The wound of the stomach was brought directly opposite the tegumentary wound, and gently retained within its verge. A single stitch, patent lint, with cold water and a bandage completed the dressing. The patient was placed on his side, absolute rest enjoined, and soon afterwards a large dose of opium was administered. From the time of the accident until the completion of the dressing six hours intervened, and yet the boy retained his strength most remarkably. Under the influence of the opium our patient rested well the first night.

2nd day. This morning the pulse is a little excited, and face flushed. V.S. to make a decided impression; and this was repeated twice during the day, and opium after each bleeding—absolute diet enjoined—but the boy desires no food.

3rd. The wound had a healthy appearance, but tenderness of the abdomen and tympanitis greatly increased our fears as to the result. The pulse feeble and quick; the bowels not moved since the accident. Turpentine enema and a succession of blisters were ordered, and after the bowels were moved the opium was resumed.

4th. Our patient evidently improved, tympanitis and tenderness diminished, pulse more quiet, countenance and general aspect of things more encouraging; takes a little hot water tea this morning for the first time; gum water and opium continued.

5th. The wound not healed by the first intention; has a dark spot immediately over the wound of the stomach, and is discharging a very offensive sanious matter. A soft poultice, and the same prescription continued.

6th. The ligature came out this morning. The same prescription continued. From this date the boy gradually recovered, without any particular change in the treatment.

Remarks.—1st. It has occurred to me, that possibly it would have been better for me to have restored the stomach, at least partially, before the stitch was taken, as I ran the risk of breaking out the ligature by the subsequent efforts at reduction; and I am sure that the accumulation of gas, though some escaped with an audible sound several times, did not increase the difficulty.

2nd. This case was admirably adapted to the use of chloroform, and illustrates most happily its incalculable value, when used with discrimination.

3rd. As your journal is eminently practical in its character, for the benefit of the younger members of the profession it may not be amiss to allude briefly to what I conceive to be a most important principle in our profession, viz., that an *inflamed or diseased organ must have rest.* In this case, the stomach, instinctively sensible of its wounded and disabled condition, refused most emphatically, for four days, to receive any nourishment—not even gum water—and but very little of anything for about ten days, notwithstanding the entreaties of master and friends, contrary to our orders.

An inflamed eye instinctively excludes the light from itself, so that the physician who interrogates Nature intelligently, at once gets the idea of confining his patient to a dark room, and thus putting the organ entirely to rest. When the lungs are inflamed the patient breathes as much as possible by the abdominal muscles, and lymph is thrown out, gluing the organ to the side, doubtless to prevent motion and friction as much as possible. The same thing is true of inflamed bowels; and because some constipation, the result of this principle exists, I have known great error—and I may say even death—to result from goading and stimulating the organ with drastic purgatives. This principle of rest is susceptible of very extensive application in practice; and any inflammation can be cured, I believe, to which it can be applied. The immortal Physic, always true to the laws of Nature, recognized this principle in the treatment of coxalgia and other diseases of the joints. In conformity to this important law of the animal economy, in the above case, we gave opium freely, to prevent nervous and vascular reaction; and by thus aiding in keeping the wounded organ in a profound state of repose, it contributed, it is believed, no little to the favourable result.—*Stethoscope, Virginia, United States.*

POISONING BY BI-CHROMATE OF POTASH.

By Mr. West of Poole.

Very lately I was requested to visit a professional friend residing in Poole, who had inadvertently tasted a solution of the bi-chromate of potash. The quantity he swallowed did not exceed a teaspoonful, if it were as much. He discovered his mistake shortly afterwards, but did not experience any ill effects until about half an hour, when he felt sick, his countenance became pale, and he became quite prostrate. He being at a midwifery case at the time, was compelled to leave, and requested me to attend on his behalf. Before the delivery of the woman I was sent for to him. I found him in bed; he had been profusely sick, and had thrown up a serous looking fluid, resembling the evacuations of rice fluid in cholera; diarrhœa constant, and the evacuations passing away involuntary; the bed was perfectly swamped; cramp in his legs, thighs, and in the region of his heart; great prostration; pulse small and exceedingly depressed, so much so, that I felt a little alarmed at his state. On his arrival at home, and previously to my seeing him, he had taken some warm tea, which increased the vomiting. As the diarrhœa was profuse, I administered the following draught:—R Tinct. catechu., dr. ij.; tinct. opii, m. xl.; tinct. cinnam. co., dr. j.; aquæ, oz. iss. Sit haust.

I also gave him strong brandy and water at short intervals. In about an hour the sickness had subsided, and the diarrhœa was not so urgent; it had produced great debility. Flatus was then oppressing his stomach exceedingly, and I gave him the citrate of potash, which relieved him much; he had also a warm bath. Before the close of the day, all his symptoms were relieved. He took some arrow-root, and afterwards procured a little sleep. When calling on him in the morning, I found he had passed a good night, and was sufficiently recovered to resume his professional duties. I put this case on record, as poisoning by crome or its preparations is of rare occurrence. Professor Taylor, in his excellent work on Medical Jurisprudence, speaks of only one case having been related; I have not been able to discover any instance of it myself.

It will appear from the foregoing case, that the bi-chromate of potash produces symptoms exactly similar to cholera: such as vomiting, purging, cramp, and great prostration of strength; and as soon as the poison is evacuated from the stomach, must be treated in the same way.—*Prov. Med. and Sur. Jour.*

COLICA PICTONUM FROM THE MEDICINAL EMPLOYMENT OF ACETATE OF LEAD.

By L. S. Joynes, M.D, of Accomack, United States.

The following case is communicated, with the hope that it may prove a useful caution to some of the younger members of the profession, who may be inclined, from over-confidence in the assurances of many of our standard authors, to make too free a use of the potent drug abovementioned. It cannot be doubted that young practitioners in general are too prone to adopt *heroic* methods of practice, and to esteem boldness and decision the chief qualities of a successful physician. Of all the rich fruits which experience brings with it, not the least valuable, certainly, is *caution* in the employment of active remedial agents—all of which, without exception, are potent for evil as well as for good.

It has often appeared to me, that one of the most valuable contributions that could be made to the science of medicine, would be a faithful record of the *real experience* of the profession in the use of the class of remedies just referred to—setting forth the deleterious effects which may be caused by antimony, opium, mercury, lead, &c., as prominently as the good they are capable of accomplishing. Such a record would furnish the most useful lesson of caution in practice that could be given. A desire to contribute to this useful kind of information has influenced me in furnishing the following case for publication; in regard to which, I must admit that the length of time which has elapsed since its occurrence renders my history of it less complete than is desirable, inasmuch as I made no record of it at the time, and am compelled to rely chiefly on memory for the details.

On the 15th of October, 1843, Mr. J. J. B., merchant, aged 25, consulted me on account of a chronic diarrhœa, which had troubled him from time to time for several years, and which had always been obstinate and intractable. He had been treated by different physicians, who had prescribed a great variety of remedies, nearly all of which seemed of little efficacy. After listening to the details of his case, I became satisfied that acetate of lead and opium would prove the most efficient remedy; and as none of his previous medical advisers had prescribed this combination, I determined to give it a trial. I believe I had never before prescribed the acetate of lead, but I relied, very naturally, on the assurances, everywhere to be met with in the books, that the use of the drug is free from risk, provided a perfectly pure article be employed, and acetic acid in some form be prescribed in conjunction with it.

I accordingly selected the most perfect crystals of the acetate, added more than enough of distilled vinegar to neutralize any of the carbonate which might be present as an impurity, then adding the opium, I made the mass into pills. I also directed the patient, immediately after taking each pill, to swallow a teaspoonful of vinegar. The precise formula which I employed, I am unable now to state, but my recollection is distinct, that the entire quantity taken was thirty grains in the course of about four days. The medicine proved most efficient in the relief of the diarrhœa, the discharges being arrested more promptly than by any other remedy, and without any *immediate* ill effects. The patient and myself were both congratulating ourselves upon the favourable result, when one day, perhaps a week after he discontinued the pills, he complained to me of a pain in the epigastrium, radiating to the spine. As the patient was then apparently regaining his health, and in good spirits, I paid little attention to this complaint, supposing it to be a momentary gastralgic affection, occasioned by some imprudence in diet. Not long after I

learned that he was labouring under a severe attack of colic, and I was called on by Dr. Young of this place, his ordinary medical attendant, who came on purpose to ascertain the composition of the pills which the patient had been taking. The peculiar character of the colic with which he was at that time suffering, so strongly resembled those of colica pictonum, that Dr. Young had been led to inquire of him whether he had taken any medicine recently for diarrhœa. There could indeed be little doubt, from the account given me of the symptoms, and the subsequent progress of the case, that the attack was one of saturnine colic of more than ordinary severity.

This attack commenced on the 3rd of November, about a fortnight after the patient had taken the last pill, and continued with occasional slight remissions for eight days, before any decided relief was obtained. The treatment consisted principally of free and oft-repeated doses of calomel and opium, purgatives by the mouth, enemata, and blistering. A very large quantity both of opium and calomel was administered, and every other means employed which an experienced physician could devise, but there was no permanent relief to pain, and no decided action of the bowels, until the eighth day, when the mouth became affected by the mercury. The patient then slowly recovered, but he remained for some time in a very reduced and debilitated condition. It would have been some compensation for all this suffering if he had been permanently cured of his diarrhœa; but no such fortunate result ensued. The attacks continue to recur from time to time, and are as obstinate as ever.

If any should be disposed to doubt whether the above was truly a case of lead colic, in view of the long interval which elapsed between the employment of the remedy and the manifestation of the symptoms, I would remark that this is entirely in accordance with the oft-observed facts in regard to the poisonous operation of lead—slowness of action being the general rule.

This is the only case I have ever met with in my own practice of any serious result following the exhibition of the acetate of lead; indeed, I rarely trifle with the drug now-a-days. But I know of three other cases of the same kind, which have occurred in this neighbourhood. It is fair to add, however, that in at least two of them the remedy was freely used. There is no lack of recorded instances of the sort; but so far as I am informed, cases are very rare in which colic is produced by so small a quantity of the acetate as was administered in the case which I have just related. One such is mentioned by Dr. Burton, in a paper of which extracts are given in *Braithwaite's Retrospect*. Here the patient took fifteen grains in five days, and experienced severe colic; and Professor Trousseau, in his work on Therapeutics, quotes a case in which the patient took six grains of the neutral acetate of lead daily for three successive days; the fourth day a most violent saturnine colic supervened, with jaundice, constipation, retraction of the belly, &c. &c., which only yielded to the "treatment of La Charité," energetically employed. The most remarkable case of all is given by Devergie, in his Méd. Légale:—A student of medicine consulted Professor Fouquier, who prescribed for him some pills containing each one grain of acetate of lead, of which he was directed to take one every day. The *first* pill produced slight colic, the second acted more severely, and the third occasioned such violent symptoms, that some mistake of the apothecary was suspected. The pills were analysed by Devergie, but were found to contain nothing but acetate of lead.

It may be urged, and with truth, that such cases are exceptional, and that they may be explained by the existence of idiosyncrasies in the subjects of them; such as are known to exist with respect to mercury, opium, and other remedies. But allowing this to be true, it must also be admitted that a prudent physician is bound to regard such idiosyncrasies in his practice. The knowledge of their occasional existence should be a warning against the use of hazardous remedies, except under circumstances imperatively calling for their employment.

A circumstance which has doubtless contributed in no small degree to extend the employment of the acetate of lead as a medicine, and to set the minds of physicians at rest in regard to any risk attending it, is the opinion so confidently expressed by Dr. A. T. Thomson that "the carbonate is the only poisonous preparation of lead, and that the acetate can only become so in consequence of its decomposition by the free carbonic acid extricated in the alimentary canal. Hence his precept to direct a draught of vinegar to be taken with each dose of the acetate, in order to prevent such decomposition, as well as (I presume) to resaturate with acetic acid any portion of the carbonate with which the crystals of the acetate may be contaminated.

It requires but little examination of the facts to convince us that this idea is entirely opposed to the well-*teris paribus*, these poisons are active in the direct ratio of known general laws of the action of mineral poisons. *Cœ*-their solubility; and on this general fact is based the theory of antidotes. We give antidotes with the view of converting a soluble preparation of a metal into an insoluble one. Would it not be a singular exception to a general rule, if the acetate, one of the most soluble forms of lead, should be entirely innocuous, and the carbonate, one of the least soluble, alone endowed with poisonous properties? It is true, that small doses of the carbonate would be rendered soluble by the acids of the gastric juice, being converted by them into the chloride and the acetate (assuming, in accordance with the general opinion of chemists, that the hydrochloric or acetic acid, or both, exist in the secretion of the stomach). What then will become of the acetate when swallowed? If it meets with acetic acid in the stomach, it will remain acetate still; if with hydrochloric acid, it will be converted, like the carbonate, into the chloride of lead. The two substances, therefore, when they begin to act on the system, and are absorbed into the blood, will be in precisely the same chemical state. Considering the acid nature of the gastric secretion, and its probable action on all chemical compounds capable of being affected by its ingredients, is not Dr. Thomson's idea of the conversion of acetate of lead into carbonate, by the free carbonic acid in the alimentary canal, evidently a fallacious one? And is not therefore his employment of distilled vinegar in conjunction with the acetate, an illusory protection against the dangers of lead poisoning?

But without further argument on the chemistry of the question, it is sufficient to state that Dr. Thomson's theory is in opposition to the concurrent testimony of the best toxicological authorities of the day, among whom I may cite Orfila, Apjohn, Taylor, Christison and Devergie. The latter writer, whose authority is second to none, distinctly states that the poisonous activity of the compounds of lead is in direct proportion to their solubility. Christison and Taylor both (conclusively, it seems to me) combat the opinion of Thomson. I will quote a few words from the last mentioned of those authors, bearing directly upon the practical point at issue:—"So far as observations on man have yet extended, the carbonate has no more action than the common acetate. Dr. C. G. Mitscherlich has lately proved that the acetate is a poisonous salt, and that when mixed with acetic acid *it is more energetic than when given in the neutral state.* This fact clearly shows that the poisonous effects cannot solely depend on the assumed conversion of the salt to the state of carbonate." (Taylor's Med. Jurisp. 2nd ed., p. 169.

This result of Mitscherlich's researches is precisely what a consideration of the general laws of toxicology would lead us to expect. Let physicians, therefore, take care how they rely on vinegar, or dilute acetic acid, as a *safeguard* against the poisonous effects of the acetate of lead.—*Stethoscope, Virginia, United States.*

Sugar in the Urine.—At a recent meeting of the Academy of Sciences, Paris, M. Regnoso communicated the second part of his researches, in a paper on this subject, in which he showed that the presence of disease in the lungs is attended by the presence of sugar in the urine.

REVIEWS AND NOTICES OF BOOKS.

ON THE PATHOLOGICAL ANATOMY OF BRONCHITIS AND THE DISEASES OF THE LUNG CONNECTED WITH BRONCHIAL OBSTRUCTION.

By W. T. Gairdner, M.D., Fellow of the Royal College of Physicians, and Pathologist to the Royal Infirmary of Edinburgh, Edinburgh. 1850. 8vo. Pamphlet. pp. 82.

Notwithstanding the every day occurrence of bronchitis, notwithstanding its fatality, and the frequency consequently with which we are afforded opportunities for post-mortem examinations, there are some points in its pathology which seem to require further investigation; and although the morbid appearances of bronchitis, and its results, have been described with great accuracy, the mechanism by which some of these results are brought about, does not appear to have been correctly interpreted. Dr. Gairdner's objects in this publication are to elucidate some of these points, and to show that the received doctrines respecting the pathology of bronchitis, admit in some respects of a different interpretation.

The subject is considered under two heads. In the first, "the direct and primary results of bronchitis are discussed; comprising under this head those effects which follow, almost constantly, the accumulation of mucus and inflammatory products in the bronchial tubes, when these are sufficient in quantity to cause serious obstruction." The second includes "the secondary and more permanent disorganizations of the pulmonary texture, which result from the former under peculiar circumstances; being induced either by long-continued intensity of the original disease, or by constitutional states unfavourable to the removal of its results."

"The first part commences some general remarks upon obstruction of the bronchi, which leads to the consideration of "*Collapse of the Lung*, as connected with bronchial obstruction." . . . . . "During the epidemic of continued fever which prevailed in Edinburgh in 1847, it was frequently observed (Dr. Gairdner says) that the lungs, in persons of all ages, were the seat of a form of condensation, characterized by the absence of the friability and granular appearance on section, of pneumonic consolidation, and also by the peculiarity of its microscopic elements, the large granular cells which form so common an ingredient in ordinary red hepatization being either very sparingly or not at all present. The condensed portions were usually scattered over both lungs, and often very limited in extent, being accurately circumscribed by the margins of the lobules."

"The nature of this pulmonary affection appeared to me, at the time, very doubtful. By some it was looked upon as corresponding with the typhoid deposits in the lung, described by German authorities; and the imperfect cell-forms often seen under the microscope seemed to favour this view. On the other hand, careful examination showed that there was frequently little or no real *deposit;* the cell-forms differing very little from those which might be procured from the normal lung; or still better, from one compressed by pleuritic effusion, or other cause. At this time, my experience in pathological studies was not such as to enable me to form a decided opinion; but towards the close of the epidemic, the result of observations inclined me to believe that the lesion so frequently witnessed in fever was not connected with any specific form of morbid deposit, but was, in its purest form, a condition of imperfect expansion or collapse of the pulmonary tissue, similar to that described in the lungs of infants under the name of *atelectasis;* and differing only in its distribution in patches, and in other accessory circumstances, from the condition of *carnification* described by Laennec as the result of compression of the organ."

Dr. Gairdner, after detailing some cases, then gives the following description of the forms of this lesion observed by him:—

"*Bronchitic collapse of the lung* occurs under two distinct aspects—the *diffused* form and the limited or *lobular* form. Of these, the latter variety is the more striking and characteristic, and has been, especially in the lungs of children, the subject of more discussion than the former; but the diffused form is by far the most common, and is, in fact, of very frequent occurrence, at least in its slighter degrees. Both forms present the same fundamental changes of the pulmonary tissue, which is usually of a dark violet colour externally, as seen beneath the pleura; and internally of a more or less deep brownish red, or mahogany tint. The colour, however, is by no means an invariable criterion, depending almost entirely on the amount of blood in the collapsed tissue. The affected parts are always more or less condensed; this condensation may amount to a mere diminution of the crepitation, or to a total absence of it; in which cases, portions are usually found to sink readily in water. These latter portions are both more flaccid and much less friable than the pulmonary tissue when in a state of red hepatization; and they differ greatly from this lesion in the aspect of their section, and the nature of the fluid it yields to the knife. In every variety of true pneumonic consolidation, in which the lung is completely void of air, the air-cells are occupied by a deposit, presenting to the naked eye (and still more distinctly to a power of twenty or thirty diameters) the well known granular aspect of the hepatized lung. If the deposit is fluid or semi-fluid, it is capable of being pressed out or scraped off, in the form of a thick opaque emulsion-like matter, of a yellowish, orange, or gray colour; and in all cases it shows under the microscope abundant granular elements and cell-structures, of the kinds usually found in inflammatory exudations in parenchymatous organs. In the collapsed lung, on the contrary, the section is comparatively smooth, having somewhat the appearance, as described by Laennec, of muscular flesh; it presents no trace of granulations, and yields on pressure, or to the knife, only a semi-transparent bloody serosity, which under the microscope is seen to contain little or nothing besides blood-corpuscles, epithelium, and other portions of normal tissue, and possibly a small amount of pus from the interior of the bronchi.

In the *diffused* variety, the collapsed condition may be found affecting a more or less considerable portion of either or both lungs, usually at their posterior part, and passing quite gradually into normal tissue; the supple, dense, tough feeling being exchanged for the normal spongy, elastic crepitation; and the violet, or deep purple colour, shading off into the usual hue of the surface. Even in this form of the lesion, however, a tendency of it at some points to be circumscribed by the interlobular divisions may often be observed; this tendency being, so far as I have observed, quite characteristic of the bronchitic, as opposed to the pneumonic consolidation.

In the *lobular* forms of bronchitic collapse, which often occupy the anterior edges, as well as all other parts of the lung, the affected portions are every where accurately and abruptly marked off by the interlobular septa, the portions so limited being various in size and form, but always manifestly shrivelled, and sunk in below the level of the surrounding parts. This is peculiarly manifest when they occupy the anterior edges. When they are scattered through the lung, they communicate to the fingers, in feeling the organ externally, much the same sensation as clustered tubercles in the midst of crepitant tissue. This is the form which was so often described as lobular pneumonia in young children, till the experiments of MM. Legendre and Bailly clearly showed it to be nothing but a collapse of the air-cells. These observers were, in fact, the first to apply to this condition of the lung the same test as Jörg had long before used in respect to the congenital atelectasis, and to show that the lung affected with lobular pneumonia could be generally restored to its natural condition by forcible inflation."

The author next devotes a short space to "bronchial abscess;" and the first part concludes with observations and experiments upon "the mechanism, causes, &c., of bronchitic collapse." "In considering, as a whole, the causes which tend to produce bronchitic collapse, they seem (Dr. Gairdner observes) to resolve themselves into the following:—

"1. The existence of mucus in the bronchi, which is more liable to produce obstruction according as it is tenacious and viscid.

2. Weakness or inefficiency of the inspiratory power, however caused.

3. Inability to cough and expectorate, and thus to remove the obstructing mucus.

Of these conditions the first must be considered as the immediate exciting cause, the others as predisposing causes, coöperating with the first, but incapable without it of producing collapse."

The second part of the essay, which is devoted to the secondary results of bronchitis, commences with some remarks upon the "curability of pulmonary collapse," and upon the "de-obstruent function," as the author terms it, of the bronchial tubes. The relation of bronchitic collapse to pulmonary emphysema is next considered; this section contains a table of forty cases of pulmonary emphysema, showing its connexion with other affections, especially of the lungs; in which the age and sex of the patient, the amount, position, and extent of the emphysema, the collateral affections of the lungs or other organs, and the duration and character of the symptoms are given. From this table it appears that in twenty-seven cases, or about sixty-seven per cent., the emphysema was connected with condensation, "presumably bronchitic collapse."

The mechanism of emphysema is next considered at some length. We cannot, however, follow the author through this interesting section of his essay. We shall merely remark that Dr. Gairdner is of opinion "that emphysema of the lung may, in all the cases which he has witnessed, be satisfactorily accounted for by considering it as a *secondary mechanical lesion, dependent on some condition of the respiratory apparatus leading to partially diminished bulk of the pulmonary tissue, and consequently disturbing the balance of air in inspiration.*"

The remaining subjects touched upon in this part are, the "relations of emphysema to hepatization, and tubercle of the lung," and to "excavations and tubercular or bronchial abscesses;" "permanent atrophy of the lung in relation to bronchitis;" "pathological alterations of the bronchi in pulmonary atrophy and in emphysema;" and "pulmonary concretions and cicatrices."

In concluding, we shall merely observe that we have little doubt as to the general correctness of Dr. Gairdner's views; his contribution to the history of bronchitis will well repay the perusal, and it is calculated to add to the author's reputation as an accurate and original observer.

CORRESPONDENCE.

THE RESTRICTION OF GRATUITOUS MEDICAL RELIEF TO POOR PERSONS.

(Extract from a Letter from a Dispensary Governor.)

The editorial article in the Medical Press of the 31st of December last, expatiating so forcibly on the *abuses* under the old dispensary system, and your intention of again returning to the subject, induce me to communicate a few out of the vast number of those abuses which have occurred. . . . . I will begin with a farmer living near this, who, with his family, have received medicines and medical attendance from a dispensary for nearly thirty years. This person has been always in comfortable circumstances, and gave last year a fortune of one hundred pounds with his daughter. About three weeks ago his wife got, as I am led to believe, fever; as usual, he called on the dispensary doctor to visit her, on the strength of his former tickets, who refused going, telling him that according to the rules of the dispensary he never was entitled to benefit from it, as it was established solely for the relief of the poor, and that in future no person could be attended unless such as produced tickets from the relieving officers or the guardians. He seemed astounded, and made application to one of the guardians, who referred him to the relieving officer. The latter told him that he had not as yet the power to give a ticket to any person, but even if he had, he would far outstep his duty by giving one to him; that, in fact, it was out of the question that persons in his circumstances can ever again get relief at a dispensary. He then went to another relieving officer in the district, who told him the same as the former: his response was—"*Well, the world is turned upside down!*" His last resource was to hire a car and bring a *quack doctor*, by which there might have been a saving of a few shillings. I will cite two other cases, on the estates of gentlemen who said peremptorily that they would withdraw their subscriptions (£2 each) unless *all* their tenants, many of them in affluence, had the *full benefit* of the institution. Those gentlemen are non-residents, but they deputed two of the most independent farmers, one of them an under-agent, to dispense tickets. A young man on one of these estates brought a ticket to get a *horseball* for a charger of his, which he was training for a steeple-chase. I need scarcely say that so large a *pill* was refused, although at the risk of having a complaint made to the landlord-subscriber, and at the risk of having his subscription withdrawn. The other person alluded to above, actually gave a ticket to one of his own daughters, who shamefully came with it herself to the dispensary, and of course was attended as an "object of charity," specified in her ticket. . . . . I would beg to offer a *suggestion* with regard to the regulations in contemplation by the commissioners, which is, that unless something is particularly specified as to *visits* to patients, much embarrassment will accrue to the medical officers of the dispensaries, as well as loss of time, and of course risk of life to the patients. For example, it could scarcely be expected that if the doctor went through a great portion of his district in the course of the day, he would be obliged to retrace his steps to see a patient in the evening, or at night, by whose door he passed before; such must be the case, unless he gets the tickets before a certain hour in the morning, always excepting accidents or sudden illness.

EXCESSIVE DISPENSARY DISTRICTS.

TO THE EDITOR OF THE MEDICAL PRESS.

Dear Sir,—Having read the valuable letter of "A Subscriber," in the last number of the Press, in support of his views, I will briefly refer to the dispensary arrangements proposed for an extensive union bordering the Shannon.

For some time past there has not been a dispensary in the entire union; it is now proposed by the guardians to divide it into three districts, with one dispensary in each. So far as humanity and the medical profession are concerned, it would be much better to leave it still without any. The central dispensary district contains a considerable town, with a very large pauper population, from which one extremity of the district is fourteen, and another ten miles, distant; taking the points in a bird-line, but in reality much more, as many large bogs are in it, which must be nearly circumtravelled through all but impassable roads, to arrive at some parts of the district: the two other districts are much larger, and much worse circumstanced.

It is pretty evident it would require a pair of excellent horses in good condition to traverse daily any of these districts, and yet the salary proposed (namely, £60 per annum) would not afford the attendant to keep a donkey.

I have had considerable dispensary practice, and am satisfied from experience that no conscientious man could undertake the duties of a dispensary, such as it is contemplated to be by the recent act, where the extreme points exceed five miles from the centre.

We are all well aware what imposition will be practised on the managing committee to get gratuitous attendance, in midwifery and other cases, by persons comfortably circumstanced. If the commissioners, more particularly our highly esteemed and respected Medical Commissioner, do not interfere, the Medical Charities' Act will become worse than a dead letter—for the medical profession it will be a killing one.—I am, dear sir, &c., A Correspondent.

BAD PAYMENT BAD POLICY.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—When the Medical Charities' Bill was before the Committee of the House of Commons, an amendment was moved to the effect that the boards of guardians should decide on the amount of salary to be paid to the medical officers appointed under the act. This was opposed by Sir William Somerville, who said that if it were left to the guardians they would not give adequate remuneration; but he consented that the boards of guardians should, in the first instance, *propose* what amount they thought fit, subject to the approval of the commissioners, who, if they did not consider the amount sufficient, should have the power of adding to the sum proposed by the guardians. Now, the proceedings of the various boards of guardians in Ireland during the last few weeks, prove how correct Sir William's opinion was. And if he had not reserved to the commissioners the power he did, the whole bill would have proved a total failure; for we hold that no public officer who is inadequately paid can be made to do his duty by any system of inspection or surveillance whatever, for it is obvious that if a public officer cannot live on the salary he receives for doing his duty, he must, of necessity, occupy himself in some additional pursuit, and in proportion as that is remunerative, will his pub-

lic duty become a secondary consideration with him, and be neglected. It is vain to say that this will be corrected by a proper system of inspection. Inspectors may report negligent officers, and commissioners may dismiss them, but their equally badly paid successors will fall, of necessity, into the same course.

It is a common idea among *non*-professional persons, that if a medical officer is badly paid for his public duties, that his appointment is an introduction to private practice, which indirectly remunerates him. This, generally speaking, throughout the country, is a great fallacy; for it is notorious that in every locality one or two favourites of the public monopolize the lion's share of the remunerative practice, while the less favoured medical men are compelled, in order to support themselves and their families, to become farmers, graziers, millers, land agents, or anything else that may offer. And under such circumstances, it is easy to conceive that such men will give as little of their time and attention to the sick poor as they possibly can. This is no fancy sketch, it is drawn from life; and bad as was the old system, the new one will be worse if the salaries now proposed by the boards of guardians should be adopted by commissioners; as, in many instances, to my own knowledge, the salaries voted by these boards are lower than what was paid under the old system, notwithstanding that it is admitted more labour will be required from the medical man, and that he is to act in cases of epidemics of fever, cholera, &c., without any additional fee or reward; and while, in most cases, as far as we can ascertain, these same boards of guardians pay more to their relieving officers than they propose to give the medical officers: the duties of a relieving officer requiring no education beyond what can be obtained in any hedge school. Can it be that these philanthropic and benevolent boards are more solicitous to ascertain whether a pauper is or is not legally chargeable on them, than that the industrious labourer on his sick bed should receive effective medical attendance.

We trust, however, that the matter will not be left altogether in their hands, but that the commissioners will set a higher value on the skilled labour of the physician than on the unskilled labour of the relieving officer, whose valuable services in the eyes of our *Irish* poor-law guardians consists in thrusting as many starving applicants as possible from the doors of the poorhouse. MEDICUS.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JANUARY 14, 1852.

A FEW WORDS TO OUR SUBSCRIBERS.

THE valuable observations of our correspondents, and other matter in this day's publication, relieve us from the duty of dwelling on the working of the Dispensary Act, and leave us at liberty to say a word for ourselves. To the Subscribers to the MEDICAL PRESS, as in duty bound, we have to return our thanks for substantial support; its readers we have to "thank for nothing." We are often amused by the consequential patronizing air with which some of our metropolitan admirers express their approbation of our labours; but we value one Dispensary Doctor on our list more than a score of such hollow adherents. We have often said what we have now to repeat, that this journal is much more the journal of those who support it, than ours, and therefore must it be sustained by those who have sagacity and public spirit enough to see that such an organ is indispensable. If ever the time is to come when the medical profession in Ireland may be left to the protection of the mere mercenary journalist, our services will be better understood than they are, perhaps, at present. That our columns are not to the taste of pompous impostors or illiterate *literati*, we know; and that our style and language is quite shocking to sentimental gentlemen who affect gentility, we are equally certain; but that we, in our own way, effect our object, we are pretty certain; and doing so we care little for the opinion of those who effect nothing. To those who by way of apology for selfishness or parsimony endeavour to undervalue our labours, we would offer a word of advice: let them find some better excuse, or make no excuse at all, and understand that we really do not court their patronage. Let it not be supposed that we are so vain-glorious as to suppose that all are bound to adopt our views or to promote our objects; or, yet again, that all are so circumstanced as to contribute to our undertaking. Far from it. Small as our subscription is, many of our brethren, both in town and country, we are sorry to say, cannot spare it from a limited income, and many worthy members of our profession have so little taste for study that if they received our journal they might not read it. Of such we have no right to complain; neither do we; if we complain of any, it is of those who, for reasons best known to themselves, avail themselves of our labours while they pretend to contemn them. Then we have a word for certain patronizing gentlemen, who now and then seek our good offices, and we hope it will prove *verbum sapienti*. We have no favours to bestow on any but subscribers or such contributors of valuable articles as are as good as subscribers. As we have said, for our brethren of limited means we make every allowance, but for those in good circumstances we make none. But at the same time be it understood that our columns are open even to our opponents if they come in the shape of advocates of a good cause. Their "cases" we may not relish, but their help against the common enemy we may value. By the way, gentlemen who are fonder of their money than of medical journals excuse themselves for not subscribing to ours, by a complaint that we do not give them "cases" enough, or a sufficient supply of "original articles;" but when we contemplate the "cases" and truly "original" articles of some of our contemporaries, we rather feel inclined to congratulate our readers. We consider it a far better plan to give our friends a glimpse of what is passing in the medical world than to overwhelm them beneath a heavy burden of our own manufacture. While we recollect it, we may as well allude to a little reclamation touching our editorial habits. Our worthy contemporary the *Lancet*, who claims to be the medical champion of England, accuses us of robbing him. He says we publish his reports of the proceedings of the London Societies without acknowledgment, which in the first place we deny; for we have as often quoted from his defunct rival, the *Medical Gazette*, as from him; and in the second, if we have done so, we have only done what all newspapers out of London practise with respect to the metropolitan press. But the truth is, we venture to do what other journals do not. We quote freely and acknowledge frankly, regardless of the policy which warns cautious journalists not to quote from rivals, lest thereby they might contribute to their circulation.

THE MARCH OF MEDICAL INTELLECT.

At length people begin to doubt the "wisdom of our ancestors," or at least to think that Queen Elizabeth and James the First were not in a state of mind well adapted to medical legislation, when the one assigned to the shopkeepers of Edinburgh the duty of regulating medical education, and the other to eight learned divines of Trinity College, Dublin, the office of fashioning "matriculated medical students" into surgical shams. It is a curious result, however, which this state of affairs exhibits, and an instructive one. It is not, after all, the royal enemy of witches and tobacco, or the vigorous Virgin Queen, who sways our destinies through these creations of their fancy, but much more substantial influences. The lecturing interest is evidently the moving power in both cases, and certificate money the inspiring agent. From the following we gather that the extra-murals of Edinburgh are quite as much the motive power as the intra-murals of Dublin :—

On the 16th of December last, the Town Council of the city of Edinburgh held a meeting, at which the memorial of Professor Syme, calling upon the patrons to dismiss Professor Henderson from the Chair of Pathology, was taken into consideration. Speeches were made by the Lord Provost and Baillie Brown—the one to the effect that the Town Council could not, and the other that they ought not to, interfere with Professor Henderson as long as he continued to teach the doctrines of pathology from his chair. The conclusion arrived at was, that the memorial should be referred to the college committee, which is equivalent to passing to the order of the day. The Town Council did not, however, leave Professor Syme without pointing out a method by which the obnoxious professor might be starved out of his position. It appears that the patrons of the university—that is, the Town Council—claim the power of arranging the curriculum for students who intend to graduate; and in 1847 they enacted a new set of statutes respecting the medical degree, by virtue of which no student would have been under the necessity of attending any particular professor, whose course of instruction was distasteful to him, but would have been able to have left such a teacher for a lecturer beyond the limits of the university. But the professors of the university considered this an attack upon their privileges, and disputed the right of the Town Council to regulate the educational classes, bringing an action against the Town Council, on this point, in the Court of Session. In this court, a decision was recently given against the professors, who appealed to the House of Peers; and years may now elapse before any binding decision is pronounced. In the Town Council meeting of last week, the speakers dwelt much upon this subject. It appears the Town Council wishes that one-third of the lectures necessary for graduation should, if students so desire it, be taken at the extra-mural schools of Edinburgh. The Lord Provost concluded by saying that—"He was of opinion the professors ought to make some concession; and if they were to do so, by proposing, say to accept a fourth, instead of a third, of the prescribed course of medical study, without the walls of the university, in the matter of qualifying for medical degrees, he was certain that the council would be prepared to meet them in a friendly spirit. He was in hopes that an arrangement might yet be made on some such reasonable footing, and thus put an end to the unseemly contest now going on between the Town Council and the Senatus Academicus." It is indeed "unseemly" that the patrons of a university should be at war with the professors they have themselves appointed. But we are by no means sure that the proposal of the Town Council is not a good one. At present the system of recognized lecturing partakes of the nature of monopoly. There is nothing like a little competition in rendering all things human as perfect as possible. It is evident that the Town Council will not comply with the wishes of the professors; indeed, they seem rather pleased at being supplied with so good an argument in favour of their own scheme, an advantage which they are not likely to forego. We sincerely think the best thing, in the actual condition of affairs, would be to accept the proposal of the patrons, perhaps with some further modification. The professors would lose much less by such a regulation than by the retention of the present system and such lecturers as Professor Henderson and Professor Gregory. The globulist professor aims evidently at the character of a "complete letter-writer." We have noticed several of his published lucubrations of this sort during the present year, and he has just visited the Edinburgh public with another "letter," addressed to the patrons of the university, and referring to the memorial of Professor Syme. It is verbose enough, with several most sorry attempts at the jocular, in which the globulist is anything but successful. In the whole of his eleven pages we find but one fact worth noticing, which is, that in the year 1851, out of the large number of students attending the university, there were only sixteen in attendance upon his class of pathology, besides those who were obliged to attend in order to obtain the degree of M.D. Only sixteen voluntary pupils out of the whole university! We should have thought this fact damning enough; but the globulist congratulates himself upon it. He plainly says, he "would far rather see the school without a pupil" than be himself expelled. It seems clear that the globulist professor must be removed, unless the university is content to see its highest and most honourable privilege—that of conferring degrees and sending forth scions to increase and sustain the reputation of their Alma Mater—grow less and less every year. It seems the Town Council will not expel him. It only remains, therefore, for the Faculty of Medicine to accept students for graduation without lectures on pathology, if that can be done; or to make the best terms they can with the Town Council. The mischief which must accrue to the university should Professor Henderson remain during the next seven years, as he has remained during the past, is incalculable, and far beyond, in our opinion, any injury which could arise from the recognition of a limited number of lectures by extra-academical teachers.—*Lancet.*

APOTHECARIES TO DISPENSARIES.

The following extract from a report of the proceedings of the North Dublin Union will remind the Dispensary Surgeons of a matter which concerns them nearly. They will, we conclude, recollect that arrangements suited to large towns, or made to answer local purposes, may not be safe elsewhere. The Guardians of the South Dublin Union have resolved to appoint apothecaries at salaries of £60 :—

The Clerk read a circular from the Poor-law Commissioners, which contained the following passage :—

"In regard to the arrangements for the North City District, I am to state that the commissioners presume that the guardians contemplate that apothecaries should be appointed as part of the officers for the service of that district; and the commissioners have accordingly made provision in article 4 of the order for their appointment, in pursuance of the 6th section of the act. The commissioners are not informed of the salaries which the guardians propose for these officers, and request to be furnished with their views on the subject."

The following resolution was moved by Mr. Long :—

"Resolved—That the commissioners labour under a great mistake in presuming that the guardians intended to have apothecaries in the North City District. That in fixing the salaries of the medical officers to be appointed therein at £75 a year, they considered it fair remuneration for the entire services to be rendered, including the compounding of medicine; and that if the commissioners persist in having apothecaries appointed, the guardians will either have to reduce the above sum of £75 to the medical officer, or vote a mere nominal remuneration to the apothecaries contemplated by the commissioners' order."

Mr. Long said the guardians did not contemplate that there should be apothecaries in the city districts, or they would not have fixed the salaries of those men at £75 per annum. He did not see the necessity of appointing apothecaries in the city districts, when they were to have none for the county (hear). In his opinion it was best to inform the commissioners at once that the guardians, in coming to the conclusion of appointing six medical men in the city districts, understood they were not to have apothecaries. If they were to be appointed, it would become necessary for them to reconsider the salaries to be given to the medical officers.

Mr. Arkins thought that they could never expect their medical men to compound medicines; they had never served

their time to any apothecary, and it would be a degradation to them.

Mr. Roper said that medical men in England frequently compounded their medicines. If the board were to appoint apothecaries they would be plagued with elections, patronage, and jobbing (hear, hear).

Mr. Hardy totally negatived the idea that they were to appoint apothecaries along with physicians.

The Chairman said he had occasion to employ a medical gentleman, when in England, who compounded his own medicines. That gentleman was in high repute, being in attendance upon the Queen's children.

Dr. Hill, inspector, observed that most of the guardians who had addressed the meeting on the subject seemed to have taken it for granted that the commissioners had referred to the subject of appointing apothecaries because they thought it derogatory to medical officers to compound their own medicines. That was not the view of the commissioners; and he thought there was nothing in their communication that would lead to such a supposition. It appeared that the reason why they spoke of apothecaries was, because they thought it probable that the duties which would devolve on the medical officers would be greater than they could discharge efficiently. It was not contemplated that the compounding would be derogatory to the medical officer, but it was thought that the apothecaries would relieve them from a part of their duties.

The resolution having been seconded by Mr. Roper, was put from the chair, and passed unanimously.

"Dr. Phelan, who has been for some years inspecting workhouses chiefly in reference to their sanitary condition, has now ceased to perform that duty, and has been placed in charge of the Londonderry and surrounding unions, as an ordinary poor-law inspector."—*Freeman's Journal.*

Although we cannot perhaps congratulate our brethren of the Londonderry and surrounding unions upon this translation, we can the exemplary functionary who is the subject of it. For some seventeen years or so he has devoted his services without interruption or relaxation to the invidious task of instructing the Hospital Surgeons as to their duties, and now we rejoice to see him relieved from his vexations. *Requiescat in pace.*

APOTHECARIES' WEIGHT.

We copy the following from a London contemporary, but we know not what it means. No "poor-law doctors" contract for medicine in this country. We conclude that some communication on the subject has been misunderstood, and hence this blunder. The "Gentlemen of the Hall" are very anxious to have "a finger in the pie;" but the vending of medicines and the vending of sham diplomas so badly agree, that their overtures have hitherto proved abortive:—

The Regulated Weight of Medicine.—The Apothecaries' Hall of Dublin, in reply to an application upon the subject, have declared that poor-law union doctors contracting for medicine as well as advice, must give twelve ounces to the pound.

A BRAZEN HOMŒOPATH.

To the President of the Royal College of Physicians, London.

Sir,—I am anxious to know if you will admit me to examination for the degree of Doctor of Medicine, and as I wish to act honestly and fairly to you, I think it best to state, that I differ from the views of the college in one branch of the examination—viz., the therapeutical. However, I will give my answer to any question you put according to the old mode of healing disease, and at the same time, if agreeable to you, state what homœopathists consider the best method of curing disease. I trust the fact of my being a homœopathist, which I am from conviction and long experience, will not prevent you from granting me that diploma which I am desirous of obtaining.—I have the honour to be, &c. &c.

Reply.

Sir,—The foundation of the Royal College of Physicians was for the purpose of guaranteeing to the public skilful and safe practitioners. The College of Physicians regard the so-called homœopathists as neither skilful nor safe practitioners. Therefore the college cannot, without betraying a sacred trust, give its licence to persons whom they regard as wholly unworthy their confidence, and with whom it is not possible they can hold any communion.—I remain, sir, your obedient servant, J. A. Paris.

EXAMINATION PAPERS OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON.

First Examination.—In Parte Physiologica.—1. Describe the structure of the liver. Give your opinion as to the process by which bile is formed, and the uses of that fluid in the animal economy.

2. Mention the attachments of the diaphragm, its actions and uses. Name the openings by which communication is effected between the cavities of the abdomen and thorax, and the organs which pass through them.

3. Enumerate the principal mucous and serous membranes of the body. Where do these tissues come in contact? By what circumstances of structure and of function can they be distinguished?

4. Enumerate the arteries which form the circle of Willis, and mention any peculiarities which characterize the circulation within the cranium.

5. What are the proximate principles of the blood? In what respect does venous differ from arterial blood? By what means is it converted into it?

Second Examination.—In Parte Pathologica.—1. Describe a case of traumatic tetanus in its ordinary progress from the local injury in which it originates, to its termination by death or in recovery.

2. Give an account of the eruptive fever known among physicians as idiopathic erysipelas of the head and face.

3. What is strangulated hernia? What are its varieties? How is it expressed by symptoms? and, if unrelieved, how does it kill?

4. What are the symptoms induced by certain noxious varieties of the field-mushroom? Compare and contrast them with the effects, by poisoning, of oxalic acid.

5. What are the evidences, local and constitutional, of retained placenta, at intervals of three days and of three weeks, respectively, from the period of delivery?

6. Enumerate the principal results of change in the composition of the blood coincident in the system with fever, gout, or granular disease of the kidney.

Third Examination.—In Parte Therapeutica.—1. State the effect of general bleeding on the composition of the blood; the objects attempted to be fulfilled by it in the treatment of inflammatory diseases; and the cautions to be observed in its use.

2. State what is known of the physiological action of opium; the conditions in which it can be given with advantage in unusually large doses; and some of those in which only small doses, if any, are expedient or safe.

3. Mention the different means employed to arrest hæmoptysis; and the circumstances in which they are respectively useful.

4. Name the medicines which are considered to have an especial action in subduing catarrh of the bladder; the classes to which they severally belong; the preparations of them in the London Pharmacopœia, and their doses.

5. Mention the different salts of potash and soda used in medicine; their chemical composition, physiological action, and doses.

6. Describe the process for preparing quinæ disulphas.

December, 1851.

ASSOCIATION OF MEDICAL ATTENDANTS OF FEVER HOSPITALS AND DISPENSARIES IN IRELAND.

The office of Honorary Secretary, vacant by the promotion of Dr. Knox, has been kindly accepted by Dr. Waters of Parsonstown, to whom all communications on the subject of the medical charities are requested to be made.

Wm. Kingsley,
Chairman of the Standing Committee.

Obituary.—At Cootehill, on the 28th ult., John Horan, Esq., M.D.

M. W. HANLON, M.B.

ACCUSATION OF MALA-PRAXIS IN FRANCE.—A case was lately tried at Monthrison, in France, which shows how unjustly the friends of a patient may burden the medical attendant with the untoward results of his treatment. Dr. Poyet was charged by the widow of man who had died after fracture of the femur—1, with refusing to call in another surgeon; 2, with having announced consolidation during the treatment; 3, with not having acquainted the family with the serious nature of the case. Dr. Poyet, however, brought sufficient evidence to show that the fracture was very oblique, and that the want of success was entirely owing to the negligence of the patient's friends. He obtained a verdict in his favour, £12 for his attendance, and the plaintiff was charged with the costs.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT
is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

THE REVERSED AND DOUBLE-ACTIONED PATENT TRUSS.

Invented by FRANCIS L'ESTRANGE, Esq., F R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the medical profession and the public to this Truss. He can state with confidence it is the only instrument constructed on scientific principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

THE ROYAL EXCHANGE ASSURANCE,

Incorporated A.D. 1720, by Charter of George the First.

THOMAS TROUTON, AGENT,

No. 8, WESTMORLAND-STREET, DUBLIN.

Fire and Marine Assurances on liberal terms.

Life Assurances with Bonus (which has averaged 43 *per cent.* on the Premium); or, at lower rates, without Bonus.

Moderate Premiums and a fair division of Surplus.

Age.	With Profit. £ s. d.	Age.	Without Profit. £ s. d.

Exemption by the Charter from the liabilities of Partnership.

The Security of a large Capital Stock, and the moral guarantee afforded by 131 years' experience and reputation.

The soundness of a thoroughly tested Office, with all the real improvements of modern practice.

THOMAS TROUTON, AGENT,
(Successor to Richard Purdy,)
No. 8, WESTMORLAND-STREET, DUBLIN.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

AN elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

Extracts and Editorial Note from the New York Journal of Medicine.

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,
"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,
"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

Just published, 8vo, pp. 96, price 2s. 6d.,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By Arthur Jacob, M.D., F R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the Medical Press, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By William Henry Porter, M.D.,
Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on Venereal Diseases, with additional Notes and Illustrations.

DR. BELLINGHAM ON ANEURISM.

Lately published, 12mo, price 4s.,

OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.

By O'B. Bellingham, F.R.C.S.I.,
One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chir. Rev.*

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet.*

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences.*

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review.*

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author.*

London: John Churchill, Princes-street, Soho.
Dublin: Fannin and Co., Grafton-street.

On the 1st of January, post 8vo, cloth, 6s. 6d., Vol. XIV.,

HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES.

Edited by W. H. Ranking, M.D., Cantab.,
Physician to the Norfolk and Norwich Hospital.

"This is one of the most valuable medical publications of the times."—*North-Western Surgical Journal.*

For the accommodation of New Subscribers, Complete Sets, Vols. I. to XII., may be had at the reduced price of £3 3s.

London: John Churchill, Princes-street, Soho.

Ferri Acet. P.D.—Precaution in prescribing Strong Doses—Sheep-Dipping Composition—Huggins *v.* Froom, &c. &c. Price 1s.

London: John Churchill, Princes-street, Leicester-square; Maclachlan and Stewart, Edinburgh; and Fannin and Co., Dublin.

*** Volume X. may be had in boards, as well as the preceding volumes, price 12s. 6d. each.

BRAITHWAITE'S RETROSPECT OF MEDICINE.

Just published, price 6s., Volume Twenty-four of this work,

Giving a careful Analysis of the most Practical Papers, Lectures, and Transactions of Societies, published in all the Medical Journals within the last Six Months. Appended to which is an Alphabetical List of Diseases; with the most recent Suggestions of Treatment.

Edited by W. Braithwaite, Lecturer on Obstetric Medicine in the Leeds School of Medicine, &c.

*** This Volume contains a General Index to Vols. 21, 22, 23, and 24.

London: Simpkin, Marshall, and Co.; Edinburgh: Oliver and Boyd; Dublin: Hodges and Smith.

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the Insane, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. Jacob,
Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

This Establishment, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A.

(Continued from page 421, vol. xxvi.)

"Nutrition."

(Concluded.)

(The Appropriation of Fibrin.)

In my last communication, we were engaged in the two-fold inquiry—namely, 1st, as to the agency or instrumentality *whereby* the fibrin of the human blood is generated from albumen; and 2nd, as to the position or locus in the mechanism of man *wherein* such generation normally takes place. In relation to those inquiries, it has there been my effort to make apparent—1st, that the *sole* agency or instrumentality whereby albumen can, by possibility, be converted into fibrin, is *an organizing agent* provided for that purpose by Nature; and 2nd, that the part of the human mechanism wherein (in its normal condition) such conversion or generation takes place, is the *interior* of the vascular system. The questions which are now about to engage our attention are the following—namely, *how* and *where* (when its generation *within* the parietes of the vascular system has been completed) is that fibrin appropriated to the purposes of nutrition? For the purpose of illustrating the reply to the two divisions of this question—namely, as to the *manner* and the *place* of the appropriation of fibrin to the demands or requirements of man, I shall, as I have already observed, select *muscular fibre*. In making this selection, I would again remind my readers that *the general principles* upon which have been arranged the *generation and decay* of *all* the various organized structures whose functions respectively are to give development to what we term "the phenomena of *animal* life," that the general arrangements, I say, for their generation and decay have been for each and for all of those structures the same; and, consequently, in investigating the nature of what is termed "*the process of nutrition*," and the process of *degeneration*, in their relation to any *one* of those structures, we have investigated the nature of these processes in their relation to *all*.

The first thing, then, we have to do in relation to the present inquiry is, to search for one of those organizing agents which by Nature has been endowed with the faculty of converting fibrin into muscular fibre, and having found such, to observe how and where that conversion takes place. We have, in a word, but to select *a solitary muscular atom*, and to contemplate that atom, *in situ*, while in the discharge of its physiological function; and in such contemplation we shall obtain a reply to the two divisions of our present inquiry, and consequently, at the same time, a clear, a comprehensive, and an accurate acquaintance with the true nature of what is termed "*the nutritive process*," as that process takes place in all the various components of man. Where, then, or in what part of the human mechanism, has that organizing agent been placed? Where, in a word, are we to search for the muscular atom? This question admits of a simple reply. We must search for it wherever there exists *muscular fibre*. Where, then, or in what part of the human mechanism has muscular fibre been placed? or, in other words, what is the position of muscular fibre *in its relation to the parietes of the vascular system?* It is, and there is no one will question this fact, it is placed *externally* to the vascular parietes; it is situated at *the external surface* of the parietes of the vascular system. Such, it will not be questioned, *is* the position of *muscular fibre*; and, consequently, such *must be* the position of *the agent* by which that muscular fibre has been generated. Externally, I say, and alone externally, to the vascular parietes, is muscular fibre found to exist; consequently, externally and alone externally to those parietes can the generation of that fibre have taken place; and, consequently, *externally and alone externally to the parietes of the vascular system must be the position of the muscular atom*. The same is equally true with regard to the various other *organized residual products* (as also with regard to the *organizing agents* by which such other products have been generated) which give development to the

various other phenomena named "the phenomena of animal life."

What, then, have we learned as regards the relative position of the muscular atom (as also of the cerebral, the nervous, the glandular, &c., atoms), what, I say, have we learned as regards the relative position in the human mechanism of the muscular atom and its specific stimulus or nutriment—namely fibrin? We have learned this: we have learned that these two entities *are separated from each other by the parietes of the vascular system*; we have learned that the *specific stimulus* or nutriment—namely, the fibrinous residual product, is placed at the *internal* surface of the vascular parietes, while the *organizing agent* which that residual product has been adapted by Nature for arousing or stimulating to the discharge of its specific physiological function, has been placed at the *external* surface of those parietes.*

How, then, does fibrin come in contact with the muscular atom? How, in a word, does it *escape from* the parietes of the vascular system? In a manner identically analogous to that in which we have seen albumen to *enter* that system; by that force of attaction which we have already seen to exist between the muscular atom and fibrin—namely, that attraction which Nature has placed between every organizing agent and its specific stimulus (analogous, as I have attempted to point out, to the attraction existing between an acid and a base), by the force of attraction, I say, existing between the muscular atom and fibrin, the latter—namely, fibrin—placed in the *interior* of the vascular system, and existing there in the form of a *fluid*; this latter, I say, or fibrin, by the force of that attraction *must be drawn to the external surface of the vascular parietes*, inasmuch as the former or muscular atom from its *granular* constitution would be *physically incapable* of passing in the opposite direction. Thus, then, we see the agency or means whereby the liquor sanguinis of the blood is extravasated beyond the vascular parietes into the *extravascular interstices*. Having arrived at the *external* surface of the vascular parietes, how *then* is the fibrin disposed of? It is thus. It *there* meets with the muscular atom (as also with the cerebral, nervous, glandular, &c., atoms), which it at once arouses or stimulates to the discharge of its specific physiological function of conferring (increased) organization. The muscular atom now presented with its specific stimulus or nutriment, radiates thereon its own influence centrifugally and in every direction, thereby surrounding itself with an envelope of fibrin—raises that fibrin still higher in the scale of organization; that is, converts it, though already highly organized, into matter possessed of a still higher degree of organization, which matter it eventually disposes of thus—namely, 1st, it regenerates a plurality of the muscular atom, which atoms are competent, *whenever the general organism man may have a demand for their function* (I would solicit my readers' attention to the words in *italics*†), it regenerates, I say, 1st, a plurality of muscular atoms which are competent, *when required*, to generate a new muscular fibre; and 2nd, it generates an organized residual product named *muscular fibre*, designed to perform the specific physiological function *(peculiar to itself)*; to which we give the name "*muscular contraction*." Such is the entire function of the muscular atom, and in the discharge of such function, that atom has *itself* been reduced to the condition, *of unorganized matter*; in a word, when its function has been completed, that atom has become a portion of the mineral world, has become *dead* or *inanimate* matter. The reader will please to observe that it is *an organizing agent* (viz., the muscular *atom*), and not *an organized residual product* (such as muscular *fibre*), which has during that process been reduced to the condition of unorganized or mineral matter.

Such is the manner in which muscular fibre is *generated* (mark the word *generated*, for we shall presently see the same muscular fibre *de*-generated, that is, undergoing the process of *disorganization or degeneration*), such, I say, is the manner in which muscular fibre is generated; and before proceeding further with the consideration of that fibre, I would venture to solicit my readers to run over in imagination *the entire* of this process, from the organizing of unorganized or mineral matter to the conversion of that same mineral matter into muscular fibre. And why, I may be asked, *here* solicit thus of my readers? Simply for this reason, that *here* commences a new, and altogether distinct, topic of inquiry; a new and altogether distinct class of organic phenomena—namely, the *de*-generation or *degradation* in the scale of organization of *an organized residual product* (mark, of *an organized residual product* in contradistinction to an *organizing agent*). Hitherto we have been contemplating the *generation* of organized residual products—namely, the *elevation* of such products, by progressive steps, in the scale of organization. We now, *for the first time*, have to contemplate the *degeneration* of an organized residual product—namely, the *depression* or *degeneration* of such products in the scale of organization, and consequently have to contemplate an altogether new and distinct class of phenomena.

Hitherto we have been contemplating the process of generation or reproduction, but with the generation of muscular fibre and the like, we *have done* with that process. With the generation of that fibre, and of structures of its kind, we *have done* with what is termed "*the process of nutrition*." We have done with the phenomena of organic or vegetative life; in a word, we have done with the *elevation* of matter in the scale of organization, and consequently we have done with the process of organic or vegetative "*living*." *That* process (for the foregoing are all but one and the same physiological process under dif-

* We have here suggested to us what *must have been* the relative position of the various atoms in the *embryo* or *germ* of man—namely, a *vascular atom* must have been placed in that germ *intermediately between a fibrinous and a muscular, &c., atom*. By an application of the same principle of inquiry to all the various organized structures which enter into the constitution of man, we can arrive at a knowledge of *the anatomic arrangement of the various components of the germ or embryo of man*, notwithstanding that embryo is *microscopic*.

† I have requested my readers' attention in the above paragraph to the words "*whenever the organism shall have a demand for its function*," inasmuch as, to me, it appears to be a physiological question of no inconsiderable importance to ascertain what provision Nature has made *for the fulfilment* of that demand. *By what arrangement*, in other words, has it been provided by Nature that a *new supply* of fibrin *in exactly the required quantity* (that is, neither deficient nor in excess), and at *exactly the required moment*, should be conveyed within the sphere of the attraction of the offspring atom, that is, to the contiguous capillaries, when the general organism has a demand for the function of that atom. Let me be distinctly understood. It must be obvious that the offspring muscular atom *does not* (under normal circumstances) commence the discharge of its function (namely, of generating a *new* muscular fibre) until the function of the *first formed* muscular fibre has in the first place commenced; for otherwise there would be obviously an undue amount of muscular fibre in the organism, which (though *pathologically* it does occur) can never take place *physiologically*. *How* has that been arranged? I shall, in order to illustrate my meaning, apply the same inquiry to the fibrinous atom. By what provision of Nature has it been arranged that the *fibrinous atom* (situated *within* the vascular parietes) should, at *the required time* and *in the required amount*, be supplied with *its* specific stimulus or "nutriment"—namely, albumen? By what provision or arrangement, I say, has this been accomplished? By a *most complex physiological provision*—namely, by what is termed *the sensation of hunger*. And surely my readers will scarcely suppose that the atoms placed externally to the vascular parietes have been wholly overlooked in such arrangement—have been left altogether without some analogous provision. *What is that provision?* It is for physiologists to determine that question. The present would not be the most appropriate place to express my own opinions upon that subject; but I have considered it desirable here to direct the reader's attention to the question, lest it might appear that in my observations upon what is termed "the nutritive process," I had overlooked what I regard as a *most important* physiological inquiry.

ferent names), that process, I say, my readers have seen performed in a manner *identically the same* throughout the *vegetable* and the *animal* world. Of that process we now for the present take leave to inquire what becomes of the *final* results of that process.

Here, then—that is, when the generation of muscular fibre, &c., has been completed—*here*, I say, commences with the *function* of that muscular fibre a new and altogether distinct class of organic phenomena, giving development to a new and altogether distinct class of results—namely, to those results termed "the phenomena of *animal* life." Let us, then, contemplate the development of such phenomena, and observe *how that development effects the constitution of muscular fibre, &c.* The general organism (man) has a demand for the operation of the specific physiological function of muscular fibre; that is, in other words, has occasion for muscular motion; which muscular motion is a phenomenon peculiar to *animal* life. But the discharge of this function (namely, muscular motion) *of necessity de*-generates or, in other words, *degrades* in the scale of organization that muscular fibre, so as altogether to incapacitate it from again performing a similar function. If, then, the general organism (man) has a *second time* a demand for the operation of muscular fibre, what must be the result? The result must be obviously this—namely, that one of the *offspring* atoms, which we have recently seen generated, must be called to the discharge of its physiological function. An offspring atom, I say, must be called on, *again* to raise matter in the scale of organization; *again* to confer increased organization on fibrin. In a word, must be called on *to generate a new muscular fibre*. Hence the necessity for the renewal of the regenerative process; hence the necessity for the *repetition* of what is termed "*the process of nutrition.*"*

Let us now reflect for a moment upon the two processes we have just been contemplating—namely, that of the *generation* and of the *de*-generation of muscular fibre. We have attempted to trace unorganized or mineral matter from the inanimate world in its passage through the two departments of organic creation; we have seen that by successive acts *of generation* that matter has eventually been converted into muscular fibre; we have seen that during its passage through the vegetable and the animal kingdom, such matter has been converted into different

* The contemplation of these two processes (namely, that termed *nutrition* and the process of *degeneration*), as I have attempted to detail them above, may perhaps suggest to some of my readers the following inquiry—namely, why is it that muscular fibre (&c.) requires to be *degenerated*, so as to render essential its renovation or renewal? What necessity can there be for the *re*-generation (viz., nutrition) of an organized structure, such as muscular fibre, after that structure has once been generated in man? wherefore is it that the *same* muscular fibre (&c.), when once it has been formed, cannot discharge its required physiological function *continuously during the entire period* that man has occasion for the contraction of muscular fibre, &c.? why, in a word, must such organized structures, when the process of their generation has been completed, be degenerated or undergo the process of disorganization, so as to give occasion for their *re*-generation or *nutrition*? This is a most important as well as solemn physiological inquiry, involving in its investigation the consideration of the two following questions—namely, 1st, what is the nature of the distinction between the vegetable and the animal? and 2nd, what is the nature of the connexion which exists between *life* and *death*? What is it which *constitutes death*? I shall presently attempt to reply to these questions.

The general answer to the foregoing inquiry (namely, as to *the necessity* for the process of disorganization or *de*-generation) is this—namely, organic or living creation has so been arranged or construted by Nature that *the act* of giving development or manifestation to what are termed "*vital phenomena*" in general, has been inseparably associated with, and made indispensably dependent upon, *the depression or degradation of matter in the scale of organization*. In a word, paradoxical as such statement may perhaps to some of my readers appear, the phenomena of *life* have been made *indispensably dependent* upon the phenomena of *death*. The nature of this dependency I shall shortly endeavour to point out to the reader.

It is in accordance with this general arrangement or provision of Nature (the existence of which admits of no question) that every organized structure occupying a physiological position in the *animal* kingdom analogous to that of muscular fibre, must, *while in the act of* discharging its specific physiological function, be at the same time undergoing the process of disorganization or degradation; must at the same time be *in the act* of losing or parting with that condition which constituted it an *organized structure*. Paradoxical, then, I say, as such statement may appear to those who may never have reflected on the subject, at the moment that an organized structure is giving development to what are termed the "phenomena of *animal* life," at such moment that structure is *descending* in the scale of organization; is resigning or parting with its organic or physiological properties; is approaching the condition of dead or inanimate matter; in a word, *is undergoing the process of dying*. If, then, during the period of the development of the phenomena of animal life—namely, of mental phenomena, nervous phenomena, and the phenomena of muscular motion, if, I say, *during the period of their development*, the organized structures, which are the source or origin of such phenomena, be themselves at that moment approaching the condition of dead or inanimate matter; be resigning or parting with their organic or physiological properties, and consequently be thereby becoming *utterly incapacitated* from *again* giving development to the phenomena in question; if, I say, such be the case (and that such *is* the case admits of no question), it is obvious that should it be required, that mental phenomena, nervous phenomena, or the phenomena of muscular motion, should be *continuously* developed in man; it is, I say, obvious that in order to accomplish that end, the organized structures which develope or give manifestation to such phenomena (that is, cerebral matter, nervous tissues, and muscular fibre) must themseves be undergoing the process of *continual renewal*. Hence we can understand *why it is* that in order to continue to be a living being, man must *continuously* be furnished with food.

The *physiological principle* upon which is *dependent* the necessity for *the depression or degradation of matter in the scale of organization* (or what, for perspicuity, I have termed *the process of dying*) synchronously with the development or manifestation of what we term "vital phenomena;" the physiological *principle*, I say, upon which the necessity for such de-generation is *dependent*, though appearing to me to admit not only of an intelligible but of a simple explanation could not, as I regard it, be *here* advantageously canvassed. An attempt at a full and clear exposition of that principle, though not as I have observed involving in it (as I conceive) any peculiar physiological difficulty, would, notwithstanding, occupy considerable space; which space (from the *fact* that such *has been* Nature's arrangement admitting no question) I should not consider it advantageous at present to devote to that subject. Without, then, at present attempting to investigate that principle, that is, without stopping to inquire *why* (consistently with the existing state of things) such *must of necessity have been* Nature's arrangement, I shall now proceed to attempt to point out somewhat more clearly to the reader what I conceive to be *the nature* of the connexion that exists between *life* and *death*, and shall endeavour to convince him that the phenomena of living *in general* (including those of vegetable and animal life) *have been* made indispensably *dependent* upon the phenomena of organic degeneration or *dying*.

There are but four circumstances or conditions under which it is possible to contemplate matter in its relation to what we term organization and life; that is, in other words, matter in its relation to what is termed organization and life, must be contemplated while in one of the four following conditions—namely, such matter may be contemplated, 1st, in its unorganized or mineral condition, that is, totally and altogether devoid of organization or life, in a word, it may be contemplated as *dead or inanimate matter*; 2nd, such matter may be contemplated while in the act of receiving organization and life; that is, while in the act of passing either from the condition of dead or inanimate matter to the condition which constitutes it organized, or from the condition of organized matter to the condition of matter possessed of a higher degree of organization, in a word, it may be contemplated while *in the act of being elevated in the scale of organization*. To matter so circumstanced, I have for perspicuity ventured

species of *organized residual products*, such as those we call albumen and fibrin; and we have seen that each succeeding residual product had conferred upon it a *higher degree* of organization than the preceding residual product had possessed. But mark this well, *in no instance* during the passage of that matter through the vegetable and the animal kingdom have we seen the *de*-generation of *an organized residual product*. In no instance, I say, during the process of generation or "nutrition" have we seen *an organized residual product* depressed or degraded in the scale of organization. It was not till the process of generation or "nutrition" had been *completed* that the *de*-generation of *an organized residual product* commenced; it was not till the *final* result of "nutrition" had been formed that *an organized residual product* began to *descend in the scale of organization*. In a word, it was not till an organized residual product was called on to develope "the phenomena of *animal* life" that the disorganization or degeneration of *an organized residual product* commenced. And what do we collect from this fact?

---

to restrict the term "*living*," in order to enable me more clearly to point out to the reader the nature of the *dependency* of *life* upon *death;* 3rd, such matter may be contemplated when possessed of organization and life, but existing in a quiescent or inactive condition; that is, while manifesting no active phenomena which distinguish it from dead or inanimate matter, as, for example, in the condition of the seed of a vegetable before germination has commenced; matter so circumstanced, I would for perspicuity term *matter possessed of quiescent vitality;* and 4th, and lastly, such matter may be contemplated while in the act of resigning or parting with organization and life; that is, while in the act of descending either from the condition of organized to that of inorganic or mineral matter, or from the condition of matter possessed of a higher to that of matter possessed of a lower degree of organization; in a word, it may be contemplated while *in the act of being degraded in the scale of organization*. To matter so circumstanced I would, for perspicuity, venture to apply the term *dying* in order to enable me to point out more clearly to the reader the nature of the *dependency* of *life* upon *death*.

Hitherto our investigations have been chiefly confined to the contemplation of matter while in the *second* of the foregoing conditions. That is, we have been chiefly engaged in considering the effects produced *upon dead or unorganized* matter by the *imparting or communication* thereto of some vitalizing or organizing cause; we have been contemplating, in a word, the cause of the *life* of such matter. In relation thereto we have followed such matter (that is, matter which had *originally* been dead or inanimate) while in the act of passing from the unorganized to the vegetable world; while in the act of ascending in the vegetable kingdom; while in the act of passing from the vegetable to the animal world; and, finally, while in the act of ascending in the animal kingdom. During the period that each of these transitions (which were effected by *the process of generation*, and constituted what is termed "*the process of nutrition*"), during the period, I say, that each of these transitions was in progress, we saw development given to what we understand by the phenomena of *living*. But such is not the *sole* aspect under which organic phenomena should be contemplated; they should be reviewed in another, an opposite, and a no less important relation. We should contemplate the effects produced upon *vitalized or organized* matter by the *withdrawal or resignation* of the vitalizing or organizing cause; we should contemplate, in a word, the cause of the *death* of such matter.

I have already directed my readers' attention to the fact, that it was during, and alone during, the period that the simplest conceivable vegetation, and what I have termed its specific stimulus (viz., nutriment)—namely, inanimate or mineral matter were reciprocally acting upon each other, that those two entities *conjointly* constituted what we understand by a *living* being. We were *then* chiefly contemplating the process of *living* in that vegetation I am now desirous of contemplating in the *same* vegetation the opposite process or *process of dying*. For, upon a closer analysis of what was taking place during the reciprocal action of those two entities upon each other, we shall find that what *one* was *obtaining* the *other* was *losing*; we shall find that at the same time, that the process of the elevation of dead or inanimate matter to the organized condition was in operation, another and directly opposite process was also in progress—namely, the simple vegetation which was conferring that organization was itself undergoing the process of disorganization or degeneration was itself *descending* in the scale of organization. When its function was finished, that vegetation was reduced to the condition of inanimate matter. In a word, when its function was finished that vegetation was *dead*. Let us now rapidly again trace unorganized or mineral matter from the dead or inanimate world in its passage through the vegetable and animal kingdoms; let us again watch the succession of changes which takes place in that matter till it has eventually become muscular fibre. Let us do so—*not* for the purpose of again contemplating the process of *living* in that matter, but for the purpose of ascertaining *how that process* is *dependent* upon the process of *dying*. The following is that succession of changes—namely, *while* the simplest organizing agent was in the act of conferring organization upon inorganic or mineral matter, and generating therefrom its own type and an organized residual product, the process of *living* was in operation, for inanimate matter was in the act of being elevated in the scale of organization; but the *organizing agent* which was conferring that organization was, itself, resigning or parting with its organized condition, was, *itself*, descending in the scale of organization. In a word, that *organizing agent* was undergoing the *process of dying*. When its function was completed that *agent* was dead; was reduced to the condition of mineral matter. *While* the albuminous atom was in the act of conferring (increased) organization upon the matter prepared for it by an humbler atom, and generating therefrom its own type and an organized residual product, the process of *living* was in operation, for that *organized residual product* was in the act of being elevated in the scale of organization; but the *organizing agent*—(namely, the albuminous atom) which was in the act of conferring or imparting, that organization was, *itself*, during that period in the act of resigning or parting with its organized condition; was in the act of *descending* in the scale of organization. In a word, that *organizing agent* was undergoing the process of *dying*. Thus, then, we have traced inanimate or mineral matter to its conversion into vegetable albumen, that is, we have traced such matter till it has become prepared to leave the vegetable and enter the animal kingdom. And what have we learned as *regards death* during that passage? We have learned these two (as I regard them) most important physiogical facts—namely, 1st, that each *succeeding step* in the ascent of that matter, during its passage through the vegetable world, is *indispensably dependent* upon the disorganization and ultimate *death* of the *organizing agent* which was the cause of that ascent; and 2nd, that during that ascent no *organized residual product* has undergone the process of disorganization and ultimate *death*, but, on the contrary, that at each succeeding step in that ascent the organization of such organized residual product has been augmented. Let us follow that albumen in its passage through the animal world, and we shall find the same results to obtain *till the final or ultimate products of generation* (or "*nutrition*") *have been formed*. *While* the fibrinous atom was in the act of conferring increased organization upon albumen, and generating therefrom its own type and an organized residual product, the process of living was in operation, for albumen was in the act of being elevated in the scale of organization, or in other words, fibrin was in the act of being generated; but the *organizing agent*—(namely, the fibrinous atom) which was in the act of conferring or imparting, that organization was, *itself*, during that period in the act of resigning or parting with its own organized condition; was in the act of *descending* in the scale of organization. In a word, that *organizing agent* was undergoing the process of *dying*. So, too, during the generation of muscular fibre. *While* the muscular atom was in the act of conferring increased organization upon fibrin, and generating therefrom its own type and muscular fibre, the process of living was in operation, for fibrin was in the act of being elevated in the scale of organization, or in other words, muscular fibre was in the act of being generated; but the *organizing agent* (namely, the muscular atom) which was in the act of conferring or imparting that organization was, *itself*, during that period in the act of resigning or parting with its own organized condition; was in the act of *descending* in the scale of organization. In a word, that *organizing agent* was undergoing *the process of dying*.

We have now reached the *final result* of the process of *generation*, or of what is popularly termed "*the nutritive process.*" With the generation of those results we have done

We collect this, as it appears to me, all-important result—namely, we arrive, as I regard it, at the true nature of *the distinction between a vegetable and an animal.* And what is that distinction? It is, as I regard it, this, namely—in the *animal* the *de*-generation of *an organized residual product* takes place; in the vegetable *no such* degeneration occurs. The function of the vegetable is *single*—namely, the *generation* of organized structures; the function of the animal is twofold—namely, 1st, the *generation* of organized structures; and 2nd, the *de*-generation of those structures to give development to "the phenomena of *animal* life." The vegetable world has been formed to *generate* a variety of *organized residual products*, the generation of which (as I shall attempt to point out more distinctly in a note) is of necessity accompanied with the *de*-generation or disorganization of *the organizing agents* through whose instrumentality or agency such generation was effected, but the generation of which is *never* accompanied with the *de*-generation of *an organized residual product.* The animal world has, in like manner, been formed to generate a variety of organized residual products, the generation of which is, in like manner, inseparably associated with the *de*-generation or disorganization of each of those *organizing agents*, through whose agency or instrumentality such generation was accomplished or brought about; and in it, too, in like manner, as in the vegetable world, the generation of such products is *never* associated with the *de*-generation or disorganization of *an organized residual product.* But the animal has an *additional* end to accomplish in Nature; has *another* and all-important function to fulfil. It has to develope "the phenomena of *animal* life." The development of *such* phenomena (and of such phenomena *exclusively and alone*) is inseparably associated with the *de*-generation or disorganization of *organized residual products*—namely, of the *final* results of "*the nutritive process.*"

In a note I shall attempt to point out to the reader how *completely* the phenomena of *life* are *dependent* upon the phenomena of *death*; and that 1st, in the *vegetable* world we have the *de*-generation or dying of an *organizing agent* of necessity going on simultaneously with the generation or living of an *organized residual product*, these two processes in conjunction, giving development to the phenomena of *organic* life, and constituting the process of *living* and of *dying* in the vegetable world; and 2nd, in the *animal* world we have the *same* two processes—(namely, that of *living* and of *dying*) in operation to give development to the phenomena of *organic* life; or in other words, in operation for the *generation* of organized residual products; but we have in addition thereto (which we have *not* in the vegetable) the *de*-generation or dying of an *organized residual product* of necessity going on simultaneously with the development of the phenomena of *animal* life, such as mental phenomena, nervous phenomena, and the phenomena of muscular motion. Thus, then, the foregoing may be briefly summed up as follows—namely, in the vegetable world there is but *one* species of vital phenomena, *because* there is but one species of *death*—namely, the death of an *organizing agent*, during the dying of which agent development is given to the phenomena of organic life. In the animal world there are *two distinct* species of vital phenomena, *because* there are two distinct species of *death*—namely, 1st, the death of an *organizing agent*, during the dying of which agent, development is given to the phenomena of *organic* life (namely, the *generation* of organized residual products takes place); and 2nd, the death of an *organized residual product*; during the dying of which product, development is given to the phenomena of animal life, such as mental phenomena, nervous phenomena, and the phenomena of muscular motion. In order to render my meaning more apparent, I shall illustrate. We see the oak of the forrest as year after year it advances in age, at the same time, *augmenting in bulk or dimensions.* We see the same throughout vegetable creation *universally.*

---

with the process of generation, or in other words, we have done with the phenomena of *organic* life. And what have we learned from the contemplation of those phenomena? We have learned those two (as I regard them) important physiological facts—namely, 1st, that the phenomena of organic life *consist in* the generation of *organized residual products*; (as also the regeneration of organizing agents whereby similar products may be re-generated) and 2nd, that the generation of those products is *dependent* upon the *death* or disorganization of the *organizing agents* through whose instrumentality those products were generated.

The function of muscular fibre, &c., has now to commence; in other words, now commence the phenomena of *animal* life. And how are those phenomena developed? It is, and let the reader impress this fact upon his mind; it is *by the disorganization* or degeneration of an *organized residual product.* Mark this well; we *no longer* have the disorganization of an *organizing agent*, but now (with the development of the phenomena of *animal* life) we, *for the first time*, have the disorganization of an *organized residual product.* We have the *de*-generation or *dying* of the *final results* of the regenerative process. What, then, do we collect *in relation to death* from the contemplation of the phenomena of *animal* life? We collect these two (as I regard them) important results—namely, 1st, that the development of the phenomena of *animal* life is *dependent* upon the *death* or disorganization of an *organized residual product*; and 2nd, that with the development of the phenomena of *animal* life commences, *for the first time*, the disorganization or *dying* of an *organized residual product.* Thus, then, the phenomena of *organic* life (that is, in other words, the phenomena of *generation*), which are common alike to the vegetable and to the animal, are *dependent* upon the *death* of an *organized agent*; whereas the phenomena of *animal* life, which are peculiar exclusively to the animal, are *dependent* upon the *death* of an *organized residual product.* I shall, in order to avoid misapprehension repeat the same in other words thus. The phenomena of *organic* life are *dependent* upon the disorganization or degeneration of entities which have been adapted by Nature *for causing or bringing about the organization of other materials.* The phenomena of *animal* life are *dependent* upon the disorganization or *de*-generation of organized structures *not* adapted by Nature *for causing or bringing about the organization of other materials*, but designed for the performance of some *other* physiological function.

If now, for perspicuity, and for the purpose of concisely summing up the foregoing remarks, I might venture for a moment to term the death of an *organizing agent* (*or atom*) *atomic* death; and the death of an *organized residual product* (in contradistinction thereto) *organic* death (more correctly in the *strict* application of terms, *residual* or *productal* death, but I am desirous, as much as possible, to avoid inventing new terms); if, I say, for this purpose, I might be permitted for a moment so to employ those expressions, the distinction between the vegetable and the animal might be thus briefly expressed—namely, in the vegetable world there is *organic* life, *dependent* upon *atomic* death, and such is all that takes place in the *vegetable* world; in the animal world there is *organic* life, *dependent* upon *atomic* death; and in additon thereto, there is *animal* life *dependent* upon *organic* death.

There is, at first sight, an apparent paradox in stating that a structure is *dying* while in the act of giving manifestation to *vital* phenomena, which arises from the *inseparable association* of the phenomena of *death* with those of *life*, and which from the nature of that association it would be difficult to avoid. It requires, however, but little reflection to perceive that this paradox is more apparent than real, and after a most careful and mature consideration of the entire of the subject, no terms have suggested themselves to my mind which, I considered, would enable me to lay more clearly before my readers what I regard to be *the nature of the dependency of life upon death.*

There is one additional topic (in connexion with the regenerative process and its dependency upon death) of the greatest physiological importance, but which I find it would be impossible advantageously to investigate at present. The question to which I refer is as follows—namely, *why* is there any *limit to the duration* of the nutritive process in organized beings? *Why* is not that process continuously renewed for an *indefinite period?* This question is important, and (as I believe) admits of a simple reply, but its investigation involves the consideration of a topic which I have considered undesirable to introduce into the present series of papers, as I hope at some future period to be permitted to enter upon its full investigation.

Not so with animals—not so with man. We see that when man has attained to, say, about one-fourth of his period, *his corporeal development ceases*. Why is this so? Simply for this reason, that the *organized residual products*, such as the *fibre of wood*, when they have been completely developed, *do not undergo the process of dying in the oak*; are *not*, in a word *again*, depressed or degraded in the scale of organization, whereas, the *organized residual products*, such as the *fibre of muscle*, when they have been completely developed, *do undergo the process of dying in man*; *are*, in a word *again*, depressed or degraded in the scale of organization.

We have now, determined the reply to the questions at present before us—namely, *how* and *where* (when generated *within* the parietes of the vascular system) is fibrin appropriated to the purposes of "*nutrition?*" The answers to those questions are these—namely, 1st, fibrin contributes to what is popularly termed "the nutritive process," *by stimulating* to the discharge of their specific physiological function, those *organizing agents* whose functions are to *generate* from that fibrin the *animal* tissues, such as muscular fibre, &c.; and 2nd, that the appropriation of fibrin to the generation of the animal tissues takes place in the *extra*-vascular interstices or *externally* to the parietes of the vascular system.

In my next communication I shall make a few observations upon the application of these facts to the general subject of our present inquiry.

(To be continued.)

EXTRACTS FROM A PAPER ON EPILEPSY.

(Read before the Midland Branch of the Provincial Medical and Surgical Association, at Derby.)

By JOHN HITCHMAN, M.D.

THE first case, H. D., was found dead in bed. She had retired to rest in her usual health. She was aged 50, and had been the subject of epilepsy for twenty years. Her intellect had become greatly weakened from this cause, and she was partially paralyzed in the left leg. The autopsy revealed the following appearances:—The body was well nourished; the lips were livid, and the neck, especially at its posterior and dependent positions, was of a bluish hue, not from bruises but from venous gravitation, and ordinary post-mortem change. She was examined at two p.m., eight hours after being seen in the morning. The same marks which characterized the neck were also present down the back and other parts; the calvarium was normal in shape, and of average thickness; the dura mater was healthy; the arachnoid membrane was not thickened or otherwise diseased; the pia mater was congested with blood, and the brain generally shared in this condition, in all probability induced by the mode of death. The upper surface of the convolutions of the cerebral hemispheres presented here and there hard knotty indurations, which varied in size from that of a pea to a large bean, but of a corrugated and rounded figure, while others were more elastic and smooth. These indurations proved to be small cysts, and the difference in their characters of hardness and form was found to arise from the circumstance, that the harder and corrugated ones had lost their fluid, and now contained a white grumous material, resembling an impalpably fine mortar, and in which, by the aid of the microscope, could be seen a large number of very minute crystals, having a rhombic figure. Those possessing fluid contained within this a few clear spherules, of varying microscopic size, adhering to their inner surface, but none on their exterior; each cyst was distinct in itself, forming in this respect a great contrast to the acephalocysts occasionally found in the uterus and other organs; indeed their solitary character induced my friend, Dr. Hodgkin, and myself, to look most carefully for that curious entozoon, the cysticercus cellulosus, which has been occasionally found in solitary cysts occupying the brain and the eye of the human subject, but without success. A small solitary cyst, less than a pea, was found on the upper surface of the left lobe of the cerebellum. The vesicular neurine of the convolutions exhibited no disease beyond the immediate contiguity of these little bodies, and even at that spot nothing further than a depression, caused by their presence, could be detected. Whether this depression was induced by simple pressure, without any loss of nervous substance, or whether it had given rise to atrophy, could not be well determined upon. I am inclined to think the latter. The vesicular and fibrous portions of the brain were each much congested with blood, which we regarded rather as a moribund effect than anything else (as the patient had died, in all probability, from asphyxia), and we discovered no other change until we reached the left ventricle, where, resting upon the corpus striatum, was another cyst, of considerable magnitude, as large, indeed, as a pigeon's egg. In this large cyst, the walls had a distinctly laminated texture, and small clear globules or spherules were studded over its inner surface, resembling the "hyaline" which has been so fully described as to its properties by Barry and others, and which, in truth, were young cells, slowly forming into other acephalocysts. The corpus striatum around this larger body was softened in its structure, and had undergone some diminution. The brain presented no other disease. The choroid plexuses, in common with the blood-vessels of the brain generally, were in a congested condition. The right lung was gorged with blood, and the patient was considered to have died from "pulmonary apoplexy;" in fact that was the verdict returned (from medical testimony) at the coroner's inquest. No other disease was found in the chest, and the viscera of the abdomen were remarkably healthy.

In contrast with the above case, was one which I saw in 1849, in which there were spiculæ of bone protruding from the inner periosteum of the skull (dura mater), and resting upon the brain—*i.e.*, resting upon, although not piercing the pia mater; the cerebral lobes were of unequal size; the superior longitudinal sinus was literally encased in bone; the choroid plexuses contained small cysts, and the basilar arteries were loaded with atheomatous deposits; and yet this patient had never experienced epilepsy. On the 23rd of January, 1849, I examined an epileptic in whom there was the same singular irregularity in the size and form of the cerebral hemispheres. In this case, the left anterior cerebral lobe was very much larger, and three-quarters of an inch longer than that on the right side; the vesicular neurine of both lobes was soft, and varied in hue, from a dark brown to a pale fawn colour; the middle lobe of the cerebellum was much shrunken and atrophied, and had a pale macerated appearance, like to animal structure which had been long immersed in fluid. But in this case, the pituitary gland was extensively disorganized, degenerated in fact, through the greater part of its structure into a gritty, earthy substance; and the clinoid processes of the sphenoid bone were so elongated as to project and to press upon the superjacent parts of the cerebrum. These two latter cases are, I think, highly instructive by contrast, as *proving* that the inequality in the weight, size, and form of the anterior cerebral lobes, belongs rather to the lesions of insanity than to epilepsy. For I ought to have stated at the outset, the important fact, that the patients to whose autopsies I refer, were not only epileptic but insane. It would certainly vitiate all our reasonings if part had been insane and part otherwise; but as all were of unsound mind in an equal degree,—as the condition of each were equal, I do not think this circumstance will much invalidate the usefulness of the facts recorded.

The second case who died from epilepsy, on the 18th of December, 1849, was aged 56. She had been insane eleven years, and epileptic forty-eight years, the epilepsy having been produced by a blow. When eight years of age she was knocked down by an infuriated cow, and her frontal bone fractured by the blow. In the autopsy, the calvarium was found to have a deep indentation of a triangular form in the centre of the frontal bone; this was limited to the first table, as no corresponding mark was visible on the cerebral surface of the bone. The inner table was deeply grooved by the meningeal arteries, and had become so thin as to be diaphanous. The base of the skull was of a con-

tracted form; the ethmoid process, "crista galli," was very large and projecting; and the clinoid processes of the sphenoid were curved and irregular; the dura mater was firmly adherent to the skull; the arachnoid was opaque and thickened; the pia mater much congested; the Pachionian bodies were very large; the pituitary body was atrophied, and in a degenerate condition; the medulla oblongata was much congested with blood, and I should have said, that the lateral ventricles were devoid of fluid. The heart was small and flaccid, and its tricuspid valves were diseased and thickened. The other viscera of the body appeared healthy. I wish to contrast this with another autopsy conducted by me in 1845. E. L., died from a fungoid tumour of the dura mater. She had exhibited great passiveness of character and simple imbecility of mind. She had for more than one year suffered extreme pain on the left side of the head, along the lower anterior edge of the parietal and across the temporal bone, at which point she had received a severe blow in a quarrel some five years prior to my seeing her. When I first saw her, the left eyelid was paralyzed, and drooped over the eye; the pupil was enormously dilated, and vision was extinct. For a fortnight before she died, she experienced great pain and difficulty in the act of deglutition, and for the three latter days of her existence, was unable to accomplish it. For the same period, the left nostril was insensible to snuff and some other irritants. On examining the skull after death, it was evident that the blow had left a deep scar over the left temporo-frontal region; this appeared to have excited inflammation of the dura mater, and to have given rise to the tumour, which has been already named as the cause of her death; for although it was not immediately opposite the seat of injury, yet the membrane from a point opposite to the external scar, was most intimately adherent to the bone. The tumour, which was placed somewhat obliquely in the base of the skull, pressed on the left optic nerve at a point anterior to the outer edge of the crus cerebri, as it was passing forward to join its fellow nerve. The scirrhous thickening was, however, more conspicuous, harder, and larger, upon and in front of the petrous ridge of the temporal bone, embracing within its substance the semilunar ganglion, protruding forwards and inwards, pressing on the outer edge of the cavernous sinus, and completely imbedding, anteriorly, the first, third, and second divisions of the trifacial nerve, as they respectively passed to the cavernous sinus, the foramen ovale, and the foramen rotundum. In consequence of some unavoidable delay, the brain had become too soft for a satisfactory examination. It will strike you, how completely the disease was illustrated by the necroscopic appearances; in other words, anatomically, by the loss of sight on the same side, as it pressed on the *outer* edge of the optic nerve prior to its conjunction; in the paralysis of the upper eyelid, as it encroached on the motor oculi nerve, on the ophthalmic branch of the fifth, and ultimately interfering with and interrupting mastication and deglutition, by its pressure on the superior and inferior maxillary nerves, and probably, from the same cause, destroying sensation in the lining membrane of the left nostril, as the throat and nose were free from disease.

A blow upon the frontal bone immediately produced in the former case an epileptic paroxysm, which occurred at intervals through forty-eight years, ultimately inducing mental derangement and death. A similar force at the junction of the parietal with the temporal bone did not originate epilepsy, but gave rise to a malignant tumour, which encroached upon and destroyed some of the agencies of vision and muscular action, and, by mechanical contiguity, impaired the intellectual manifestations of the brain, and finally destroyed life. How are we to explain these discrepancies? Are such phenomena limited to diseases of the encephalon, or are they found to exist in the other structures of the body? Can a rational explanation be found in the circumstances attendant upon the injury? or will our present knowledge of the structure and functions of the varying parts involved in the respective lesions furnish it? In the latter case, anatomy fully explains the entire range of objective phenomena; but how and where are we to seek for an elucidation of the presence of epilepsy in the one case, and of fungoid tumour alone in the other? I trust these questions are worthy the attention and the thought of intelligent medical men;—that you will not deem me frivolous in bringing them before your notice; but that you will kindly extend to me your indulgence whilst I proceed to the narration of the third autopsy, and to the detail of some facts connected with the previous history of the case.

M. A., who died from pulmonary consumption, in 1850, had been epileptic to an extraordinary extent for many years, especially during the six months prior to the manifestation of the thoracic disease. In the month of January preceding her decease she had as many as one hundred and sixteen paroxysms of epilepsy, reckoning that as a distinct fit which was followed by consciousness, for however brief a period the conciousness might have lasted. In this case, the severest I ever witnessed, there was no cerebral lesion, beyond opacity and thickness of the membranes of the brain, effusion of serum between the convolutions and into the lateral ventricles, and a very hypertrophied condition of the pituitary body. This organ was, however, most extensively diseased, and is a structure of far greater importance than its situation or its size might, *a priori*, intimate. This patient formed one of nine that I selected for especial observation, with a view to determine if any, and what amount of influence, the moon might exert in the production of the epileptic paroxysms. I have great faith in popular notions; that is, I believe they frequently contain a nucleus of truth, however much such nucleus may be covered with incrustations of error and folly; and, at all events, the supposition that such influence was exerted could only be disproved by carefully observed facts. Accordingly, nine epileptics were watched most assiduously for two months, and the facts duly registered. I shall weary you only with the particulars of one month. In no one day, nor within any one week, did *all* the nine cases experience an epileptic seizure; but eight out of the nine became epileptic during the first fourteen days of observation. M. A. had fits every day through the entire month; on some of these days she was scarcely exempt from its influence during any part of them. On the day of the new moon she had two paroxysms; on the seventh day of the moon's age she had five paroxysms; on the day of the full moon she had three fits, and on its entering its last quarter two paroxysms; on the recurrence of a new moon, two fits; on the twelfth day of the moon's age she had six paroxysms, and on the twenty-seventh day six fits. On the day of the full moon only two patients out of the nine had seizures, while on the seventeenth day, on the twenty-third and twenty-ninth days of the moon' age, four of the nine were beset with the malady. On no one day were more than four afflicted; and the largest number of paroxysms experienced in twenty-four hours by one epileptic was six. We therefore infer that although epilepsy is paroxysmal in character, it has no direct relationship to the condition of the moon, except, perhaps, in some rare, exceptional, and highly sensitive cases. It is, however, a remarkable fact that this patient, M. A., who had been epileptic for many years, who, through the entire period above referred to never passed a day without a fit, and who in one calendar month experienced above a hundred paroxysms, never was epileptic during the last six months of her existence. From the day that inflammation of the lungs set in until the day of her death from tubercular disease, she was free from the former malady. She was watched night and day by trustworthy nurses, under my own immediate supervision, and, therefore, upon this statement you may fully and implicitly rely. Here again, as it appears to me, an interesting question springs up,—What condition excitant of epilepsy was removed by the deposition of tubercle on the lungs.—*Prov. Jour.*

RHEUMATIC FEVER TREATED BY ACETATE OF POTASH.

(Under the care of Dr. Golding Bird.)

Many cases have been lately brought forward in which this disease has been treated with various remedies—as colchicum, acetate and nitrate of potash, and lemon-juice, respectively. The treatment of rheumatic fever by acetate of potash is the more interesting as involving the truth of Dr. Bird's explanation as to *why* this diuretic salt should be useful in rheumatism. After giving a detail of the solid matters found in the urine whilst the functions are in a normal state, Dr. Bird adds:—"But we also know that the researches of Wohler have shown us something more—viz., that whatever substances exist dissolved in the blood not necessary or fit for the reprair of the structure of our frame, invariably escape from the body by the kidneys. The injection of saline bodies, colouring matter, &c., readily proves Wohler's statement." The lecturer mentions a little further on, that the septic agents do not reappear in their original form, but that they undergo metamorphosis; and proceeds in these terms:—"Can we at will by therapeutic agents produce this depurating effect, and by hastening the metamorphosis of matter, aid the removal of a *materies morbi*, whether itself the exciting cause or effect of antecedent morbid action."

Before we state which are the *therapeutic agents* most likely thus to depurate the blood, we should mention what efficacy Dr. Bird ascribes to the increase in the secretion of the kidneys:—"It will be found that the increase of water does not escape alone, but there is really washed away with it a certain, although not very large quantity, of solid debris. . . . . This is a key to the cures effected by mineral springs. . . . . I would press upon the practitioner the importance of directing his attention to diuretics, not as merely helping the pumping off of the water, but as *renal alteratives*, as remedies aiding the removal from the body of injurious matter." The diuretic to which Dr. Bird gives the preference for removing the *materies morbi* in rheumatism is acetate of potash.

The first case was a girl aged 16, of sanguineous temperament, who traced her attack to sleeping in a kitchen underground. The disease commenced in the right ankle, soon reached the knee, and gradually attacked the left limb, as well as the shoulders. She was thus labouring under inflammation of the principal joints when admitted into hospital, at which period she presented the following symptoms:—Skin hot and dry; tongue slightly furred; pulse quick and full; slight headache. The wrists, knees, and ankles swollen, stiff, and painful, and yielding a dry rubbing sound on being moved. Bowels and catamenia regular; appetite tolerable; sleep very indifferent. Ordered twenty-five grains of acetate of potash to be taken every fourth hour in camphor mixture, and eight grains of Dover's powder at night. The patient was much better on the third day; she moved her wrists with facility, and without pain; the skin had become moist; she slept better; the bowels acted once a day; and the appetite was improved; pulse the same as before, and tongue more furred. The medicine was continued, and on the seventh day the ankles were free from pain, though the arms became somewhat stiff and swollen; all the other symptoms improving. On the fourteenth day, the pulse was natural, and the patient quite free from pain in any joint; the appetite was very much improved; and to each dose of the acetate of potash hitherto regularly taken every fourth hour, four grains of ammoniated citrate of iron were added, and the girl was desired to get up for two or three hours a day. The latter injunction was carried out to a greater extent than had been prescribed, and the consequence was a slight relapse on the seventeenth day; this, however, soon gave way, and on the twenty-first day the patient was discharged quite well.

The second case, an old woman, aged 29. Five days before her admission she had got very wet, and the same evening the right wrist became painful and swollen. The next day the knees, and subsequently the shoulder of the same side, became similarly affected. On admission, the right shoulder, wrist, and knee were exquisitely tender, as well as swollen and painful; the cheeks were flushed; there was headache, and sour-smelling perspiration; tongue covered with a dirty-white fur, and red at the tip and edges; pulse quick, full, and bounding; urine tubid and acid; great restlessness, and no sleep for several nights. Ordered half a drachm of acetate of potash to be taken every fourth hour in camphor mixture, and ten grains of Dover's powder at night. The doses were somewhat larger than in the preceding case, both probably on account of the difference of age and the severity of the symptoms. As the joints were exquisitely tender, soda poultices (the ordinary linseed poultice made with a solution of carbonate of soda instead of plain water) were applied to the affected articulations. On the third day the patient was considerably relieved; the bowels were, however, confined. Calomel and colocynth were ordered, and the acetate continued. The improvement was steady and gradual; and on the sixteenth day all the joints were well, with the exception of a little stiffness about the shoulder. The patient then took two grains of disulphate of quinine three times a day, and was soon quite well. The urine was in both cases considerably increased in quantity.

It will now be necessary to inquire for what reason Dr. Bird prefers the acetate of potash to other diuretics? If we turn to his lectures on the subject we find the following explanation:—

"Squill, copaiba, broom, juniper, &c., merely increase the fluids and are useful in dropsy. . . . . Remedies which exert no chemical action on organic matter out of the body, appear to be incapable of augmenting the quantity of solids in the urine, and hence are of use only in the elimination of water; they may and do act as renal hydragogues, but not as renal depurants. . . . . We have next to notice those remedies among the reputed diuretics which increase the metamorphosis of tissue and act as depurating agents. This class includes the alkalies, their carbonates, and their salts, with such acids as in the animal economy are capable of being converted into carbonic acid, including the acetates, tartrates, and citrates of soda and potash. These remedies act all alike—they all actively stimulate the functions of the kidneys, and increase the bulk of the urine; but they do more—they actually increase the metamorphosis of tissue by, in all probability, a direct chemical action on the elements of worn-out and exhausted tissue, or other matter in the capillary laboratory of the body."

As to nitrate of potash, Dr. Bird has found it inferior to the acetate of the same alkali. He has used the latter with much advantage, as he finds that "the quantity of fluid removed from the body by the nitrate of potash is far less than that which is carried off under the solvent influence of those agents which act more energetically on animal matter."—*Braithwaite's Retrospect.*

Prurigo of the Genital Organs.—This affection (which often assumes the form of lichen or eczema) is well known to be very painful, distressing, and difficult to remove. M. Tournié has lately proposed calomel ointment, and a powder of camphor and starch, which topical applications he has used with much success. When the parts (genital organs, anal region, or axilla) are covered with scabs, tepid baths, and emollient applications are to be used first. When the indurated particles are removed, the affected spot is to be rubbed twice a day with the calomel ointment (one to two drachms of the calomel to one ounce of axunge), and after each application dredged with the powder (four parts of starch to one of finely powdered camphor). We mention M. Tournié's treatment, as this kind of prurigo so often baffles the remedies usually employed.

REMARKABLE CASE OF RECOVERY FROM FRACTURE OF SKULL AND LOSS OF BRAIN.

By J. Snyder, M.D., of Virginia.

On the 15th of April, 1851, a son of Colonel Vaus Fox, about eight years old, was run over by a horse and thrown violently upon a rock jutting out of the ground, which fractured the skull very extensively. About two hours after the occurrence of the accident I was called to the case, and upon examination found the injury to be at the middle portion of the temporal arch, between the parietal protuberance and frontal suture, implicating a portion of the frontal bone. A portion of the parietal bone, precisely one inch and a half in length, and of an elongated triangular form, was forced endwise into the middle lobe of the brain, penetrating its investing membranes and entering its substance. Parts of the parietal frontal and temporal bones were fractured into five or six pieces, making a comminuted depressed space of four inches, which presented a perfectly concave apparance, with a wound in the centre of the depression about one inch in length. With the assistance of my friend, Dr. Pratt, after removing the hair, the wound was enlarged to the extent of one inch and three-quarters, to facilitate the extraction of a portion of the parietal bone completely hidden in the cerebral mass. After the wound was enlarged, I extracted the piece of bone with forceps, and removed about a dessert spoonful of the middle lobe of the brain, which followed its extraction and forced itself out of the wound. This done, the little fellow seemed to arouse up and regain his sensation—so much so as to make a considerable struggle and effort to rise, but was forced to remain quite by assistants. The struggle caused a second protrusion of the brain, which being detached from the cerebral mass, as we supposed, was cut away with surgeons' scissors. I then proceeded to raise with an elevator the depressed pieces of bone to their normal position, which was accomplished with considerable difficulty, being compelled to use a good deal of force. It was, however, accomplished satisfactorily, and the wound dressed with emp. adhæsiv. and a light compress, leaving a small space between the strips to permit the blood, &c., to escape. During the operation the little fellow was perfectly comatose, except for a moment immediately after the extraction of the bone. He was now placed in a well-ventilated and quiet appartment, closely watched, and under the constant surveillance of a doating mother. Although a very tractable and obedient child, yet it was necessary for these around him to watch him closely, as his position was frequently and abruptly changed from side to side with quick and sudden tossings, which made it necessary for his attendants to stand by to retain him in bed and to adjust the cover. He frequently placed his hands on the wounded part, but complained of very little pain. He was very closely watched during the night and next day by Dr. P. and myself; and on the following night, about thirty hours after the operation, reaction took place, which required, for the protection of the brain, three copious bleedings, about an hour apart. This free abstraction of blood had the desired effect of reducing arterial action, and quieting the whole system.

On the following day it was thought best to excite the bowels to action, which was done by enemas, and subsequently by giving quarter minim doses of l. c. tiglii, mixed with bread crumbs, repeated every two hours until some effect was manifested. After this an occasional pill of the same was given, which, by one or two repetitions, always acted pleasantly. No further evidence of excitement manifested themselves during the progress of the case. The head was cleansed and dressed twice a day, for a few days, and subsequently but once a day, and recovery was unexpectedly rapid being only three weeks before he was able to walk in his room, requiring no change of treatment; and the little fellow is now (August 10th) in robust health and fine spirits. As is usual in this character of injury, I feared the occurrence of fungus cerebri, but these unpleasant consequences have not shown themselves, and it is not probable that any thing of the kind will arise, as it is now four months since the accident; and I feel confident his intellectual faculties have not sustained the slightest degree of injury. On the 16th of August, four months after the accident, he had an attack of scarlatina simplex, which passed off without an unplesant symptom, and without any medical treatment other than a tepid bath and confinement to his room.

What is most remarkable in the above case is, that an injury so extensive, involving so much of the skull and a loss of so much of the cerebral mass, should recover so soon, and with so little medical assistance.—*Virginia Med. Gaz.*

CASE OF SPONTANEOUS COMBUSTION.

By W. J. Byrne, M.D.

On the night of the 16th of August, Mrs. S——, residing in Logan County, Kentucky, was left sitting up, by her daughter, who retired at nine o'clock. About ten o'clock she was awakened by a most loathsome stench, and discovered a small flame playing about where her mother should have been sitting. She discovered at once that something strange had occurred, and immediately ran to her brother's, some three or four hundred yards distant, to obtain assistance. By the time she returned, the whole person of her mother, with the exception of the left leg, from about the middle of the femur down, and the right leg from the knee-joint down, was entirely destroyed. At the time of their return, a light, small, blue flame was playing about the femoral end of the left leg; they immediately threw some water upon it, which checked it, though at its application the flame seemed to be momentarily increased. All the clothing upon her was burned up. Of her head, trunk, and upper extremities, nothing was left but a pile of ashes. The lungs, heart, and liver retained their form perfectly, jet black in colour, presenting the appearance of charcoal made from burning cork, and were very light. A small portion of the spine, from about the first lumbar or last dorsal vertebra to the middle of the sacrum, was also left in the same condition, and presented the same appearances. The ilium, pubis, &c., were completely destroyed, not a vestige of bone remaining. The portion of the left leg that was unconsumed was black, heavy, and crepitated under the pressure of the finger; the remains of the right leg (from the knee down) presented the same appearance, with the exception that all the parts comprising the portion between the phalangeal extremity of the metatarsus back to about the middle of the tarsus were reduced to ashes.

Her daughter states that she left her mother smoking, sitting upon the edge of the hearth; that there was no fire of any consequence in the fireplace; that the little that was there was well covered up with ashes, which was found unopened when she made the statement. The chair upon which Mrs. S. was sitting was almost destroyed, nothing being left but about four inches of each post, which small portion was charred and scorched. From the position in which her remains were found, it seems she must have fallen forward upon the hearth, her pipe being found by her side. The odour was strongly empyreumatic, and around her was deposited a fœtid and most fuliginous deposit of a greasy character. The subject was was upwards of 70 years of age, and for the last thirty years had been strongly addicted to the use of ardent spirits, sometimes drinking enormous quantities, and was very fleshy. Her general health was good up to the time of her decease.

A question now arises as to its being a case of pure spontaneous combustion. Now, she had a lighted pipe; could no the origin of the combustion be attributed to it? Or should we rather call in the aid of the calorific powers of the electric fluid? Or was it truly a case of spontaneous combustion, and owed its origin to the disengagement of phosphuretted hydrogen or to the caloric developed by those internal actions which determine a highly combustible state of the body?—*Nashville Jour. Med. and Surg.*

REVIEWS AND NOTICES OF BOOKS.

LECTURES ON THE PHYSICAL DIAGNOSIS OF THE DISEASES OF THE LUNGS AND HEART.

By Herbert Davies, M.D., Senior-Physician to the Royal Infirmary for Diseases of the Chest, Assistant-Physician to the London Hospital, &c. &c. London. 1851. Post 8vo. pp. 288.

These lectures, which were originally delivered at the Royal Infirmary for Diseases of the Chest, appeared, in part, in the *Lancet* for the year 1850. In publishing them, the author states that he has a two-fold object in view; 1st, "to collect and arrange, as concisely as possible, for the use of the student, the facts which relate to the theory and practice of auscultation and percussion; and 2ndly, to direct the attention of his medical brethren to the labours of the distinguished School of Vienna, of which Professor Skoda is the acknowledged head and founder."

The first lecture contains some statistics of diseases of the lungs, followed by an outline of the anatomy and physiology of the organs of respiration. From a table given in this place it appears—

"That at least two-fifths of the deaths from diseases of the lungs occur at and under the age of five years.

That pneumonia is extensively fatal in early life, nearly eighty per cent. of the deaths from that disease occurring at and under the age of five years.

That the deaths from bronchitis are most frequent at and under the age of five years, being nearly in the proportion of thirty-three per cent.; and that above that age and under twenty-five, the mortality is at a minimum, increasing from that period upwards.

That ten per cent. of the deaths from consumption occur at and under the age of five years; that the maximum of mortality is between fifteen and forty years of age, amounting to nearly sixty per cent. of the entire number of fatal cases from this disease—a statement which closely accords with the experience of the medical officers of the hospital at Brompton."

In the second lecture, the author proceeds to the consideration of the special subject of the course, viz., "the means by which thoracic diseases are to be detected;" which are considered in the following order:—

1. Spirometry, 2. Inspection,
3. Mensuration, 4. Palpitation, 5. Succussion,
6. Percussion, 7. Auscultation.

Dr. Davies devotes a lecture to the spirometer, and the indications which it is capable of affording in determining the presence or absence of disease in the chest. He prefers a modification of Mr. Hutchinson's spirometer, introduced by Dr. Pereira. This instrument, which is a model of a gasometer on a small scale, consists of "a large glass cylinder, suspended by means of a cord in a reservoir of water, the cord passing over a pulley, and having a weight attached, so that by proper adjustment the cylinder may balance in any position; a pipe, forming the continuation of the tube through which the patient has to breathe, rises in the bell-glass above the level of the water, and by forcing the air through this tube the vessel will ascend, and indicate, by a graduated scale affixed, the quantity of air passed into it. The principle of the machine is very simple, and its use easily acquired. It will be found, upon experiment, that the number of cubic inches capable of being expelled from the lungs after a full inspiration, by an individual in good health, is liable to such little variation, that the vital capacity may be considered as a constant quantity."

The vital capacity as indicated by the spirometer, is influenced by the following circumstances:—

1. The height of the individual.
2. The age.
3. The weight.
4. The disease.

The *height* of the individual appears to be the chief condition which regulates his vital capacity; "so that, as a general rule (subject to a few corrections), we may determine the height of a healthy individual from a knowledge of the number of cubic inches of air which he is capable of expiring." *Weight* forms, also (the author observes), "an important element in the calculation, although its effect has not yet been fully determined from the circumstance that the standard weight of an individual of a given height and age remains undecided."

Age.—We should naturally expect the inspiratory power to share, with the other functions of the body, in the vigour which characterizes the adult period of life. Experiment confirms this view. The vital capacity is found, *cæteris paribus*, to be at a maximum between the ages of thirty and thirty-five, and to fall gradually after the latter period, at the rate of nearly one and a half cubic inches for every additional year.

Disease.—We have now arrived at the most important element of variation, for the detection of which the spirometer is, of course, intended. It is quite evident that, if it is possible to determine, *à priori*, the standard vital capacity for all heights, weights, and ages, that the instrument puts us in the possession of a means of deciding upon the normal or abnormal condition of the respiratory organs of any person subjected to an examination by it. This is the basis of all our views respecting the spirometer; and the three thousand experiments made by Dr. Hutchinson provide the standard of health in question.

. . . . . .

From the observation of many hundred cases of suspected tubercular disease of the lungs, I have learned that a marked diminution of the vital capacity is an important indication of the disease in question, and that this condition of the inspiratory power is always antecedent to such a manifestation of the local signs as would be sufficient to warrant us in giving a decided opinion upon the existence of the affection."

As an example in point, Dr. Davies quotes the case of Freeman, the American giant, who was at one time an outpatient of the London Hospital, previous to which period he had been examined by Dr. Hutchinson, who found the following to be his measurements:—

"Height 7 feet; weight 19 stone 5 pounds; circumference of chest 47 inches; vital capacity 434 cubic inches. Two years subsequent to this period he was taken ill, and although complaining of some dyspnœa no trace could be found at the time of the deposit of tubercular matter in his lungs. An examination by the spirometer, however, showed that his vital capacity had sunk to 344 cubic inches. In a year from this time he had fallen a victim to consumption. This case fully indicates the value of the spirometer; and by the experience derived from extended series of observations made with it, I have come to the conclusion that a very small amount of tubercular deposit is sufficient to produce a great dimunition in the natural elasticity of the lung, and a corresponding reduction in the vital capacity."

The third lecture is devoted to percussion. The author prefers the fingers to any of the instruments which have been recommended for the purpose. "I have made use (he says) of all kinds of hammers for percuting, and a great variety of plates (bone, metal, leather, gutta percha, and membrane) for receiving the blow, but have abandoned them all for the fingers of the right and left hand, which answer admirably for hammer and plate."

Dr. Davies adopts the division of percussion sounds laid down by Professor Skoda, who arranges them into—1, a full tone and its opposite, an empty tone—2, a clear tone and its opposite, a dull tone. "By fulness is meant (he observes) a considerable volume of sound. Thus a large cathedral bell, even when muffled, and vibrating weakly, conveys the idea of a large mass in motion, while a small hand-bell, however distinct its tinkling tone may be, cannot be mistaken for one of a large size. Our ideas of size, as derived from sound, depend upon the degree of the fulness of tone."

After having considered the varieties of resonance elicited by percussion of the healthy chest, the author devotes a short space to the alterations produced by disease, and quotes here the following summary from Zehetmayer's work:—

"The air of the cavity of the chest may be—

1. Abnormally increased in quantity.
2. Abnormally diminished in quantity.
3. Entirely absent in certain parts.

1. Abnormally increased.

A. Generally. B. Locally.

A. Generally.

1. In vesicular emphysema, the sound being clearer and fuller than natural, and extending beyond the ordinary limit of the healthy lung.

2. In pneumothorax, with or without empyema, the tone is clear, full, and tympanitic, provided the thoracic walls are not too tightly stretched.

B. Locally.

1. In hollow cavities, a clear, empty sound, often metallic or associated with the bruit du pot fêlé.

2. In partial emphysema, particularly at the edges of hepatized or tubercular infiltrated lung, the tone is clear, empty, and sometimes tympanitic.

2. Diminished in quantity.

1. In bronchial catarrh, the sound upon percussion is not altered, unless some alterations in the parenchyma of the lung are coexistent.

2. In the first and third stages of pneumonia the dulness of the sound is proportional to the number of lung-cells filled with secretion.

3. In œdema pulmonum, the same.

4. In small effusions into the pleura, union of the pleura by false membranes &c., the tone is less full and sonorous.

3. Total absence of air from—

1. Deposition of fibrin, tubercular, and encephaloid matter, in the lung-cells and inter-vesicular tissue (apoplexia pulmonum, hepatization, phthisis, cancer, &c.). In these cases, the sound on percussion is dull to an extent proportional to the quantity and completeness of the lung consolidated.

2. On compression of the general parenchyma in consequence of—

1. Effusions into the pleural cavity. { Pleuritis. Hydrothorax.

2. Tumours pressing and encroaching upon the lungs—as aneurism of the aorta, hypertrophy and dilatation of the heart, exudation into the pericardium, morbid (cancerous) masses, ascites, enlargement of the abdominal organs," &c. &c.

The remaining lectures of this part embrace "inspection, palpation, the normal respiratory murmur, bronchophony, œgophony, bronchial respiration, rhoncus crepitans, crepitation, amphoric resonance, metallic tinkling, and the stethoscope." In the tenth lecture, the physical diagnosis of the diseases of the heart is commenced, and is continued through seven lectures; under the heads "position, measurements, innervation, impulse, inspection, palpatation, percussion, and auscultation."

Each of the foregoing subjects is very ably handled, and we must say the author has succeeded in producing an excellent practical manual. The literature of the subject, too, is fully up to the present day, while no improvement of any importance in its bearings upon physical diagnosis has been overlooked.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JANUARY 21, 1852.

OPERATION OF THE DISPENSARY ACT.

The capabilities of the Dispensary Act are subjected to severe trial and its powers must speedily be thoroughly tested. The proceedings of the Guardians are still pending and the interference of the Commissioners is only commencing, therefore are we unable to ascertain results; but sufficient transpires to prove that great difficulties have to be surmounted, and that much vigilance must be observed to prevent bad precedents from becoming established. Districts excessive in dimensions and salaries inadequate to the duty, are the questions at issue, and upon them the Commissioners will have to decide, for the Guardians in many places seem bent on resistance to the just claims of both surgeons and patients. In some places the determination to defeat the objects of the bill altogether seems to prevail. The Tralee Union has been divided into four districts, but the Commissioners recommended six, some of the districts already named being twenty miles long; the Guardians, however, still stand out for the rateyayer, one of the minority in favour of a proper division sarcastically remarking, "we have not heard much about the expense of Dispensaries under the old law. Why? Because the greater part of the burden was borne by the occupiers; but now there is great commotion because the landlord must pay half." This is the truth, but both landlords and ratepayers must submit to their fate. They are paying for public works, police, poor-rates, hospitals, lunatic asylums (and the nation at large, for schools) some two millions. They must also pay for the medical relief of the poor, and they may as well do it with a good grace. In other unions, they are revising, rescinding, and curtailing, but it is all in vain, for sooner or later the law must be obeyed, and it will save a world of trouble, wrangling, and mismanagement if the Commissioners will frankly tell them so. In the Mountmelick Union much difference of opinion prevails as to the number and grouping of the districts, and a correspondence with the Commissioners has taken place. The original division into eight districts is, however, retained; but the grouping of the divisions is under consideration, the arrangement as to the large town of Portarlington being faulty. Here, and probably in other places, the town is on the confines of two districts, so that the poor of it and the vicinity, although necessarily numerous, must go a considerable distance for relief. It is obvious that the act never contemplated such an arrangement as that which would leave large towns without Dispensaries, and we conclude that in this case the proposed plan may be modified without prejudice to any one. In Gort—

The guardians first divided the union into two districts, but the inspector, Mr. R. Bourke, remonstrated and said, that three would be little enough. The area in acres is 107,576. The population in 1841 was 39,000—the poor-law valuation is £47,222. A fortnight's notice was given to take Mr. Bourke's suggestion into consideration, and the result in the end was the same; the board persisting in having but two dispensaries, embracing the above area between them, and each ranging a distance of twenty-three English miles by twelve, and for the performance of the duties have fixed on the munificent sum of £50 per annum as the surgeon's salary. The argument adduced in favour of that sum being sufficiently adequate is, the fact of the same duties having been performed by the workhouse medical officer for the last twelve months, who was appointed under the 10th of Victoria to a dispensary at Gort, consisting of ten electoral divisions (half the union), and that *he neither then, nor now, remonstrated against the inadequacy* of the salary, and that when *he* was satisfied with £50, the speaker (Lord Gort) did not see why he should get more; and if the duties of the Gort district would be done for £50, why not Kinvara for the same? Dr. Hynes, who held the Kinvara Dispensary under the Grand Jury Act, and who is a guardian, said, that what had been given by that board under the 10th of Victoria to a gentleman who held two other situations—the workhouse and fever hospital also under it—should not be laid down as a criterion for the salary of a district having no other connexion with the board, particularly when he recollected that the salary alluded to had been reduced from £91 15*s.* to £50 per annum, solely on account of the other appointments held under the board at the time. A very bad principle, he stated, to go by; but still as the board was guided by it, he could not avoid alluding to the real cause of the salaries being hitherto only £50. Dr. Mulville, who is

also a guardian, followed, and proposed (after designating £50 a downright absurdity) £100 as the salary, but without successs.

Our readers will recollect that this is exactly what we predicted would be the effect of one surgeon undertaking the care of two institutions under the same paymasters. We feared that they would never pay double salary for double duty. Local circumstances may, however, require expedients not in conformity with general policy, and we must refrain from pressing a rule for universal application.

DENIAL OF PAYMENT TO MEDICAL WITNESSES.

Dr. Hynes of Kinvara, has addressed the following appropriate note to Dr. Kingsley of Roscrea, in every word of which we cordially concur. This is an old grievance, and now that a regular debtor and creditor account is fairly opened between the medical profession and the public it must be dealt with. The time has arrived for every medical practitioner to assert his right to payment for his services, whatever they may be:—

My Dear Sir,—I enclose a post-office order for 15*s*., which I will thank you to forward to the treasurer of that invaluable institution of which you were the charitable founder—viz., The Medical Benevolent Fund Society; and you will be pleased to have it entered under the name and title of "Barrister Freeman's estimate of the value of a medical man's attendance at his court for two days, and at a distance of fifteen Irish miles from his residence, per D. F. Hynes, the medical man in question." Independent of the anxiety I have always felt for the welfare of that charitable society, I could not think of appropriating to my own private use such a sum for my services, as it would be improper of me to accept it for myself, although I have done so for the Medical Benevolent Fund.

This gentleman, who allows a clerk in a bank £2 for the same time, another clerk £1 10*s*., a corporal of dragoons 15*s*., a common broker, and even a policeman of the district, the same sum, gets into a rage when he is asked what he will allow a doctor, who has travelled fifteen miles to his court, and was delayed two days there, and says, "I will only allow 15*s*.; I can't be robbing the ratepayers"—a consideration never dreamt of by "*his worship*" until my case (who pay more rates than all the witnesses put together) came under his notice.

I have entered thus fully into the case to show you and the rest of our brethren, that the sooner we have the general meeting of the profession, alluded to at our last meeting of committee, and establish a "National Medical Defence Association," whose power and influence will be able to wrest from Mr. William Deane Freeman the authority vested in him of thus insulting the members of our profession, the better.

There are other very important matters besides the insult of Barrister Freeman to be looked to, and immediately. Believe me that the interests of our profession require careful watching just now; and I am sure that you will, as you have ever done, be at any time, and at all times, ready to lead us on to the haven of safety and protection.

Awaiting your call, believe me to be, as ever, faithfully yours, D. F. Hynes.

Kinvara, Jan. 10, 1852.

ACTIONS AGAINST SURGEONS BY PATIENTS.

It appears that the practice of bringing actions against medical practitioners for alleged mal-practice has become a prevalent abuse of legal power in the United States. It seems to be a common practice for patients to attempt to recover the fees paid in sickness, with interest, from the doctor, after recovery, by law persecution, and here is an example of it:—

Prosecution for Mal-practice.—A case has recently been tried in the Court of Common Pleas, in the city of Lowell, of a character similar to those mischievous prosecutions that for some years past have alarmed medical gentlemen, in various parts of the country, to such a degree that many have about concluded to let all surgical patients go unassisted in their afflictions. If by any combination of unforeseen constitutional or other circumstances, a fractured bone or punctured wound is not immediately cured, the surgeon is at once driven to the wall by a prosecution for mal practice, the object and aim of the prosecutors being to make to themselves mammon out of the spoils, even if they rob the practitioner of his honest earnings and ruin his reputation. It seems that, in the case alluded to, a woman cut her right thumb while paring apples. In consequence of the condition of the wound, which pained her, Dr. Leach, of that city, was called in for advice. From a careful analysis of the testimony in regard to the treatment, his course appears to have been perfectly judicious, and this was the opinion of very eminent medical gentlemen who were called before the court. Notwithstanding the weight of evidence would seem to have been strong enough to have sustained Dr. Leach, to our surprise, at least, the jury could not agree. The more we have reflected upon the testimony, the more we are astonished at the result. Of what value is evidence in courts of law, if it is to have no weight? Dr. Charles A. Savory, Dr. Mowe, Dr. Thurston, Dr. Dalton, Dr. Green, Dr. Parkman, and Dr. Balch, if we understand them, sustained Dr. Leach triumphantly. At the Missionary Hospital, in China, in which Dr. P. Parker, the American surgeon, has distinguished himself by the performance of some of the boldest operations in surgery, before the people became enlightened and comprehended the value of his services he refused to operate till a bond had been executed, in which applicants agreed not to claim damages of him, should he be unsuccessful. It would perhaps be the course of prudence for surgeons among us to keep blank bonds on hand, to be filled up before commencing treatment, if the public continue to ask for their best endeavours and then prosecute them for damages should the result be unsuccessful.—*Boston Med. and Sur. Jour.*

CLAIMS OF PRESENT DISPENSARY SURGEONS ON NEW DISPENSARIES.

That the present Surgeons of Dispensaries have a prior claim to new appointments cannot, and we believe, is not denied; but cases may arise in which they may not be able practically to assert that claim successfully. A power is given to the Commissioners to interfere, and to them our correspondent must apply if he entertains no doubt as to the intentions of the committee; but he must make out a strong case to induce the Commissioners to exercise the power given them:—

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—Having observed your willingness to give every information respecting the Medical Charities' Bill I am induced to bring my case before you. I have been for nearly three years one of the medical officers to a large dispensary district, which the guardians, in severing the union into districts, have so curtailed that one man can now do the duty of it; they at the same time formed a new district, a great part of which new district belongs to the dispensary to which I am attached, and at present doing the duty. Now, as the principal ratepayers likely to be on the committee of management are determined to elect a friend of theirs from an adjoining union, I would wish to know if the law has any way provided for my appointment to this new district; if so, I would be glad to hear how I am to act? By informing me through the medium of the Press you will greatly oblige

January 15, 1852. A Subscriber.

THE "CURE" OF CATARACT BY LOCAL APPLICATIONS.

Dr. Lebert stated, a short time ago, before the Surgical Society of Paris, that he had no faith in certain ammoniacal preparations which had been supposed capable of producing resolution in cases of incipient cataract. He examined crystalline lenses somewhat altered in structure, and found very

important changes. In hard cataract, for instance, there was an opaque, granular substance interposed between the lamellæ of the lens; this substance is beyond the action of the absorbents, as the lamellæ themselves are horny and atrophied. In soft cataract there is seen in the crystalline cells an effusion of a milky fluid, and in this fluid crystals of cholesterine can be distinguished, the lamellæ being at the same time softened and hypertrophied. None but a surgical treatment can in such cases be followed by a successful result. It was shown during the discussion that those cases which were benefited by Gondret's ammoniacal ointment, were not cases of incipient cataract, but instances of an early stage of amaurosis.

To restore the perfect organization of the crystalline lens when destroyed by disease is impossible; to promise to do so is another affair. If a man does this, he had better rub the eye or the temple with something, and take the patient's money; leaving him to see what he shall see in the sequel. "*Si populus vult decipi decipiatur.*"

MALTREATMENT OF NAVY SURGEONS.

Any one conversant with the feeling of the Admiralty towards naval medical men, must admit, that for the assistant-surgeons now afloat to accept the insulting half-measure from the authorities, is in time to relinquish, *in toto*, their right, by vote of parliament of 1850, to ward-room privileges. Every thing now given these officers is not considered by the Admiralty an established and permanent right!—it is doled out to them as a *placebo*, to deceive the public, and to lull public suspicion! The only remedy for this state of things is an immediate campaign through parliament, the press, and the national medical colleges, for justice from the authorities. The late Mr. Butler of her Majesty's brig-of-war Arab, and the late Mr. Duncan of her Majesty's brig-of-war Persian, both naval assistant-surgeons, have died of fever within the last three years, contracted from fever cases of their respective ships—the former officer in China, the latter officer in the West Indies. Mr. Butler had for some time to relinquish his hammock at four a.m., that it might be lashed up and taken on the upper deck. In each of these brigs-of-war there was a spare cabin. It is said Mr. Butler occupied it in the Arab for some time; but at the caprice of Commander Morris he was suddenly deprived of this accommodation. In the case of the Persian, which ship is now in commission, but under another commander—and an agreeable change for all on board—the present assistant-surgeon has a cabin. Commander Bulman, who invalided from the command of the Persian, was not popular with the junior medical department, and did every thing he could to keep the assistant-surgeon from a cabin! Shame!—shame! Your readers will recollect that Admiral Berkeley has stated in the House of Commons, that it "was totally impossible to provide these young men with cabins in brigs-of-war;" and after such a statement from a member of the legislature, a flag officer of the British navy, and a lord of the Admiralty, there is but one opinion of such a man's veracity. To impose on the House of Commons is a breach of the privileges of that house, and wherefore is it tolerated? The last three years have witnessed important changes as respects the feeling of parliament towards army and naval medical men, and an able editorial article appeared in the *Times* of the 23rd of June, 1849, in advocacy of the military Order of the Bath, and of ward-room privileges for naval assistant-surgeons. Since that period, a majority of eight in parliament has decided, on the motion of Captain Boldero—"That the accommodation provided for the assistant-surgeons on board her Majesty's ships-of-war is inadequate and insufficient for securing the full benefit of their professional service;"—which vote is evaded by the Admiralty. The stringent and decided expressions of an order in council of 1805, are violated for more than forty-five years. The conduct of successive Boards of Admiralty has been inconsistent with their duty to their sovereign's commands. They refuse to recognize the sacred obligations of an order in council, or a vote and censure of parliament, and in their circular respecting naval assistant-surgeons they practically and effectually evade the vote of the Commons of 1850. They blow "hot and cold," and thus sanction contradictions and anomalies. Naval assistant-surgeons, be firm without display! Be energetic and untiring in quiet agitation for a cabin, a servant, a seat at the lieutenant's table, two epaulettes, and a higher rate of half and full pay!—*Letter in Lancet.*

MEDICAL INTELLIGENCE FROM ROSCOMMON.

Interesting Case.—The subject of the present memoranda (Maria D——) was, in the early part of last year, married to a young man in the county Roscommon, Ireland; she being at the time resident with a family in the neighbourhood. Two or three months after her marriage she afforded symptoms of gestation About this time a practical joke was played on her by a waggish friend, who by way of working on her fears, threw at her a newly-killed hare. She was of rather a nervous and excitable temperament, and became so firmly impressed with the idea that the yet unborn offspring would be injured by the transaction, that she sunk for a time into a sort of hypochrondriac state. Her temper, which, previous to the event, had been very easily roused, now became particularly combustible, more especially towards the practiser of the experiment. Her monomania also took an extraordinary turn, in the shape of a rooted antipathy towards dogs—in particular, a white terrier and brown spaniel belonging to the house. It was with the greatest difficulty that she could be restrained within bounds whenever these dogs made their appearance. This may be in some degree accounted for by the fact of the animals in question being owned by the author of her present imbecile state. She by degrees calmed down, and in the middle of last month was safely delivered of a female child, which, extraordinary to say, was impressed on the temple by the outline of a *miniature hare*. This remarkable appearance is most distinctly developed, its situation being slightly over the left eye. The *length* of the object is about two inches, but in all probability it will increase as the head of the child becomes more enlarged. Its colour is not very deep, but is quite readily distinguishable from the skin, while the outline of the form is an exact miniature representation of nature, to the minutest particulars. Up to this time, both mother and child are doing well.—*Lancet.*

FATAL CASE OF TETANUS FOLLOWING THE LIGATURE OF HÆMORRHOIDS.

By James Bolton, M.D.

M. C., coloured female, aged 35, married. Has suffered intensely from piles since the birth of her first child, fifteen years since.

October 6th. A mass of about the size of a hen's egg protrudes from the anus, and separates the nates.

Operation.—The patient was fully anæstheticized. The mass was so vascular that merely sponging with cold water caused the loss of about half a pint of blood in a few minutes. It was divided by sulci into three tumours. A needle was passed through the base of each, carrying a double ligature, which was tied on both sides of the tumour. In forty-eight hours nearly the whole had sloughed off. Chlorine wash was applied to correct the fœtor and to promote healthy action. 4th. A moderate dose of sulphur and bitartrate of potash was ordered to remove constipation caused by opium used to allay the pain which was produced by the ligatures. About three or four times the quantity ordered was given, and produced violent hypercatharsis. This was not checked until it had lasted several days, owing to neglect of directions. 11th. The patient felt remarkably well until night, when she suffered from cramps of the hams. 12th. There were symptoms of decided tetanus. Ordered morphiæ sulph. gr. ss.; quinine disulph. gr. x, every second hour. Chloroform to be used as often as necessary to subdue spasm. Direction not attended to until night. Observing some fœtor from the anus, applied injection of strong solution of nitrate of silver. 13th. Spasms continue when free from the influence of chloroform; some tendency to sink; inability to swallow; directed mercurial inunction extensively. After relaxing the patient completely by chloroform, passed a stomach tube and injected morphiæ sulph. gr. i.; quinine sulphate ʒi, and brandy oss. Only one spasm occurred after this, but the patient continued to sink, and died without a struggle in about four hours. A post-mortem examination was not permitted.

Remarks.—Up to the time that hypercatharsis was produced, the patient was doing very well. Pain had ceased and the appetite and spirits were good. From that time pain returned, accompanied by physical and mental depression. It is therefore highly probable that the irritation of the part, together with general exhaustion, which no doubt caused the tetanus, was really due to the improper administration of medicine to the patient, already in a critical condition from the operation.—*Stethoscope, Virginia, United States.*

PARALYSIS OF THE VELUM PALATI IN CHILDREN.

MM. Trouseau and Lasègne, in the *Union Médicale* for 7th October, 1851, refer to an affection, rather frequent in children, which at first gives the idea of fissure of the palate; which deformity, however, is discovered, on inspection, not to exist. The most prominent symptom is, that the child speaks through its nose. The origin of the affection is sometimes referrible to a violent attack of angina, sometimes to an indisposition in which the child has had difficulty in swallowing, and sometimes to an insignificant indisposition, in which no local pain has been complained of. On examination, the mucous membrane of the pharynx is often found to present traces of recent inflammation, and the tonsils are sometimes enlarged. But, especially, the *velum palati is dependent*, and closes the back of the throat; and, in place of moving up and down, it remains fixed, or nearly so. Hence, the voice passes almost entirely through the nose; liquids also, when taken into the mouth, escape in part through the nostrils. The paralysis here spoken of, is not that of muscles in a state of inflammatory engorgement, nor is it voluntary paralysis from pain. Acute rheumatism is sometimes followed by paralysis, after all pain has ceased, and deep-seated inflammation of the limbs is sometimes followed by the same results. We can hence understand how the velum palati may become paralysed after abscesses have been formed in it. The paralysis of the closing muscles of the larynx, often following tracheotomy, performed on account of croup, appears also referrible to the same cause as the paralysis of the velum palati—an attack of inflammation. The affection generally disappears in from a few days to three weeks, without any treatment; if not, it is soon overcome by a few applications of a strong solution of nitrate of silver, or weak ammonia. Sometimes the paralysis will not be of such simple origin; but, from the presence of strabismus, pains in the head, &c., will rather be an indication of cerebral disease. In *L'Union Médicale* for October 23, Dr. Morisseau of La Flèche, communicates some observations confirmatory of the above observations; but he states that he has observed the disease most frequently in adults.—*London Jour. of Med.*

A HORN DEVELOPED UPON THE HEAD OF A WOMAN.

Described by A. L. Sands, M.D., of Cold Spring, N. Y.

In the spring of 1851, I was called to see Mrs. W——, aged 50 years. She had always enjoyed good health, and was naturally of a full habit. She informed me that she had a "horn" on the back of her head, which had caused her much trouble and uneasiness for a long time, owing to which circumstance she desired its removal. On removing the covering, which she kept continually over it, a fine specimen of ichthyosis cornea, of sixteen years' growth, was at once brought into view. On inspection, it was found to arise from, or rather immediately over, the occipital protuberance, and to extend downwards and backwards about four inches, and then curling upon itself, terminating in a rough sulcated extremity. On handling it, it was found to be very hard, solid, and, when struck with the handle of a scalpel, gave a sharp clear sound; its attachments to the occiput did not appear to be very firm, as they allowed slight motion. Seeing no difficulty in the way of its im mediate removal, an eliptical incision was made on each side of it through the integuments down to the periosteum, and then slipping the scalpel between the base of the horn and the bone, it was easily removed. There was little hæmorrhage, and the wound healed kindly by first intention.

On examination after removal, the horn was found to measure *six and three quarter* inches in length, and *three* inches in circumference at the base.

One very interesting point in the process of this case may be found in the history which she gave of the treatment which had been pursued in order to obtain relief. When first perceived, it felt like a shot underneath the integuments; after some time it made its appearance on the surface of the skin, and several times she picked it off, but after awhile it became so firm that she was obliged to allow it to remain. She took no notice of it for some time, but becoming so large as to interfere with the proper adjustment of her cap, and obliging her to raise her head from the pillow at night whenever she wished to turn over in bed, while it also incommoded her from reposing upon her back, she was necessitated to apply to her family physician (a homœopath) for relief, who promised her that in the space of a short time he would be enabled to remove the difficulty by the use of sundry small white pills which he proceeded to furnish her with; while at the same time he assured her that he had treated successfully, to a cure, several similar cases within the past year in his own practice. For five years she continued to use the homœopath's pills, but still the *horn* remained—still the horn continued to grow. In view of this condition of affairs her faith began to falter, but for some time it was supported with the assurance of her physician that the only reason that the cure had not been effected was, "that he had not as yet got hold of the right pills." Reassured by this assertion, which was repeated from time to time, she kept on until the spring of the present year, when she consulted me, and finally submitted to its removal by the knife.—*New York Jour. of Med.*

PARALYSIS TREATED BY ERGOT OF RYE.

The following are three instances, related by M. Gérard, physician to the Hôtel Dieu, Marseilles, in support of the efficacy of ergot of rye in doses of from half a gramme (7¾ grains) to two-and-a-half grammes (38½ grains) in paralysis of the lower limbs.

Case 1.—A miner, aged 39, of strong constitution, after having worked for some time in a damp situation, was attacked with paraplegia. The paralysis was complete during eighteen months, being accompanied with incontinence of urine; but it then diminished so far as to enable the patient to walk a few steps with the aid of a stick, although with dragging of the limbs, and irregular gait. The affection had lasted four years, and the treatment had been various. On January 2, half a gramme of ergot was administered, and the dose was daily increased to two-and-a half grammes. In the course of February there was marked improvement. On March 15, the patient walked to the bath without aid. Towards the end of April, the incontinence of urine had diminished, and on May 31, he was dismissed, cured.

Case 2.—A man, aged 29, addicted to spiritous liquors, had trembling, with incomplete paralysis anæsthesia of the lower limbs. He recovered under the same treatment in two months.

Case 3.—A man, aged 23, had been exposed in Algeria to damp during four days; this was followed by fever and delirium, which lasted for a fortnight. During convalescence, he found that he had paralysis of the right arm; when the limb recovered, the right leg became affected, and then the left. He had paralysis, with incomplete loss of cutaneous sensibility, in both thighs. After various modes of treatment had been tried in vain for three months, ergot was given in the same doses as above-mentioned. In twenty-nine days, there was great improvement, and the cure was complete in three months.—*Bulletin Général de Thérapeutique*, and *London Jour of Med.*

Glandered Horses.—An unfortunate man in the north of Ireland last week purchased, at a low figure, a glandered horse, which he brought home and cleaned down. The following day the man was seized with glanders, of which he died in the greatest agony. This is another proof of the great necessity there is for some act rendering it imperative to destroy instantly all horses affected with that foul and fatal disease.

SUCCESSFUL REMOVAL OF THE PAROTID GLAND.

By A. J. Wedderburn, M.D.,
Professor of Anatomy in the University of Louisiana.

Calvin, a negro man, aged 23, was admitted into the Circus-street Hospital, New Orleans, on the 24th March, 1851, with a large tumour, extending from the zygoma to the inferior border of the lower jaw, with a very considerable elevation, and occupying a space in an anterior direction beyond the border of the masseter muscle, and extending so far backwards as to separate completely the folds of skin forming the lobes of the ear, and by its base to cover a considerable portion of the anterior border of the sterno-mastoid muscle, near its attachment to the mastoid process. This tumour was medullary in its character; had existed near two years; had been punctured about six months before he was brought to the hospital. The puncture soon closed; considerable enlargement was he consequence, and at the time of the operation, the distension was so great as to produce a degree of attenuation of the skin, rendering the removal of a considerable portion of it necessary. The skin and cellular tissue were in fact so completely united over the summit of the tumour as to form the only covering of this part of the gland, which was fluctuating. The signs indicating disease of the parotid were the anatomical relations of the tumour, confirmed by the escape of purulent matter mixed with blood, through the duct, into the mouth, whenever external pressure was made.

Operation.—An ellipsis, including about an inch and a half of integuments, extending from the zygoma to one and a-half inches below the lower jaw. The integuments were then dissected from the entire surface of the tumour, the parotid duct divided, and the gland raised from its position over the masseter muscle. The dissection was then conducted carefully from below upwards. Upon exposing the carotid artery, where it penetrates the gland, a ligature was placed upon it, and its division effected. Continuing the dissection with more rapidity towards the upper part of the deep cavity, the bed of the gland, between the ramus of the jaw and the temporal bone, and the removal entirely completed, bringing clearly into view the styloid process, with its muscles, the stylo-maxillary ligament, and the posterior border of the internal pterygoid muscle. Two ligatures were applied on small arteries—the usual dressings were used, and in the course of seven weeks the case was discharged as entirely cured. The description of the mode of this operation, and the anatomical relations of the diseased part have been entered into more minutely in consequence of the doubts entertained by some distinguished surgeous concerning the entire removal of the parotid artery gland, and again from the gratification of being enabled to add one more case to the many recorded, proving its practicability.—*New Orleans Monthly Med. Regs.*

HYDRASTIS CANADENSIS IN GONORRHŒA.

By D. M. McCann of Ohio.

As it has for its object the diffusion of knowledge advantageous to the medical profession, permit me to call the attention of the profession through the columns of your excellent journal, to the use of Hydrastis Canadensis (yellow or orange root) in gonorrhœa. I am not aware that any of my brethren have used it in this affection, before myself. My experience, however, in the administration of it, though not extensive, is yet sufficient to warrant me in soliciting a trial of it by those having more opportunity of testing its curative powers than I have. I have used it in several cases in various stages of the disroder, and in *every case* with the most satisfactory results; more especially with males than females. I was led to its use by noticing its well-known sanative properties over inflammations of mucus and epithelial structures, such as aphthæ of the mouth, &c. The ardor urinæ, and the discharge of mucus, has been entirely suspended in every case in from twenty-four to seventy-two hours. In some cases I used the balsam copaiba, in others injections of infusion of the hydrastis alone, but without the same results—a perfect and *permanent* eradication of the disorder. I have varied the strength to suit the case in its different stages, but as a general rule I have used about one drachm of the dried root to the pint of infusion—injecting a syringe full three or four times a day. I hope that some of the profession will give this article a fair trial.—*Ohio Med. and Surg. Jour.*

TREPHINING IN CARIES OF BONES.

M. J. Roux of Toulon, has published an article on trephining in cases of caries, in the *Union Médicale*. His object is not to bring forward the operation as novel, but to cause more attention to be paid to it. The two conditions which he considers indispensable to success are:—1, that the trephine, and other instruments employed, should be capable of removing the whole diseased portion, and even going beyond it; 2, that the patient should be placed under such hygienic and therapeutic conditions as are most likely to prevent a return of the disease. He relates cases of the following descriptions, in which he has operated with the trephine: caries of the petrous portion of the temporal bone; of the anterior wall of the right superior maxilla; of the sternum (two cases); of the malar bone; of the left tibia; of the right tibia (two cases); of the os calcis; and of the great trochanter. Of the eleven patients operated on, eight recovered, two died from scrofulous cachexia, and one from the operation not having been perfectly performed. M. Roux considers the proceeding safe, and eminently calculated to preserve the remaining sound part of the bone.—*London Med. Jour.*

TRICKS OF ADVERTISERS.

The following advertisement having appeared in the *Critic*:

"A speedy cure for Stone and Gravel will be sent to any person by inclosing thirteen stamps to Thomas Wilkinson, Land Agent, Gainsborough, Lincolnshire,"

A patient of mine, who is an intelligent gentleman, and one of your subscribers, sent thirteen stamps to Thomas Wilkinson, and received the following reply:—

"Dear Sir,—Your 13 stps are recd beg to say Instead of a Dose of Egyptian Drops, I will send the recipe for 36 stamps more and full directions how to Mix and Take it. Drops will dissolve the Stone and bring it away in Sand Quiet easy speedy cure is certain your respy Thomas Wilkinson, Land Agent."

This reply so much incensed my patient, that he at once intimated to Mr. Wilkinson that he would publicly expose him if he did not give the "speedy cure" *in an available form*, whereupon, in reply, the following evasive epistle was received, which I may state has not induced the invalid to discontinue appropriate treatment:—

"Dr Sir,—Yours is recd. recipe return'd. 1 oz Barbadoes Tar 1 oz Balsom Sulphur 1 oz Linseed oil 1 do. Spirits Turpentine, On receiving the stamps full Directions will be returned. Yours respy Thomas Wilkinson Land Agent."

I need hardly add, that the recipe is nonsense; and even were it a good prescription, the want of directions for its use would render it valueless to a patient. The offer of a cure, therefore, for thirteen stamps cannot arise from a delusion on his part as to the efficacy of his nostrum, and is simply a clever method of obtaining money—*not certainly for value received.*—*Dr. J. R. Cormack, M.D., in Lancet.*

Bleeding by Dispensers.—At the late meeting of the Marylebone Board of Guardians, Mr. Beevor alluded to the dangerous practice of dispensers being allowed to bleed, and suggested to Mr. Guilham, the house-surgeon, the propriety of not allowing the dispenser to perform that operation. Mr. Guilham replied, that although the present dispenser had been many years in the house, and had considerable experience, he (Mr. G.) invariably bled both the in and the out patients, when the cases required it. Mr. Jacob Bell, M.P. (chairman), and several other guardians, highly eulogized the experience and skill of the dispenser, and expressed their conviction that there would be no danger in allowing that gentleman to bleed. Mr. Beevor fully coincided in all the praise given to the dispenser, but in principle objected to a person, not being a surgeon, bleeding, because the slightest deviation might lead to a fatal result, and involve them (the guardians) in a very serious charge. Mr. Guilham assured the board that he himself would attend to the bleeding. What is a dispenser?

BRAITHWAITE'S RETROSPECT OF MEDICINE.

Just published, price 6s., Volume Twenty-four of this work,

GIVING a careful Analysis of the most Practical Papers, Lectures, and Transactions of Societies, published in all the Medical Journals within the last Six Months. Appended to which is an Alphabetical List of Diseases; with the most recent Suggestions of Treatment.

Edited by W. BRAITHWAITE, Lecturer on Obstetric Medicine in the Leeds School of Medicine, &c.

*** This Volume contains a General Index to Vols. 21, 22, 23, and 24.

London: Simpkin, Marshall, and Co.; Edinburgh: Oliver and Boyd; Dublin: Hodges and Smith.

Just published, 8vo, pp. 96, price 2s. 6d.,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

THE INFLAMMATIONS OF THE EYEBALL:

The first Session of 1852 commenced on the 15th of January.

LOUTH COUNTY INFIRMARY.

NOTICE is hereby given, that the Governors of the Louth County Infirmary will, on Wednesday, the 28th instant, receive Applications, and proceed to appoint a fit and proper person to fill the Office of Resident Apothecary to that Establishment, at a Salary of £40 per annum, with Apartments and Fuel.

Testimonials, &c., to be lodged with me, on or before Tuesday, the 27th instant.

No appointment will be made for a less period than Twelve Months.

Personal attendance of Candidates will be required.

Signed by Order,
ALEXANDER SHEKLETON, Secretary.

Dundalk, 12th Jan., 1852.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.
☞ *Change of Proprietorship.*
BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *leitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,
of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Dr. JACOB in the chair.

CASE OF ENLARGEMENT OF THE PROSTATE GLAND, THE POSTERIOR EXTREMITY OF THE LEFT LOBE FORMING A REMARKABLE TUMOUR PROJECTING INTO THE BLADDER, AND GIVING RISE TO RETENTION OF URINE; ACCOMPANIED BY HÆMATURIA, AND COMPLICATED WITH FALSE PASSAGE; WITH OBSERVATIONS.

By JOHN H. POWER, M.D., F.R.C.S.,
One of the Surgeons of Jervis-street Hospital, and Professor of Practical Anatomy in the Royal College of Surgeons.

DR. POWER said he wished to submit, for the consideration of the Society, a specimen of diseased prostate gland, accompanied, during the lifetime of the patient, by retention of urine and hæmaturia. The subject of this affection was a person named Thomas Murray, aged about 63 years; he was admitted into Jervis street Infirmary on the 1st of November, 1851. At the time of his admission he was suffering from retention of urine and distension of the bladder, accompanied by hæmorrhage from the urethra. He also complained of considerable pain in the region of the neck of the bladder, extending forward along the line of the urethra, and which was increased whenever he attempted to make water. On examining the abdomen, a tumour, situated above the pubis, was distinctly perceptible. The pulse was small and rapid, the tongue dry and furred, and the skin hot. The patient stated that, for some years previously, he was tormented by frequent inclinations to void urine, which at last amounted to an incontinence; and for some months prior to his admission he was obliged to pass water as often as ten or twenty times in the twenty-four hours. All the foregoing symptoms were aggravated by sexual indulgence, committed a short time before he presented himself at the hospital. He had long been addicted to the abuse of ardent spirits, and his occupation exposed him to sudden changes of temperature. On various occasions during the preceding year, he passed small quantities of blood from the urethra, but he was not able to recollect having received any injury to which this occurrence might be attributed. The symptoms becoming every day more and more distressing, he sought the advice of a professional gentleman, who, though he afforded him some relief, used a considerable degree of violence in passing the catheter. On that occasion, some urine was drawn off, but the patient stated that he afterwards experienced very severe pain about the region of the neck of the bladder, accompanied with a considerable discharge of blood from the urethra. When he was admitted into hospital, the retention of urine was most distressing; and Mr. Dempster, the resident pupil, attempted, with the greatest caution, to introduce a full-sized prostatic catheter. At first his efforts were attended with some difficulty, but at length, by passing his finger into the rectum, and thus tilting up the point of the instrument, he succeeded in getting it into the bladder. A large quantity of dark bloody urine was thus drawn off, but the relief obtained thereby was only of temporary duration, for the instrument had to be introduced again at the end of about three hours, when urine of the same description was again drawn off. As he appeared a good deal exhausted, and suffered considerable uneasiness after the introduction of the catheter, he was ordered a draught composed of camphor mixture and tincture of opium. In the hope that by the administration of remedies internally, the hæmorrhage might be restrained, he was ordered a mixture composed of tannic acid with the infusion and tincture of buchu. Some degree of improvement appeared to attend this treatment, for the urine which, at the first introduction of the catheter, was of a reddish-brown colour, and of a fœtid odour, became of a much lighter and more natural hue, and acquired a less disagreeable smell. The improvement, however, was but of short duration; the retention again occurred, accompanied with great uneasiness. The catheter was again introduced, but, as usual, with difficulty. The constitutional symptoms underwent no improvement; a low muttering delirium speedily set in; the surface of the body became cold; the tongue appeared loaded with a brown crust; pulse became feeble and intermittent; and finally, the patient died comatose, on the fourth day after his admission.

On examination of the body after death, attention was directed in the first instance to the state of the bladder. The size of this organ was much increased, and its coats considerably thickened; and on examining the interior, the mucous membrane was found greatly corrugated, forming permanent folds throughout its entire extent. The appearance of the membrane closely resembled the "columnæ carneæ" of the heart, both in appearance and in structure; for it might be easily seen that these hypertrophied folds were formed not merely by mucous membrane, but by strong bands of muscular fibre. These remarkable appearances of the bladder had been compared to the ventricles of the heart. Between these columns, several small pouches might be distinctly seen. When an instrument was introduced into these cavities, they were found to lead outwards towards the external surface of the bladder. Some of the pouches were much larger than others, and at the bottom of these cavities the coats of the organ were much thinner than in other situations. Following up the analogy already alluded to, we would say that the abnormal condition of the bladder in this disease might also be considered as bearing a strong resemblance to the diseased condition of the heart to which the term "eccentric hypertrophy" has been applied—an increase in the capacity of the cavities, and, at the same time, a thickening of their coats. The cavity of the bladder was dilated to such an extent as to be capable of containing during the lifetime of the patient at least a quart of urine, though it subsequently contracted to such dimensions after death as to be capable of holding little more than six or eight ounces only. On making further examination, two strong prominent cords were found, running down and terminating at the neck of the bladder. These cords were "Bell's muscles" at the orifice of the ureters, greatly increased in size. Both from the specimen before the Society, and from repeated observation in similar cases, it would appear that, as a general rule, the muscular tunic of the bladder in chronic enlargement of the prostate gland was greatly hypertrophied.

On proceeding with the examination, it was found that an enlargement of both lateral lobes of the prostate gland existed. This enlargement was well marked, both above and below the urethra. When the finger was introduced into the rectum, the lateral lobes of the gland could be easily felt as forming a tumour in that situation. There was also a very remarkable enlargement of the posterior portion of the left lateral lobe, projecting into the bladder, and encroaching on the situation occupied by the third or Home's lobe; this latter lobe, however, was not so much increased in size as to be at all likely to give rise to the retention of urine under which the patient laboured. It appeared quite evident that this distressing symptom depended on the very great enlargement of the posterior extremity of the left lobe. This enlargement of the posterior extremity of one of the lobes of the prostate gland had not escaped the observation of Sir Everard Home, Sir Benjamin Brodie, and Cruveilhier. This peculiar enlargement of the prostate gland would appear to be of rather rare occurrence; and Sir Everard Home in his account of a case which came under his own observation mentions it as such. In the instance which he mentions, the posterior extremity of the left lobe was greatly enlarged, and formed a tumour in the interior of the bladder, by which the middle lobe was thrown over towards the right side. On examining the lining membrane of the bladder, it presented a dark bluish appearance; this alteration in colour he believed was produced by the remarkable turgescence of the veins of the organ; these vessels were swollen to such a degree as to admit of being distinctly traced underneath the mucous membrane. In the intervals between the different columns before mentioned, there was a somewhat reddish or ecchymosed appearance of the lining membrane. This also had been noticed by Cruveilhier. In the case before the Society, he was induced to dwell on the distended condition of the veins of the bladder, from the fact of the patient having suffered from hæmorrhage into the bladder, and having passed from the urethra a quantity of blood before any instrument had been passed into the urethra; so that in the first instance, the hæmorrhage from the bladder must, in all probability, have depended upon an oozing of blood from the distended veins in the interior of the organ. If it were remembered that those veins conveyed the blood from the bladder into the large veins in the interior of the pelvis, through a venous plexus situated close to the prostate between the bladder and the rectum, it was easy to understand how, when this plexus was pressed on by the enlargement of the gland, the veins of the bladder should become enlarged and turgid, as in the present instance. The veins of the bladder were consequently distended. This over-distension of the veins, accompanied by the retention of urine within the bladder, would necessarily give rise to a state of chronic inflammation of the mucous membrane, and thus serve to account for the effusion of blood which took place in similar cases. But doubtless another cause of hæmorrhage, in the case before the Society, arose from the violent manner in which the catheter was introduced before his admission into hospital; for it was worthy of remark that the blood which came away immediately after the instrument had been withdrawn, was of a bright arterial hue, so that the hæmorrhage, in all probability, depended upon the injury which the patient sustained during the introduction of the instrument. According to the patient's own account, the catheter had at that time been introduced in a very forcible manner, and as a matter of course, struck against the most prominent portion of the enlarged prostate gland, and then, instead of being manœuvred into the bladder, in the way subsequently adopted whilst in the hospital, it was pushed onwards with violence, and thus rupturing the lining membrane of the urethra, it found its way by an artificial opening into the substance of the gland.

On making further examination of the parts, it would be observed that the canal of the urethra had undergone a peculiar change of form in consequence of the enlarged condition of the back part of the left lobe of the prostate gland. In this situation it appeared, in fact, to describe a remarkable curve, and to be considerably *larger* in its calibre than it is in the natural condition of the parts. On examining that part of the urethra which was anterior to the prostate gland, no traces of stricture could be detected.

This preparation was, he thought, instructive in more than one point of view. It was interesting, first of all, on account of the hæmorrhage from the bladder which had taken place; 2nd, from the occurrence of the enlargement of the posterior extremity of the left lateral lobe of the prostate gland, and its projection into the bladder, so as to cause retention of urine; and 3rd, in consequence of the false passage made from the urethra into the enlarged portion of the gland.

Dr. Geoghegan had reason to believe that the operation of tapping the bladder above the pubis, and the subsequent maintenance of the artificial opening, might materially prolong life in severe cases of senile enlargement of the prostate, especially when complicated with hæmaturia. This view is supported both by a rational analogy and also by observation. Thus in chronic disease of the larynx, whether syphilitic or otherwise, unequivocal advantage had been derived from the operation of tracheotomy, viewed simply as a means of giving rest to the larynx; and there appears no reason why a similar procedure may not be extended to other organs. In an important case of prostatic enlargement, complicated with hæmorrhage into the bladder, which occurred in his experience two years since, and the subject of which is still alive, the bladder was tapped above the pubis, and he (Dr. G.) directed the patient to wear a straight gum-elastic catheter (about five inches in length) in the fistulous track, and to introduce it into the bladder *only when micturition was required.* By the adoption of this plan, not only have the attacks of bleeding very much diminished in frequency, but also the means have been afforded of applying (as was done in a subsequent hæmorrhage) various astringents directly to

the lining membrane of the bladder without injury to the prostate, and with great ease to the surgeon. Dr. G. had thus introduced Ruspini's styptic and moderately strong solutions of tannic and gallic acids, and iced water; and it is worthy of remark, that none of these produced any irritation. The artificial opening has the additional and important advantage of allowing the bladder to be thoroughly cleansed out at suitable intervals, without pain or inconvenience to the patient, thus averting serious dangers from stagnation of ammoniacal urine in that organ. The accumulation of blood-clots in the bladder by irritating its neck, sometimes gives rise to violent and painful straining. In the case of an old gentleman who induced hæmorrhage into the bladder by an attempt at self-catheterization, Dr. G. succeeded in giving speedy relief by the use of an instrument devised, as he believed, by Sir Philip Crampton, for the extraction of detritus after the operation of lithotrity. This consists of a strong glass bottle well exhausted by a suitable syringe, and connected by a stopcock, with the metallic catheter to be introduced. Amongst various astringents resorted to for the arrest of hæmaturia, Dr. G. was inclined to give a decided preference to Ruspini's styptic, having seen its employment followed by arrest of the bleeding, where gallic acid in full doses appeared to have failed; in some cases, however, astringents of all kinds seem to be inoperative, and the cessation of the bleeding is perhaps spontaneous. Dr. G. had found by examination, that Ruspini's nostrum does not, as alleged, contain gallic acid.

Dr. Benson—What quantity of Ruspini's styptic did you employ?

Dr. Geoghegan—According to my recollection, an ounce every second hour. In one case the bleeding ceased after the second dose.

Dr. Power—My colleague, Mr. James S. Hughes, has employed gallic acid in hæmaturia with favourable results.

Dr. Benson said that he had employed gallic acid in the hæmoptysis of phthisis with advantage, but he had found nothing so valuable as Ruspini's styptic; one of his patients, indeed, was so convinced of its efficacy, that she used when attacked to call for it of her own accord.

CASE IN WHICH THE TRICHINA SPIRALIS EXISTED IN VERY LARGE NUMBER IN THE VOLUNTARY MUSCLES.

By O'B. Bellingham, M.D., F.R.C.S.

Dr. Bellingham said, since the last meeting of the Society he had met with a case where the trichina spiralis existed in very large number in the voluntary muscles, and he would avail himself of there being no more important business before the Society to exhibit specimens to the members, as it was probable that, owing to its rarity, some of those present may not previously have had the opportunity of examining the recent animal. The portions of muscle upon the table contained the cysts *in situ*, and the drawings made by Dr. Carte gave an excellent representation of the cysts and of the animal, magnified 200 diameters. Dr. Carte had likewise kindly prepared some specimens for examination by the microscope in case time permitted.

Bernard McAuley, ætat. 67, a labourer, admitted into St. Vincent's Hospital, December 20, 1851. He had for several years suffered from cough and oppression of his breathing. A fortnight ago he states that he was attacked with severe pain in the left side after exposure to cold. On examination, signs of bronchitis and emphysema of the lungs were evident; in addition, there was dulness over the base of the left lung posteriorly, but not the degree of dulness which indicated much fluid. The breathing was much oppressed, and the patient much debilitated. He gradually became worse, and died on the fifth day after his admission.

On examination, the lungs were emphysematous, the bronchial tubes loaded with mucus, the left pleura was coated with lymph, and about a pint and a half of very fœtid pus was contained in its cavity.

The most remarkable point, however, connected with the case was the presence of an immense number of the cysts of the trichina spiralis in the voluntary muscles, particularly in the pectoralis major and minor upon each side, in the sterno mastoid, sterno-hyoid, sterno-thyroid, and omo-hyoid muscles upon both sides.

When these muscles were exposed, they had the appearance of being dotted over with innumerable minute white specks of an oval or elliptic form, the long diameter corresponding with that of the muscular fibres; these, on examination, proved to be cysts of the trichina spiralis: the cysts were tough, and a single entozoon was coiled up in each. In one instance a cyst contained two of these animals.

This entozoon was first described in the year 1835 by Professor Owen in the Zoological Transactions, under the name "Trichina Spiralis;" subsequently it was very fully examined by Dr. Arthur Farre. Mr. Owen places it in the class Protelmintha, in which it is associated with the spermatozoa and vibrionidæ.

The cyst which encloses the animal is, according to Dr. Farre, double, and he has frequently found two individuals in the same cyst. The entozoon itself is about the 30th of an inch in length, and as the magnified drawings show it has a cylindrical form, and is of a greater diameter at one extremity than the other. Dr. Farre describes an alimentary canal with an orifice at the larger extremity, and an indication of one at the smaller; the latter Mr. Owen regards as the anus.

The usual seat of the cysts containing these entozoa is in the voluntary muscles. Dr. Farre says*: The superficial muscles contain them in far greater numbers than the deeper-seated, especially the broad flat muscles, as the pectoralis major and latissimus dorsi. In a case which he relates, they were present in greater or less numbers, "in all the muscles of the trunk and extremities, in those of the eye and external ear, in the tongue and soft palate, the constrictors of the pharynx, and the œsophagus, both the crura and radiated portion of the diaphragm, in the levator and external sphincter ani, and the muscles of the urethra. The only muscular structures which seemed to be free from them were the heart and muscular envelope of the stomach, intestines, and bladder, together with one or two other exceptions." In the present case these entozoa were not found in either the diaphragm or heart; but they existed in very large numbers in the superficial muscles of the chest and neck.

The presence of these entozoa in the muscles does not appear to have any injurious influence upon the individual who is the subject of them, or to cause any alteration in the muscles themselves. In the subject of this case, the muscles which contained them were remarkably well developed, and had otherwise a very healthy appearance. Their occurrence in the system Mr. Owen states to be unconnected with either age, sex, or any particular disease; they were met with by Mr. Curling† in the muscles of a healthy man whose death was the result of an accident; and they have been found in subjects dying of the most opposite forms of disease.

Dr. Jacob thought the case one of some interest, because it reminded them how very careless they often were in their anatomical and other observations. A good many of those he was addressing could remember that, previous to the discovery of these remarkable animals, they were frequently observed in the dissecting-room, though no one ever had the remotest idea as to their real nature. He could himself recollect seeing some muscles which were very profusely dotted with them; but until Mr. Owen placed them under a microscope, and thus ascertained what they really were, no one had the slightest suspicion about their being living animals.

Dr. Bagot inquired if any theory had been advanced to account for the origin of these entozoa?

Dr. Jacob was inclined to think that their origin was as yet involved in doubt and uncertainty. One thing,

---

* Medical Gazette, December, 1835.

† Medical Gazette, February, 1836.

however, was certain—namely, that not only these entozoa, but others of much greater size, and in much greater quantity, might exist in healthy bodies, without disturbing to any considerable extent the functions of the animal economy.

SURGICAL SOCIETY OF PARIS.

ON CONTRACTIONS AND FISSURES OF THE ANUS.

M Maisonneuve made some observations on the thesis of one of his intern pupils, M. Le Pelletier. In this thesis a great number of cases of cure of contractions and fissures of the anus are accurately noted.

M. Recamier, who first proposed forcible dilatation of the anal opening, confined himself to general facts. He recommended dilatation as a means of remedying contraction or retraction of the muscles, but he had not pointed out the manner of applying this process, and he described the same by a name which very imperfectly conveyed the idea of its action. In the memoir read by this learned doctor before the Academy of Medicine, he gave the name of graduated dilatation to the forcible dilatation of the anus.

M. Maisonneuve, who assisted at the operations performed by M. Recamier, was struck by its importance, and was induced to bring the practice into general use. The experiments which he undertook for the accomplishment of this object are related in the thesis of M. Le Pelletier. The author thus divides the cases in which he has seen dilatation applied with success:—1. Simple constipation. Obstinate constipation in females. 2. Simple constipation without fissure. 3. Contraction complicated with fissure. 4. Contraction complicated with hæmorrhoids. 5. Tenesmus of tropical climates, with the complication of dysentery. M. Le Pelletier has observed cases which can be classed under all these categories. M. Maisonneuve, in terminating, offered his thanks to the author, whose work is concisely written and entirely practical.

M. Lenoir then stated that M. Monod, one of the members of the Society, ought not to be forgotten in the history of this method of treatment, to the publishing and bringing into general use of which, among surgeons, he contributed. M. Lenoir added, that he could not sufficiently regret the species of neglect or oblivion into which so precious a method was allowed to fall. For his part, he had frequently employed it, and always, or nearly always, with success. During the last three months he had occasion to make use of it on a magistrate, who, during five years, had been submitted to various plans of treatment. The sufferings endured by the patient were very severe, especially when he remained standing for a few minutes. There existed round the verge of the anus a great number of little hæmorrhoidal tumours. The operation was, as it always is, most simple, and the cure, so to speak, instantaneous, and which still continues permanent. This operation is, it must be confessed, most painful; therefore the patients ought first to be anæsthetized. But it is necessary to mention that the employment of chloroform presents a slight inconvenience. Under its anæsthetic influence, a relaxation of all the muscles comes on, and as the sphincter ceases to resist, that little pathognomonic snap which indicates that some of the muscular fibres are being torn, is no longer heard. The muscle allows itself to be distended, but does not tear. In such a case, the surgeon will take care to make use of a greater dilating force; in a word, to persevere until the sensation of tearing is perceived. The rupture of the fibres is nearly always followed by ecchymosis. Sometimes the effusion of blood is very considerable, and we have a true bloody tumour. M. Guersant saw, in a case of this kind, the bloody swelling take on inflammatory action and suppuration. M. Lenoir thought that such an accident might be easily prevented by introducing a plug into the anus, and keeping it there for twenty-four or forty-eight hours.

M. Demarquay remarked than in an article published in the *Archives Générales de Médécine* on fissures of the anus, relying on the authority of M. Blandin and M. Jules Guerin, he recommended the submucous division of the sphincter ani in the treatment of fissures of the anus; and he brought forward in that paper a number of cases in support of the doctrines which he defended. Since that, MM. Maisonneuve and Monod have correctly recommended forcible dilatation of the anus for the cure, not only of fissures, but even of contraction of the sphincter. I can understand (said M. Demarquay) that in simple cases this operation is to be preferred to that of Boyer or even to that of Blandin. When the contraction of the sphincter is complicated with considerable hæmorrhoids, which are not inflamed, is forcible dilatation still indicated? I conceive it may still be applicable to these cases, although it exposes the patient infinitely more to the sanguineous effusions to which M. Lenoir has so justly called the attention of the Society; but if these tumours are inflamed, and at the same time strangulated by the contraction of the sphincter, may forcible dilatation still be had recourse to? I think not. Dilatation, in this case, is liable to cause phlegmonous inflammation of the cellular tissue surrounding the anus and the neighbouring parts, or even phlebitis, whilst submucous tenotomy is not attended by this inconvenience. I have seen Blandin operate in this manner under various circumstances with great advantage to the patient, and no ill effects ensued. I have on several occasions followed the precept of Blandin, and it has succeeded well. Very lately I was called on by Dr. Roujon to see a lady affected with contraction of the sphincter and anal fissure. A hæmorrhoidal attack coming on, large tumours formed around the margin of the anus; a certain number of the hæmorrhoidal tumours coming from the cavity of the rectum were strongly grasped by the sphincter; they were in part gangrened, and exhaled a putrid odour. The patient complained of fever, nausea, pain in the fundament shooting up through the pelvis. Direct examination of all the parts was impossible, the pains were so severe. I had an idea of chloroformizing the patient and using dilatation, but I was restrained by the fear of phlegmon ensuing as a consequence of the considerable violence that would be done to all the inflamed parts. I determined, therefore, to put the patient under the influence of chloroform as far only as the sensibility would be blunted, but not sufficiently to cause muscular relaxation. I performed the submucous section; the symptoms quickly ceased, and the day after the operation the patient was in a very satisfactory state. For all these reasons, I would prefer submucous tenotomy in cases of contraction of the sphincter complicated with inflamed hæmorrhoids, which, when properly performed, relieves the symptoms and does not expose the patient, as much as the forcible dilatation, to inflammatory consequences.

M. Michon was astonished, like M. Lenoir, at the little attention bestowed by surgeons to forcible dilatation. It is to be wished that this method may become common. M. Michon has performed it at least thirty times; he has kept the patient in view for as long a time as possible, and has seen but one case of relapse, and he is disposed to consider this relapse as a consequence of the inexperience which he had then in the application of this process. Twice he has operated on patients who had been formerly operated on by Blandin, and who had suffered a relapse; he succeeded immediately. With regard to the consecutive ecchymosis, it is slight and diffused. He has never seen it give rise to abscess. Amongst those operated on, M. Michon remarked one suffering from tenesmus and dysentery, acquired in tropical climates. The operation cured both the tenesmus and the dysentery. What cannot be too well remarked with regard to this process, is the rapid manner in which a cure is obtained. The patient awakes cured. M. Michon deprecates the use of the plug proposed by M. Lenoir as a means of completing the treatment. He finds this addition painful and useless. With regard to the remarks made by M. Lenoir, as to the sensations which the surgeon feels during the operation, he thinks the most frequent is the sensation of tearing; but it is by no means constant. There is besides for our guidance a very simple means furnished by the anatomical disposition of the parts. We meet the natural boundaries which regu-

late the dilating force we are to apply. On each side we meet the tuberosities of the ischia, and anteriorly and posteriorly we are stopped by the pubis and coccyx. As to the cases regarded by M. Demarquay as requiring a different method of treatment, they must be divided. If the hæmorrhoids are caused by the contraction of the sphincter, we may dilate fearlessly. The hæmorrhoids will not be contra-indications. But if the hæmorrhoids constitute the principal disease, and there is strangulation and mortification of the hæmorrhoidal tumours, then the contraction is a complication. In these cases we may perhaps resort to submucous tenotomy; but it will be better to wait the subsidence of the inflammatory attack and then operate by dilatation.—*Presse Médicale.*

MEDICAL SOCIETY OF LONDON.

A communication was read from Mr. WARDROP, entitled,

ON THE BENEFITS THAT MAY BE DERIVED FROM PLACING MEDICINAL SUBSTANCES UPON THE TONGUE INSTEAD OF INTO THE STOMACH.

In a practical science like that of medicine, an insulated fact often forms a connecting link with other facts that had appeared equally unimportant. The medical observer does well to collect such facts, and it is one not of the least advantages of societies, that they stimulate members of the profession to record observations which might not have been deemed of sufficient importance to be brought before the public in any other channel. With such an impression, I venture, on the present occasion, to call the attention of my fellow-members to a subject which seems to be worthy of their consideration, and which has not hitherto, as far as I know, claimed much attention. There are many circumstances which might be mentioned, in order to show the influence which some medicinal substances have on the animal economy when they are placed upon the surface of the tongue, these effects being caused by the absorption of the medicine, and its subsequent admixture with the mass of blood. Such phenomena are quite analogous to the effects produced by mercury or arsenic, whether these pass into the blood by the pulmonary, by the cutaneous, or by the absorbents of the alimentary canal. A gentleman, subject to what are usually called bilious headaches, had, during many years, seldom failed to obtain relief by taking sometimes two, and sometimes only one grain of calomel. He repeatedly found that there was a distinct difference in the length of time which the calomel took to relieve the headache, according as it was taken in the form of a powder put upon the tongue, or of a pill taken into the stomach. Another gentleman who had for many years suffered from dyspepsia, and who, for some years before I saw him, was in the habit of regulating his bowels by taking a pill composed of a couple of grains of aloes with myrrh, accidentally discovered that there was a remarkable difference in the effect of the pill when swallowed or when allowed to dissolve in the mouth. When taken into the stomach, it always created a good deal of pain in the whole course of the alimentary canal, and the evacuations were irregular both in number and in quantity; but when the pill was dissolved in the mouth, no other sensible effect was ever produced than one natural evacuation. Further experience convinced me of the difference in the efficacy of medicines placed upon the tongue, or taken into the stomach, and led me to inquire into the cause, and endeavour to explain so important a phenomena. The structure of the tongue pointed out that it possesses an abundant supply of absorbents. "The spirituous parts," observes the illustrious Haller, "more especially of vegetables, are received either into the papillæ themselves, or into the absorbing villa of the tongue; as appears from the speedy renovation of strength by liquors of this kind even when they are not taken into the stomach." This structure satisfactorily explains how medicinal bodies, when placed upon the tongue, are absorbed and carried directly by the absorbent vessels of that organ into the venous circulation; whereas, when the same substances are taken into the stomach they are necessarily mixed with the food and juices contained in the alimentary canal, so that a more lengthened period must be required to separate them, and convey them by the absorbents into the thoracic duct, and thence into the venous system. Or they may pass unchanged, as has often been observed, out of the stomach, and in this unaltered state, they are evacuated along with the excretions from the alimentary canal. This remarkable effect of medicines when placed upon the tongue, is strikingly illustrated in the administration of calomel, and it will be found that placing a very small quantity of it, say the sixth or even the twelfth part of a grain at short intervals, upon the tongue, such as every half hour, the mineral is rapidly absorbed, and ptyalism more quickly produced than by any other mode of employing the calomel. These results of medicines, I may also observe, are well known by the effects which croton oil produces when applied to the tongue; and it is by no means improbable that the good effects of some medicines, when used in the form of lozenges, may be attributed to their absorption by the vessels of the tongue. All the circumstances regarding the difference and the effects of medicinal bodies, when conveyed to the venous system directly by the vessels of the tongue, or when they reach the blood by the more uncertain and circuitous course by the absorbents of the alimentary canal, appear to be worthy of being noticed, and may, it is not too much to hope, lead to some practical improvement in the mode of administering remedies. How far such differences will be found to result from exhibiting chloroform, the hydrocyanic acid, and the sulphates of quinine, iron, copper, and zinc, in the form of lozenges, and the advantages of using these medicines in such a manner, well merits further inquiry.

ULCER OF THE STOMACH.

Dr. ROUTH exhibited the stomach, part of the uterus, and left ovary of a patient, aged 33, unmarried, who had died from profuse hæmatemesis. She had been under his care two years back, but had frequently been an inmate in more than one metropolitan hospital during an illness extending over a period of seven years, off and on. When seen by Dr. Routh, her symptoms were those of marked gastrodynia, only that the acute pain referred to the left sub-mammary region was relieved by *cold*, increased by *warm* drinks. Coupling the last circumstance with the fact, that on two previous occasions she had suffered from hæmatemesis and melæna, he had diagnosed an ulcer of the stomach. There was also copious leucorrhœa, and pain in the back, which had led him to suspect uterine disease, but she had objected to an examination. He had prescribed the usual remedies, but with little amendment. She had subsequently been under Dr. Hare's care, at the Welbeck-street Dispensary, who had confirmed his diagnosis. She continued sometimes better, sometimes worse, till within a week back, when she was seized with profuse hæmatemesis. Mr. Adams then attended her, but she died within a few days. The post-mortem examination was made two days after death by Dr. Taylor. The heart was healthy; the lungs also, except the apex of the right lung, where there was evidence of an old tubercular affection, the apex being puckered; on cutting into which a small, perfectly healthy-looking cavity, lined by mucous membrane, about the size of a pea, was exposed. The lining membrane of the stomach towards the pylorus was much congested and stained. In the lesser cul de sac, about two inches from the cardiac orifice, was a small aperture, about the size of a shilling, excavated, looking as if a piece of mucous membrane had been punched out, in the centre of which was a small aperture about the size of a pin's head, opening directly in the artery. The stomach was half full of grumous, black blood. The uterine cavity was rather larger than natural, with a small clot within it; and attached to the left side of it by a pedicle, close to the Fallopian aperture, was a small polypus, about the size of a haricot bean, very red and firm. Both the ovaries were diseased. Several Graafian vesicles were enlarged, and there were several cysts.

In the left ovary, near the surface, there was a dark, gangrenous-looking cavity (free from odour, however), large enough to contain a pea; it was bounded by a firm capsule. The kidneys were large; the other viscera healthy. At different times in her illness this patient had been much emaciated, so as to lead to the suspicion that phthisis coexisted; but at the period of her death, excepting in the size of the breasts, which were shrivelled up, she was tolerably *embonpoint*. The catamenia had been occasionally profuse, but she had been regular up to a fortnight before death.

Mr. Hancock read a paper

ON THE EXCISION OF DISEASED JOINTS.

He commenced by giving the account of three cases in which he had performed the operation of excision—one at the shoulder, a second at the elbow, and the third at the ankle joint—abstracts of which have already appeared in our "Mirror of Surgery." He next alluded to the objections which have been urged against the operation for excision of joints—viz., extreme suppuration—the formation of sinuses, and consequent difficulty of healing, with constitutional disturbance—the shock to the patient—and, lastly, those recently adduced by Mr. Gay—the inutility of the operation, and its unphilosophical character as a mode of operation for diseased joints. Mr. Hancock alleges that the degree of suppuration does not influence the patient so much as the character of the discharge. A patient with diseased joint, discharging but little, but that little of a morbid and unhealthy character, will suffer from extreme constitutional disturbance: he will become emaciated, lose strength, and be reduced almost to the verge of the grave. Operate upon this joint, remove the diseased parts, and let the subsequent discharge be ever so profuse, so long as it is not actually of a morbid character, and the constitutional symptoms will subside, the patient will gradually acquire strength and flesh, whilst the improvement in the character of the discharge marks the gradual progress towards recovery: that this is accounted for when we consider, that in the one instance there is a morbid action going on in diseased structures, producing unhealthy discharge, whilst in the other the process is one of reparation, proceeding in healthy parts, and giving rise to healthy though profuse discharge; that sinuses do not form so readily after these operations as has been imagined; and that when they do occur, they are more attributable to bad management and dressing, than to the actual necessities and nature of the case; that, as a general rule, they may always be prevented, if reasonable attention be paid to the preservation of a free and depending opening for the exit of matter throughout the progress of the case, such opening to be preserved in the dressing and splint, if any be used, as well as in the wound, which at this part should be left entirely uncovered; whilst he denies that the shock is greater than that attending an ordinary case of amputation. That with regard to Mr. Gay's objections, "that the operation for excision of joints is useless and unphilosophical, that primary disease is generally limited to one of the articular extremities of the joint, and that therefore it is a useless mutilation to remove more than that disease, and that, moreover, dissections show, that disease originating in bone, when arrived at that stage at which the operation of resection is generally employed, has extended itself far beneath the surface, and frequently along the shaft, for a third of its whole length, so that resection cannot accomplish its purpose, which must be manifestly the removal of all disease,"—Mr. Hancock observes, that the operation of resection is not an useless operation, is proved by the cases just related, as well as by those published from time to time by Messrs Syme, Fergusson, and others; and that it is not unphilosophical, is also amply proved by the fact of its being an operation of preservation, and a substitute for amputation; that a surgeon is not compelled to remove sound parts; neither is an operation less one of resection of a joint, because one of the articulating surfaces of such joint may be found healthy, and it may be deemed advisable to preserve it. As regards the condition of parts disclosed by dissection, Mr. Hancock would inquire whether such dissections were made upon parts removed by this operation? or were they made upon cases selected by the author, and decided upon by him as those upon which the operation would be performed? He was not aware that surgeons were in the habit of operating, with the almost certainty of leaving a large portion of disease behind them; and he would submit, that this very objection to the operation is a convincing proof of its efficacy; for if it has proved so successful when performed in so bungling a manner, and under such disadvantageous circumstances, how much more certain and beneficial will be its results when properly done, and performed at the right time; but he denied that the parts were usually in the condition asserted by Mr. Gay, when the operation for resection was performed. Cases did occasionally occur, in which the disease has progressed to such an extent, or even beyond; but these were exceptions, and he would refer to three of the preparations upon the table, which clearly demonstrate, that although the disease shall be sufficient to destroy the patient, the state of parts will admit of the entire removal of the morbid structures by the operation of resection, without any undue difficulty or mutilation of parts. If the question at issue rested simply between incising and excising joints, he would not for one instant deny the superiority of the former over the latter proceeding; but in those cases justifying excision of the joints, the selection is not between that operation and making free incisions into the joint, but between amputation of the limb and excision of the joint, or leaving the patient to die. Mr. Gay limits his method to those cases where the articulations are completely destroyed; and whilst Mr. Hancock admits that Mr. Gay has done good service in directing attention to this plan, he would observe, that when reduced to this condition, the parts can scarcely be regarded as joints, since they no longer possess the constituent structures of joints; whilst in a large proportion of cases requiring amputation or excision, the destruction of parts has not attained this state; that the necessity for such operations does not depend so much upon the extent of destruction or disorganization, as upon the degree of constitutional disturbance attending the progress of such disorganization; for in many instances the severity of the constitutional symptoms has necessitated amputation where the degree of disorganization has been comparatively slight, proving that the urgency of cases depends upon the powers of endurance in the patient, rather than upon the actual extent of disease or destruction of parts; so that whilst he readily admitted, that when completely disorganized—when the cartilages were entirely denuded and destroyed—incisions into the joint might prove of avail, he would urge, that in an equal, if not in a more numerous class of cases, the irritation produced by the progressing morbid changes is so excessive, that we cannot depend upon such simple means, but are forced to have recourse to the more decided plan of either amputation or excision.

Mr. Gay spoke at some length. He remarked that his paper had related to the incision and not to the excision of joints, which latter was touched upon rather incidentally than in detail; and if his views had been more fully given, they would probably have been somewhat modified. He still, however, supported the views which he had advanced in the paper, and regarded the operation of excision as unphilosophical, and one which rather improved the art than the science of surgery. He denied that the success of an operation was *per se* to be taken as evidence of its utility or its soundness, and said, if such were the case, amputation for aneurism might be said to be good, because it effectually removed the disease. Excision was a sort of amputation, and therefore a mutilation, and he objected to it as a substitute for an operation founded on the established principles of pathology. He contended, by reference to cases, that excision of the joint had been practised without reference to the origin of the disease or of the condition of the parts, and hence in some cases the opera-

tion had been unnecessarily performed. He objected also to excision, on the ground that no sufficient distinction was drawn between the primary and secondary diseases of joints, and he showed the difficulty that there would be in know ing when you had removed the diseased parts to a sufficient extent to determine that a cure would follow. He did not think that the result of excision had been so favourable as some had said, and believed that bad cases had been suppressed. He then referred to the statistics of Blackburn, Norman, Walton, Syme, and others, to show that, with the exception of cases of the elbow-joint, excision had not been even a moderately successful operation. He then proceeded to express his opinion that disease of the joints should be treated on the same principles as disease of the shaft of a bone—necrosis, for instance—and only such portion removed as was necessary to the recovery of the parts. He thought excision had been performed indiscriminately, and without sufficient reference to the structure in which the disease originated. He then made reference to his paper lately read before the Society, and published in the *Lancet*, and enforced his views with respect to incision, advocated in that essay.

Mr. Hird defended excision in proper cases as a safe and successful operation; it could not be otherwise than good, if after operation it was shown that the parts could not have been repaired, and that the patient was enabled to get his living in consequence of the removal of the disease. The cases laid before the Society that evening would show its value. It did not, he thought, matter in what structure the disease commenced in the joint, if the disease must be removed. With respect to operations on the hip being less successful than on the elbow, in the former, it must be recollected, we removed only the head of the bone, and not the entire joint. He thought sufficient time had not been given to show the value of Mr. Gay's plan of incision, "an intermediate proceeding between poultices, &c., and excision;" but the profession would give him credit if it was found by future experience to be successful. In Mr. Hancock's cases such a proceeding would have been useless. Of course, if a joint were unnecessarily removed, it would be unphilosophical.—*Lancet*.

TRANSACTIONS OF THE PHARMACEUTICAL SOCIETY.

SPECIMEN OF DECOMPOSED CHLOROFORM.

By Jonathan Pereira, M.D., F.R.S.

In July last I received from Mr. Grattan, apothecary, of Belfast, a specimen of chloroform, accompanied by a note, from which the following is an extract:—

Some weeks prior to October 25, 1851, I received from my friend Dr. McKillen a small bottle of chloroform which he had had of me two or three months previously, and which he stated was subject to very singular changes of colour, despite the stopper never having been removed. At the time he handed it to me the fluid exhibited a delicate pink tint, as though coloured with cochineal, and was put aside in a glass case in my shop, of which I kept the key myself. The case was exposed to the diffused light of a large shop window, but not to the direct rays of the sun. Conceiving that the chloroform had by some unobserved means or other become accidentally coloured, I took very little interest in the matter, and was not surprised to find it fade gradually, and in a short time become perfectly colourless—and I made a note to that effect upon the 25th October, concluding that there must have been some error of observation on the part of Dr. McKillen. On the 16th of November, however, it again began to change, and the enclosed notes were made from time to time, as I happened to have opportunity of noticing it. I tried it under different conditions of light and temperature, without their exerting apparent influence upon it, and being unable to form the slightest conjecture as to the cause or nature of the molecular disturbance which produces these chromatic changes, have taken the liberty of forwarding it to you, should you consider it worthy of attention.

The specimen of chloroform sent me by Mr. Grattan was, in July, quite colourless, and on the sides of the bottle a few minute crystals were observed. The stopper of the bottle was, however, so firmly fixed in, that I could not remove it, and I therefore placed the bottle on the mantel shelf in my library exposed to diffused light, for the purpose of observing the changes which its contents would undergo. In the course of a few weeks it began to acquire a pinkish or amethystine tint, as described by Mr. Grattan. This slightly augmented in intensity for a few days, and then became somewhat paler. But for several weeks, during which it remained in the same situation, it never became colourless, though the intensity of the colour was frequently changing. The colour of the liquid was precisely that of a weak solution of permanganate of potash. Some weeks ago I placed the bottle in a dark cupboard, and at the expiration of about three weeks found that the liquid had become quite colourless. As the stopper was still immoveable, I was obliged to cut off the neck of the bottle to get at the contents. I then found that the chloroform had undergone decomposition, and had acquired a powerful and irritating odour, somewhat allied to, but distinct from, that of hypochlorous acid. The vapour yielded white fumes when a rod moistened with solution of ammonia was brought in contact with it, blue litmus paper was reddened but not bleached by it. A few drops of the liquid were placed on a watch-glass and volatilised by a spirit-lamp; they left scarcely any appreciable residue. The crystals which lined the bottle were then examined. They were few in number, and not larger than pins' points. They were white, and when examined by the microscope, were found to be six-sided pyramids, like the crystals of sulphate of potash. Some of them were heated to dull redness in a test-tube without undergoing any appreciable change. When heated on the point of a moistened thread in the outer cone of the flame of a candle, they communicated a violet white tinge to the flame, characteristic of a potash salt. They readily dissolved in water, and the solution did not yield any precipitate on the addition of a solution of nitrate of baryta, showing that the salt was not a sulphate. The solution was boiled with nitric acid, and then treated with a solution of nitrate of baryta, but no precipitate was observed. Nitrate of silver produced in the aqueous solution of the crystals a white precipitate, soluble in ammonia, but insoluble in nitric acid. Whether these crystals were in any way connected with the change of colour which this sample of chloroform underwent, I am unable to determine; but I suspect not. I am anxious, however, to draw the attention of others to the subject in the hope that larger specimens of the salt may be obtained for examination. For at present the circumstances under which chloroform frequently undergoes decomposition are very obscure. Except in this instance, I have never met with, nor heard of, any sample of chloroform which underwent these remarkable changes of colour. The chloroform was transferred into another bottle, on the sides of which a few minute crystals are now formed. But since the removal of the stopper the pink colour has not reappeared. I suspect that the pink colour of the chloroform must have been due to the presence of manganese. If so, was this metal derived from the chloride of lime used in the manufacture of chloroform? Mr. Squire informs me that he has occasionally found the solution of chlorinated soda to become of a pinkish hue after being prepared a few days (not immediately), and that he has attributed it to some manganese carried over with the chlorine gas, as he does not remember to have observed this change when the gas has been passed through water before entering the solution of carbonate of soda. If this suspicion should prove well founded, it is obvious that the purity of the chloride of lime employed in the preparation of chloroform deserves the attention of the manufacturer.—P.S. Subsequently to the reading of this paper before the Pharmaceutical Society, I have received from Mr. William Huskisson, jun., a specimen of pink chloroform, which, he informs me, owes its remarkable colour to the presence of manganese, derived from peroxide of manganese employed in the purification of chloroform, as recommended by Dr. Gregory. Mr. W. Huskisson, jun., tells me, that he has observed in his

specimen neither the alterations of colour nor the crystals met with in the specimen sent me by Mr. Grattan.

The CHAIRMAN stated that he had never, in the various specimens of chloroform, of which his firm had always a large quantity in stock, observed the pink colour described by Dr. Pereira, nor had he ever seen any crystals deposited in the bottles, but he would have a more minute examination made with the view of ascertaining whether such existed. When the chloroform was first drawn over, and before it was purified, it frequently possessed more or less of a brown colour, but this was quite distinct from the character described in the paper which had just been read.

Mr. D. HANBURY observed, that the use of manganese had been suggested in the process for purifying chloroform, and its presence in this way might be accounted for.

Mr. BARNES thought it desirable that the decomposed chloroform should be examined for formic acid. Although constantly subject to decomposition, no satisfactory explanation of the nature of the change had yet been afforded.

ON THE PREPARATION OF SYRUP OF POPPIES.

By Mr. STOCKEN.

The author, in this communication, directed attention to a process for the preparation for the syrup of poppies, originally suggested by Mr. Thomas Southall, and published in the second volume of the *Pharmaceutical Journal*. He states:—The principal feature in the process consists in the use of cold water, instead of boiling, to extract the medicinal virtues of the poppies. Mr. Southall's process is conducted as follows:—The capsules, from which the seeds have been separated, are weighed, and then dried, by which they lose from ten to fifteen per cent. They are then bruised and passed through a sieve of three-eighths inch mesh. They are next macerated in a mashtub, several portions of cold water being added and stirred with them, to ensure the whole being uniformly moistened. About an hour afterwards, the infusion is drawn off from the bottom of the vessel, more water being poured on the surface; after which the infusion is allowed to run off during the day. The quantity of water used is about the same as that which is directed in the Pharmacopœia. The infusion is evaporated, as it is drawn off, to nearly the consistence requisite for making the syrup, and allowed to stand during the night. The clear portion is poured off the following morning, the remainder strained through a calico bag, and the sugar is dissolved in the clear liquor, with as much heat as is requisite for the purpose.

I have ventured to deviate from the instructions of Mr. Southall in some points.

1st. As regards the time specified for the poppies to macerate prior to the infusion being drawn off. He occupies a period of about thirteen hours—one hour for maceration, and twelve hours, or a day, for the required quantity to run off. I have extended the time occupied for maceration, from one to twelve hours, and another twelve hours for the infusion to run off.

2nd. As regards the quantity of water to be used, and the period at which the sugar is added to the concentrated infusion. I find that about two-thirds of the quantity of water ordered in the Pharmacopœia is sufficient to ensure the exhaustion of the poppies in operating as I have described. In converting the infusion into syrup, I add the sugar before the concentration has been completed, and then evaporate the solution until it indicates a density of 32 deg. by the saccharometer. The advantage of this mode of operating arises from the fact that a quantity of scum is thrown off during the evaporation with the sugar, which would not otherwise be separated, and the syrup is rendered brighter in consequence. Syrup of poppies thus prepared is not only better in appearance than that made according to the instructions of the Pharmacopœia, but it is not so liable to undergo fermentation.

In conclusion I may state, that the foregoing experiments have been made with Messrs. Tuffy and Smith's steam apparatus, which, for operations on the small scale, has been found to be economical, and to answer exceedingly well.

The CHAIRMAN was glad to find pharmaceutical subjects, such as this, of a practical nature, brought before the meeting, and had no doubt it would be the means of conveying information, not only to the members of the Society, but also to the authors of Pharmacopœias, which would tend to the improvement of our processes. With regard to the observations of Mr. Stocken, he confessed that he did not agree with him on all points. He thought the resulting syrup was better when the poppy capsules were boiled, and not previously bruised, than when they were treated as had been described, with cold water. The boiling water extracts more of the true characteristic flavour of the poppy, and if the syrup be made of sufficient density it will not undergo fermentation.

Mr. DEANE had, for the last twelve years, adopted a process for the preparation of syrup of poppies, almost identical with that described by Mr. Stocken, and had always obtained a good result. He found that cold water extracted the whole of the active matter of the poppy, and that the product was less liable to undergo fermentation than when the capsules were boiled. In his process he was accustomed to evaporate the infusion in a vacuum pan. He might further observe, that he had found the addition of a little spirit, as directed in the Pharmacopœia, promote the preservation of syrups.

The CHAIRMAN said his experience was not favourable to the use of spirit in the preparation of syrups. He thought they kept better without it.—*Phar. Jour.*

ORIGINAL COMMUNICATIONS.

CASE OF CANCER IN THE LIP.

By J. M. BARRY, L.R.C.S.I.

THOMAS BYRNE, aged 60, applied for advice for a tumour on the lower lip, projecting midway between the middle line and angle of the lip on the right side. The tumour was very hard, and admitted of being lifted up and isolated from the healthy structures surrounding it. It extended about half an inch superficially, but was not very deeply connected with the substance of the lip. He suffered frequently from pain, which he described as darting through the tumour. He was always a healthy man until this disease made its appearance, about two years ago. Previously to his noticing it, he suffered from excoriated lips, owing to a cold he was labouring under.

The disease appeared in the form of a pimple, about the size of a pin's head, so hard, he thought some foreign body must have lodged in the lip. He paid but little attention to it until about six months since, when he applied for advice to a medical gentleman in the country, who apparently destroyed the morbid growth by the free application of nitrate of silver. The disease after a short time reappeared, larger and more painful; increasing more rapidly in six months than it had in the year and half previously. Finding his health becoming indifferent, and his mind most anxious, he came to me for advice. I at once recommended its removal by excision, which he consented to, and I performed the operation in the following manner:—Perceiving, as I have already stated, that the disease did not extend very deeply—in fact not more than to half the thickness of the lip—I therefore removed the diseased part by a semilunar incision, extending in depth half way through the lip, and superficially rather more than half an inch in length. I now, however, in bringing the opposite sides in conjunction, previous to passing the pins, found the portion of the lip I had left anything but an advantage, as it bulged inwards, forming a receptacle for blood or matter that might be suffused, and preventing the sides of the wound from lying as neatly in apposition as I could wish, so as to render union by the first intention more probable. I, therefore, before going further, removed this objectionable portion, when, having brought

the sides of the wound together, passed the pins, and applied the twisted suture in the usual manner, I found every thing as neat and satisfactory as I could desire, and the case progressed most favourably. On the fourth morning I removed the pins, when union had completely taken place, and in a week the man had perfectly recovered, without the slightest mark or deformity. The only point in the above case which I conceive worthy of making public is, the fact of my having, in the first instance, left the deep portion of the lip that was healthy untouched, and finding, as I have related, the disadvantage thereof.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S.

Strangulation of Intestine.

John W——, aged 23, was admitted into John ward, October 1, 1851, under the care of Dr. Burrows. The patient was suffering intense pain in the abdomen when he entered the hospital, calling out with extreme agony, during the paroxysms of which the intestines were raised in knots beneath the abdominal walls. The pain seemed relieved by gentle friction on the surface of the abdomen, but much increased by pressure. The man's countenance is expressive of much suffering and exhaustion, his cheeks drawn in, his eyes sunken, lips pale, tartar on the teeth, &c. He vomits after everything he takes, the matter ejected being copious, yellowish-green, sour, and emitting a suspiciously fæcal odour. The skin is cold; pulse small, slow, and feeble; the tongue moist, covered with a brownish fur, a bluish margin being distinguishable on the gums. There has been obstinate constipation for the three last days.

The patient is by occupation a shoemaker, and generally enjoyed good health. Five years since he had fever, and leeches were at that time applied to the left side of the abdomen, the marks of which are still visible. About a fortnight before admission, he suffered from pain in the abdomen, and diarrhœa; the symptoms were, however, not severe; he took some brandy, and was well in two days, remaining so until four days before admission, when the pain returned. Three days previous to his reception into the hospital, the patient ate a great deal of suet pudding, and took much cold water before and after the meal. On the morning of the next day, he was awoke by severe pain in the abdomen, and diarrhœa, which lasted about four hours, and has not had any evacuation since that time.

Mr. Wood, the resident medical officer, ordered a warm bath, sinapisms to the abdomen, and an injection of compound senna infusion. The enema having had no effect, a second was administered in a few hours, and brought away a little fæcal matter. The patient took, at the same time, tartrate of soda, with small doses of Battley's solution.

In the afternoon of the next day, the patient was seen by Dr. Baly. No relief had followed from the medicine; the suffering was very great, the man frequently jumping out of bed with pain, and his knees being drawn up to the abdomen. He was now given three grains of calomel, with fifteen of jalap, which doses were to be repeated six hours afterwards, if found necessary. He likewise took draughts of tartrate of potash, with sulphate of magnesia and laudanum, every fourth hour; and was allowed two ounces of brandy.

Dr. Burrows saw the patient in the evening. The pain was then extreme, causing him to be constantly calling out, throwing himself about, and begging for something to give him relief. Now and then cramp in the leg came on, and the same kind of fluid as above described was frequently ejected from the stomach. The appearance of the abdomen was irregular and knotted, and there was dulness on percussion over its lower portion. About one hour previously, the patient had taken thirty drops of Battley's solution, and had been given a soap injection, which had brought away some fæcal-looking fluid

Dr. Burrows ordered inhalations of chloroform; two grains of opium to be given immediately; and one grain every other hour, if found necessary; fomentations to the abdomen, and two ounces of brandy. The patient after having taken the opium, was kept under the influence of chloroform for about a quarter of an hour, when he awoke in considerable pain, but subsequently fell asleep again till three in the morning, when he took another pill, and slept till five At eight a.m., he took the sixth pill, since which they were discontinued. During the morning, the patient was almost free from pain; the countenance was expressive of exhaustion, but had now become calm. He now took a considerable quantity of gruel without sickness; the pulse was 96, and very soft; the tongue dry, the dorsum covered with a grayish white fur; the urine scanty, and passed with difficulty; and the bowels still confined. But vomiting came on again in the course of the morning, the matter ejected looking bilious, and emitting a fæcal odour; the abdomen was very tense, and dull on percussion in the hypogastric and inguinal regions; and the patient conscious of vomiting fæcal matter. One grain of opium was now ordered to be taken every hour, if the pain were very severe; and a warm bath, in which an enema was to be given. It was found, on the third day, that the injection given in the bath had come away slightly coloured, but unaccompanied by fæcal matter. There had been but little sleep in the night, the pain not being, however, of the former violent character. A small quantity of urine was withdrawn by the catheter. The pain was decidedly less when the patient lay still, and the vomiting was now replaced by occasional slight retching. The symptoms were about the same as on the previous day. The acute pain was, however, now referred to the left side and a little below the umbilicus, and a fæcal taste in the mouth complained of.

Mr. Wood passed the elastic tube into the rectum towards the evening of this day, but could not get it higher than four or five inches, probably owing to obstacles offered by folds of mucous membrane, as there was no difficulty in throwing up an injection; but the latter did not bring away any fæcal fluid. The night was pretty good, though the patient was frequently disturbed by pain.

In the course of the fourth day he became very weak, the abdomen bore pressure better than before, and the superficial veins became now very prominent. He was ordered a common enema, and opium pills every sixth hour, with alkaline draught every fourth hour. The injection came away without any fæcal matter, though it was reported by the sister to have been very slightly coloured and very offensive.

The patient passed the night in great pain, the exhaustion increased, nothing was evacuated from his bowels, and he vomited occasionally, the matters ejected being of light colour, and very sour. During the morning of the fifth day, the symptoms of collapse increased still more, and the patient sank at two in the afternoon.

The post-mortem examination was conducted by Dr. Kirkes, demonstrator of morbid anatomy to the hospital. On opening the abdomen, a band was seen passing between the internal surface of the abdominal walls and the intestine, at a point two or three inches below the umbilicus. Mr. Paget and Dr. Kirkes, after examining this band, found that it consisted of the obliterated omphalo-mesenteric duct. The latter ended in a diverticulum about two inches long, which joined the small intestine one foot and a half above the ileo-cæcal valve. The duct was impervious, and the diverticulum not quite so wide as the intestine. This diverticulum was twisted around the two ends of a large knuckle of intestine about half a foot long, and compressed these ends together. Between the constriction and the junction of the ilium with the cæcum were two inches of intestine, pale in colour, and quite empty. Above the constriction the intestine was distended by liquid fæcal matter. The portion of intestine constricted was of a very dark colour, and slightly distended by fluid stained with blood; the surface was smooth, but the coats thickened, and the mesenteric glands much enlarged.—*Lancet.*

PRACTICAL RULES ON THE SUPPRESSION OF ARTERIAL HÆMORRHAGE.

By Professor Syme.

In the first place, you should hold it established, that it is always desirable, if possible, to arrest bleeding from arteries by means applied at the seat of injury. Secondly, you may be assured that bleeding at and below the wrist, and at and below the ankle, is always under the control of pressure, provided it be properly employed,—that is, not superficially, but from lint, or some other suitable substance being introduced into the wound, and made to press directly upon the orifice of the vessel. Thirdly, in wounds of all arteries, accessible between the limits just mentioned and the heart, the vessel should be exposed at the seat of injury, and tied on both sides of the wound it has sustained. This principle has been so loudly maintained by Mr. Guthrie, that I believe some people have given him the credit of its origin; but it has been long established as a sound principle of practice by surgeons of the highest eminence both at home and abroad, and more especially by Mr. John Bell, of Edinburgh, in whose Principles of Surgery you will find many graphic and impressive lessons of the effects resulting from attention to it, and also from its regard.

One evening I received a message from the Northern Railway, that there was a steamboat waiting at Granton to carry me across the Firth to Burntisland, where a special train would be ready to proceed onwards, but whither, or for what purpose, there was no information. Having travelled a considerable distance, I met several practitioners, of great experience and intelligence, who were suffering much anxiety in regard to a youth, in whose forearm an incision for an abscess had bled profusely. As it was quite away from the radial artery, the ulnar was concluded to be the source of hæmorrhage, and had been sought for by dissection upwards towards the elbow, along the course of the muscles, between which it is wont to run, but without success; and, as the patient seemed little able to bear any further loss of blood, it was deemed desirable to have a consultation as to the most efficient measure of relief, even though it might involve ligature of the humeral artery, or removal of the limb. Acting upon the principle above mentioned, I scratched away the clot at the bleeding point, from which a copious stream instantly issued, but arresting this with my thumb, pressure being at the same time made upon the humeral, I dissected a little through the adjacent texture, and brought into view a large artery, under which a double ligature was passed, and tied on both sides of an aperture distinctly visible in its coats. In less time than I have taken to describe the process, the patient was thus transferred from a state of extreme danger to one of perfect safety. The artery was obviously the ulnar, which had come off higher than usual from the humeral, and pursued an irregular course externally to the fascia of the forearm, thus explaining how it had been wounded by the superficial incision, and how it had escaped the deep dissection.

The fourth rule I have to offer is, that when an aneurism forms after the wound of an artery, the same means should be employed as in the first instance, unless the vessel concerned be of a large size, and admits of having a ligature applied to it, without the intervention of any large branch between the seat of obstruction and the wound. The formerly not uncommon case of aneurism at the bend of the arm, as a consequence of the humeral artery being wounded in venesection, affords a good illustration of the advantage resulting from attention to this rule, since relief was thus afforded much more easily, safely, and securely, than by ligature of the humeral farther up the arm.

To illustrate the exception mentioned, I may relate the case of a young man, who, in one of the most remote of the Orkney Islands, accidentally thrust the blade of a knife into the middle of his thigh, so as to wound the femoral artery. The blood gushed forth with great violence, but was restrained by a compress, formed of eight half-crowns, wrapped in a piece of cloth. The wound healed, and an aneurism soon afterwards appearing, he was sent here to my care. Respect for the general principle, and suspicion, from the purring sound, that there was a communication between the artery and vein, suggested considerations which were opposed to ligature of the femoral, but I nevertheless preferred this operation, as the ligature could be applied without the intervention of any considerable branch; and I accordingly performed it, with the happiest result.

The following case will show the danger of not strictly limiting exceptions to the rule within the limits which have been mentioned. A middle-aged woman, in a country town, while walking up a steep and slippery ascent, and carrying a knife, with which she had just killed a pig, fell, and thrust the sharp point of the blade completely through her leg, a little below the knee, entering between the tibia and fibula, and issuing at the lower part of the popliteal space. Blood gushed from both openings, but when she was laid in bed ceased, and did not return. At the end of a fortnight, the wounds having healed, she attempted to walk, and found that a swelling had taken place at the seat of injury, on account of which, by the advice of her medical attendant, she came here to be under my care. On examination, I found a large pulsating tumour in the fore part of the leg, immediately below the knee, and another of equal size in the popliteal cavity. Feeling unable to determine whether the anterior or posterior tibial, or the popliteal artery itself, was the vessel wounded, and, on the whole, being inclined to think that the one last mentioned was most probably concerned, in which case ligature of the femoral would be the proper course, I adopted this measure. No bad consequence followed the operation, the tumours ceased to pulsate, and favourable expectations were entertained of the result for two or three weeks, when the anterior wound below the knee opened and bled profusely. I dilated it freely, evacuated the cavity of its fluid and coagulated contents, and applied firm pressure between the tibia and fibula, whence the blood was found to issue. Mortification followed, and I performed amputation, without saving the patient's life. There can be no doubt that, in this case, if the true state of matters could have been ascertained, and a ligature applied to the anterior tibial, which was divided just before it passed through the interosseous ligament, both the limb and life of the patient would have been preserved.—*Monthly Journal of Medical Science.*

TUMOUR COMPRESSING THE RIGHT SIDE OF THE MEDULLA OBLONGATA AND THE NERVES PROCEEDING FROM IT.

The following case was related to the Society of Biology in Paris by M. Charcot:—The patient, a woman aged 48, was admitted into the Charity Hospital on Feb. 28. She had been ill three months; and at first was under the care of M. Gubler. He was called to her a fortnight after the appearance of violent pain in the occipito-temporal region. The neck was slightly tender on pressure; the organs of sense were very susceptible; and every movement of the body brought on attempts to vomit, sometimes followed by a discharge. The pupil was much contracted; and there was obstinate constipation; but no distension or tenderness of the abdomen; the tongue was rather white, but moist; the pulse was not frequent; the skin was not hot; there was no pain in the trunk or limbs, nor paralysis, vertigo, or convulsions. M. Gubler diagnosed a superficial circumscribed softening of the gray matter, or rather an intracranial tumour. He applied leeches behind each ear, gave a calomel purgative, and ordered chloroform to be applied locally to calm the cephalalgia. Considerable relief ensued: but the patient was removed by her son two days after. She soon began to manifest great hebetude, and weakness in all her limbs, without pain; and at last her speech became very remarkably impaired. The cephalalgia soon became as severe as before. A seton was applied to the neck, and blisters to the thighs, but without effect; and she was admitted into hospital.

On admission, she answered questions pretty readily, but soon showed how much her intellect was weakened and perverted. She complained of very severe pains in the cerebellar region: the head was constantly turned towards the right shoulder, but there was no rigidity or contraction of the muscles of the neck. All her limbs were relaxed; but she moved her legs and arms without much difficulty, when desired to do so. When pinched, she felt it readily. There was no strabismus, ptosis, or deafness. The pupils were equally dilated. She had never vertigo, muscæ volitantes, or noises in the ears. There were no signs of paralysis of the facial nerve. She protruded her tongue readily; but the point was immediately carried to the right. She could, however, easily turn it in her mouth, and could turn the point to the left when desired to do so. The movements of deglutition were perfect. The vomiting and constipation continued as long as the patient was in the hospital. A kind of coma supervened, and the patient died on March 9th: she never had convulsions.

From the symptoms it seemed probable that there was a tumour compressing the ninth nerve; but there were no symptoms of syphilis, tubercles, or cancer. On post-mortem examination, a tumour, of the size and shape of a large pigeon's egg, was found on the front of the right lobe of the cerebellum, where it had formed a hollow. It also compressed the right peduncle of the brain, and pushed the medulla oblongata towards the left side. It had flattened the auditory, facial, pneumogastric, glosso-pharyngeal, and especially the hypoglossal nerves on the right side. The fifth pair was also much flattened. The third and sixth nerves were untouched. The tumour was very feebly adherent, and was easily removed by tearing some very loose cellular tissue. It was hard and dry, and grated under the scalpel: it was somewhat mammillated. Examined with the microscope, it presented fibro-plastic tissue, with a predominance of the fibrous tissue.—*Lond. Journ. of Med.*

CASE OF MOLLITIES OSSIUM.

By Mr. Mason of Holloway.

The subject was a well-formed female, æt. 30, of extremely healthy appearance, having light hair and blue eyes; her features were good, and the expression of her countenance exceedingly intelligent. She is stated to have enjoyed good health up to the age of 21, at which time she experienced a fall down a dozen stone steps, hurting the lower part of her back rather severely. At 24, she began to grow weak, and felt very much exhausted after ordinary fatigue of any kind. A short time after this she was treated for rheumatism, and bled, leeched, &c.; but continuing to get worse, she was advised to go to Bath, and avail herself of the benefit of the waters. She sojourned here for five months, without improvement, her strength becoming more impaired daily. This impairment of her strength, however general, was felt most in the right lower extremity, and was accompanied by a pain proceeding downwards from the spine towards the limb; and it was at this period that the first palpable indication of the disease under consideration presented itself, in the limb becoming bent. Soon afterwards, she began to suffer from violent spasms in the same limb, which became now quite incapacitated from its office, either as a member of progression, or support for the weight of her body. She was now compelled, therefore, to lie in bed, taking nourishing diet, and the vinum ferri as medicine.

The next important circumstance that happened in regard to the disease, was in the metacarpal bones of both hands becoming bent, and caused by the force used in grasping the bed-posts while getting in and out of bed. During this period her health generally was good. About this time she first came under observation, and the examination of her limbs gave the following appearances:—The metacarpal bones of either hand would seem to indicate as having been broken in their middle, or of there being a double row of knuckles; the left arm presented, just above the elbow, on the outer side, a hard lump, giving the idea of callus. This arm was quite useless, she being obliged to support and move it with her other one. On the radius of this same arm there existed another similar lump, as also on the radius of the opposite side. The right thigh presented a largish projection about its middle, or more intelligibly speaking, the limb appeared bent. Although both lower extremities were equally weak, there existed no such deformity in the left. There was slight lateral curvature of the spine, The treatment pursued consisted in nourishing diet, in the shape of meat and porter, with occasionally fish, and rest in bed, together with the administration of the cod liver oil, in doses of half an ounce three times a day; and this mode appeared to have a most beneficial effect, for at the expiration of several months, not only was the general health improved, but also the condition of her limbs. The metacarpal bones of either hand projected much less, and were firmer to the feel. The swellings on either arm were much reduced in size, and the use of the left arm was gained to a great extent.

This case presents, in its outline, the same train of symptoms and phenomena as recorded by those authors who have written on this disease,—the general debility and muscular pains, and phosphatic deposits in the urine, preceding, in this case, as in all those on record, the softening of the bones. There are a great many cases of this peculiar disease related; and what is very remarkable, the subjects of it have been almost without exception females, and in some instances of a very advanced age. Mr. Curling mentions an instance, where the patient had attained the age of 71; and Otto, the celebrated pathologist of Breslau, notices a preparation in the anatomical museum at Bonn, the subject of which was nearly 80. The disease does not appear to be confined to the human species, for it has been observed in quadrupeds, as the lion, ox, &c.; and Mr. Solly mentions as having heard of its occurrence in dogs; and in all these instances, it has precisely simulated, in morbid respects, the softening characteristic of the complaint in man, the bones after death, as in the case of Madame Supiot (related in Cooper's Practical Surgery), having been easily divided by a common scalpel. The analyzation of the bones, in this disease, has proved the great disproportion of the calcareous and organic substances, the phosphatic elements not being more than one-fifth or one-eighth of the total weight of the bone; as also the almost constant presence of a peculiar red grumous matter, seeming to usurp the place of the phosphate of lime, which is considered by Mr. Solly as an adventitious morbid product, and not, as some have supposed, simply the fatty matter of the bone, altered by the effusion of blood into it.—*Lancet.*

CORRESPONDENCE.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I need not assure you that nothing but a painful sense of duty, and a feeling of what I owe to myself and friends, could lead me to ask a place in your columns for the following statement of facts, which I have given, nearly in the order of time, as they have occurred.

As a medical man I am exposed to the shafts of calumny, and could, like others, bear up under the attacks of envy or ill-will, but as my calumniators seem resolved to carry on their secret arts against me for the purpose of shaking public confidence in my professional abilities, I am compelled to have recourse to an appeal to public opinion as the best means of self-protection at present in my power. Could I have traced the slander up to its real author I might have easily dealt with him in another way; for the present, therefore, I must be content to publish the facts of the case, and leave my calumniators to answer for themselves at the bar of public opinion.

In the month of October, 1850, I was in attendance on the late Mr. Joshua Wauhope of Drumcarrow, during his last severe illness, which terminated fatally in less than forty-eight hours; finding his case extremely serious I suggested to his afflicted family the propriety of having a second advice. Dr. Roe of Cavan was immediately sent for; but as the distance was great and time precious, Dr. Moore of this place was, in the meantime, at the request of the patient, written for by me, and desired to bring with him some leeches and other requisites which I considered might be necessary.

On the arrival of Dr. Roe (nine hours after that of Dr. Moore), and when met in consultation both medical gentlemen fully concurred with me as to the propriety and necessity of the previous treatment.

Shortly after the death of Mr. Wauhope it came to my knowledge that it was currently reported that I had maltreated him; when, in vindication of my character, I wrote to Dr. Roe for an expression of his opinion, which he gave me in the following letter:—

"Cavan, 3rd January, 1851.

"My Dear Sir,—I regret it was not in my power to reply to your letter yesterday, the purport of which I must say greatly surprises me, as I never for a moment thought there was the least supposition of any *misunderstanding* or of *maltreatment* on your part of the late Mr. Wauhope's case; and I can also say that I have seldom met in any case more general uniformity of coincidence of opinion than there appeared to be on it, as well as a feeling that every thing had been done which art or science could suggest or advise for the relief or recovery of our very interesting patient, the terrible rapidity of whose fatal disease bade

defiance to any and all remedies; and the melancholy result appeared to be too plainly seen and felt, almost at the very outset, by the poor sufferer himself. I do fully feel with you that 'the person or persons who can feel a pleasure in vilifying or slandering their neighbour's character are truly to be pitied; but it is a sad reflection that there are too many in the world who really do so; but you may console yourself in the thought that you are not a solitary example of such base practices, and be assured such slander will ultimately recoil, and perhaps deeply wound its author.—Yours most truly, "GEORGE ROE.

"To Dr. Taylor."

On receipt of the above letter I called on the nearest relatives of the deceased and placed it in their hands, and was assured by each of them that such report had not reached their ears, nor would they give credit to it.

Feeling anxious to trace the author of the calumny, and finding it gaining ground principally in the *parish of Killenkere*, I was led on the 21st of July last to inquire of some of my patients in that neighbourhood if they had heard of it, when I was informed of the conversation quoted in my first note to Miss Winder, which had occurred about the month of January last, and which was corroborated by an equally respectable parishioner, who believed it to be true until convinced by reading the foregoing letter of Dr. Roe.

The absence of a particular friend, whom I was most anxious to consult, led me to postpone writing to Miss Winder until 6th September, when I addressed the following note:—

"Bailieborough, 6th Sept., 1851.

"MADAM,—I regret that I am obliged to address you on a subject which has been and is painful to me, and which ultimately must be so to you.

"Having been in conversation with a respectable parishioner of your father's, I learned that about the latter end of January last a conversation had occurred between the individual alluded to and you, in the course of which you made use of statements to the following effect—viz., that Dr. Taylor, being in attendance on the late Mr. J. Wauhope, had maltreated him by taking away blood generally when he should have used leeches. Dr. Moore being sent for brought leeches in his pocket, which Dr. Taylor refused to have applied, and at the same time said that Dr. Roe should be sent for; who, on his arrival, asked Dr. Moore if leeches or bleeding had been used; his reply was that leeches had not, but bleeding had, at which Dr. Roe shook his head and said it was all over.

"I now, Madam, request that you will, at your earliest convenience, allow me to have from your pen the *name* of the *author* of so minute a detail of circumstances.—With much respect, I am your obedient servant,

"JAMES TAYLOR.

"To Miss Winder, Killenkere Glebe, Virginia."

Miss Winder declining to answer my note, I received the following from her father:—

"September 8, 1851.

"DEAR SIR,—In answer to your note, my daughter requests of me to state that she has no recollection of having had a conversation such as you allude to.—I am, sir, yours faithfully, "H. M. WINDER."

Feeling dissatisfied at not receiving an answer from Miss Winder, I again addressed her in the same respectful manner, giving her the name of my informant, and the place where the conversation occurred, to which I received no answer, but a visit from Mr. Winder on the following Monday, when he distinctly told me that Miss Winder would not answer my letters, not having any recollection of the circumstance; but when pressed by me, his reply was that "it was the common report of the country, and that he had heard it." This assertion appeared to me rather strange, he having previously pledged his word and honour that he had never heard it. In order to shake my confidence in my informant's statements, he proposed to tell me a circumstance that would lessen that individual in my estimation, provided I would promise to keep it a secret, the idea of which I spurned at.

I can trace the work of malevolence from stage to stage; commencing with my treatment of my esteemed friend, the late Mr. J. Wauhope, who was endeared to me by a friendly intercourse of many years, and whom, after all, *the secret assassin of my character* blames me for hurrying off the stage in his last illness. After these outrages committed on my feelings and character, I am still exposed to the tale of slander; and I find that in a respectable circle my secret enemy has been making false statements, which I believe are calculated not merely to destroy my personal reputation, but my professional usefulness. It is painful for me to find that there is a disposition to screen my calumniator, and a strange unwillingness to aid me in punishing or even tracing out my slanderer. This whispering away of my character behind backs has led me to take this means to vindicate myself, and if in so doing I have been obliged to mention the name of one who was my patient and friend, I trust his friends will believe me when I say, that his memory is as dear to me as ever it was, and nothing but the necessity of the case would have induced me to enter on this course of self-defence, in following out which I am compelled to state facts as they have occurred.

The public have now before them the facts of only one of several attacks of envy and malevolence against me. The *Anglo-Celt* of the 12th of June, and the MEDICAL PRESS of 9th July last, contain the facts of another abortive attempt to injure my professional character; nor are the circumstances of the false and injurious representations made against me to the board of guardians, nor the exposure of my calumniator in the presence of same board, yet forgotten. My letter on that subject, published in the *Anglo-Celt* of the 24th of October, 1850, yet remains unanswered by Dr. Moore; whether want of time or want of courage has been the cause, let those who know best say. Thus I have felt it to be an imperative duty to place the conduct of my calumniators before the public in its true light, that they may be rendered powerless for future evil, and that others may be deterred from following their example. I am not conscious of having ever given any of my medical friends grounds of offence, and if my peace of mind and happiness have been of late wantonly assailed and trifled with, I hope this exposure will end the quarrel, and teach my very enemy to feel the meaning of the motto—"Nemo me impune lacessit."—I am, sir, your obedient servant, JAMES TAYLOR.

Bailieborough, Nov. 11, 1851.

We reluctantly devote so much of our space to the above, because we fear that the matter may not be of general interest to our subscribers, and because we are satisfied that Dr. TAYLOR required no such aid to relieve him from any such imputations as those he complains of. The affair, however, teaches a lesson. It reminds the practitioner of what he has to encounter and prepares him for it. Every one is liable to such attacks, and Dr. TAYLOR takes this too much to heart. An old practitioner we knew once comforted his son, a young practitioner, making similar complaint, by reminding him that if he was now condemned for doing wrong when he did what was right, he was often praised for doing right when he was wrong.

PRESENT DIFFICULTIES OF DISPENSARY SURGEONS.

THE following remonstrance is a most reasonable one. The homely saying "live horse till you get grass," seems applicable to our brethren, and the sooner it is otherwise the better. No time should now be lost in putting the machinery of the act into practical operation for the sake of both surgeons and patients:—

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In your comments on the dispensaries act, I do not find that you have alluded to the great hardship several of the medical officers of dispensaries labour under since the new act became law. Those dispensaries which were presented for at the spring assizes generally ended their year in October or November, and from the falling off in subscriptions for some years back, they seldom had any funds at the end of the year. From the great delay in the appointment of the medical commissioner and inspectors, several medical attendants of dispensaries have been for the last three months without any remuneration for their arduous services. Should the commissioners not be empowered to allow any remuneration in such cases, I would suggest that an addition to the salary be made for the first year, as some compensation to those men who daily risk their lives in the public service.—I remain, sir, your obedient servant,

JAMES P. SHEEHAN, M.D.

Buttevant, January 22, 1852.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—I read with considerable surprise, in the leading article of your journal of the 21st inst., a paragraph which purports to be a report of certain proceedings of the Gort Board of Guardians with reference to the formation of dispensary districts and the salaries of the medical officers attached thereto, under the late Medical Charities' Act. I beg to state I have been most unnecessarily and unjustly referred to in that report. *It is not the fact* that I did not remonstrate against the reduction of my dispensary salary to £50 per annum. I have to inform you that on that occasion I handed in a written remonstrance, which was read by the clerk of the union to a very full board of guardians (*some* were absent, of course *unavoidably*), and that this document still remains in the hands of that officer.

With respect to the observation that my salary was reduced from £91 5*s.* to £50 per annum, solely on account of the other appointments held by me under the board at the time. This is a complete fallacy. I believe I am correct in stating that the *sole* cause of this reduction in my salary was to relieve the pressure of taxation; for previous to its occurrence, there was not a single officer connected with the union (with perhaps one solitary exception) whose salary the guardians did not reduce. And this feeling was not confined to the guardians of Gort union: it prevailed generally at the time, and was extensively carried out in most of the western and southern unions. I believe the guardians of Gort union are as ready as any other to acknowledge the just principle that each duty should be paid for in regard to itself, and that if a medical man should happen to be in possession of two or more situations, and was found to discharge his duties efficiently and satisfactorily in each, this circumstance should not take from or lessen the value of his services in each respectively.

With regard to the future dispensary arrangements, *which are still under consideration*, I consider it would be highly improper of me to interfere. It might, to be sure, suit the views and speculations of certain parties to force me into an unseemly contest with the board of guardians, or place me in a false position with my professional brethren; but I must claim the privilege in this instance of using my own discretion and of being permitted to pursue that course which I deem to be my duty. Indeed, I feel fully satisfied if this matter be left, as I think it ought, in the hands of the board of guardians and the poor-law commissioners, it will be equitably arranged, and finally prove alike satisfactory to the ratepayers, the sick poor, and the medical gentlemen employed. Hoping you will excuse this trespass on your space which I have been forced to commit, I have the honour to be, sir, your obedient servant, MARTIN D. NOLAN, M.D.

Gort, January 23, 1852.

We can assure Dr. NOLAN that in alluding to this matter, we had no idea that it would cause any personal annoyance to him or any one else. We are most anxious to steer clear of all local differences of opinion.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JANUARY 28, 1852.

THE RISING GENERATION.

WE cut the following paragraph, some time ago, from the columns of the *Times* newspaper, where it formed part of an article "On the state of the Ministry," thinking it a good text upon which to found a few observations "On the state of our Profession":—

"It so happens that at this moment it is a general complaint in the political world, as it is elsewhere, that there are no young men of talent coming out. The rising generation, we are assured by those who have the best opportunity of judging, and the best reasons to be impartial, are particularly dull. There appears to be a blight in the crop, and sagacious observers look forward with apprehension to the time when the state of the world, the protection of order, the sustentation of virtue, and the propagation of genius, will have to devolve on those who are now young."

Is this true? and if true, is the observation applicable to young surgeons? We dare not answer the question in the affirmative, and we are not quite prepared to answer it in the negative; but perhaps the parties referred to may answer it themselves. Doubtless many will say it is but too true ("the present company always excepted"), it cannot be denied that "no young men of talent are coming out;" that is obvious enough, for if there are, where are they? The "rising generation," all must admit, are "particularly dull;" there is no gainsaying it. With the exception of BROWN of our hospital, JONES of Do-the-boys college, or ROBINSON of the Greenhorn's Journal, we cannot find a young man of talent in the whole list. It is all a blank. In this we cannot agree, because we are of opinion that, as regards "talents," young men are now as young men have been before; and because we think that the "rising generation," although dull enough, are not "particularly dull:" when we look at some of the passing generation who have feathered their nests, we cannot perceive that the rising one loses by the contrast. No, it is not that the rising generation are destitute of talents, or that they are particularly dull, it is that they want what in slang parlance is called pluck—more politely, self-reliance; or perhaps that they want the self-respect which leads to independence of character. They cannot go without some one to lean upon, or to hold by the tail. This, however, they say is a national failing, and is not to be laid to the door of one class of Irishmen more than another; but constitutional or not, it will account for the "rising generation" not "coming out." In some cases it amounts to a delusion, the unlucky subject of which becomes the slave of any one who fosters it. He selects some heartless old fox for a patron, and in the vain hope of being promoted, devotes himself to his service, to the neglect of his own interests, until he finds, when too late, that he has been a tool, when he thought he was a companion; or astounded by the display of house and equipage exhibited by a quondam master, fondly imagines that one so favoured by fortune can help him to some of the good things in his gift, and is disposed of accordingly. He is honoured with an arm in the street, gets share of a family dinner with a poor relation or country customer, or is even entrusted with an occasional visit to a thank-ye job; but there the matter ends. Such young men never "come out." Paralyzed, subdued, and bewildered by apparent kindness, they lose all independence of character, and in the sequel all their prospects in life; content to become agents to obstruct the advancement of any who tread on the heels of their patron, or to carry into effect his intrigues for the subversion of institutions in which he has no interest. "Young men" of another temper start with an exaggerated estimate of their talents and acquirements, with brains intoxicated by those shallow draughts of which the poet speaks; and they, too, must have a patron, and they find him in a senior of their own stamp. The dreaming *exaltado*, inflated by the applause of the ignorant, or the approbation of confederates who inwardly despise him, wants a successor to replace a used-up herald of his astounding exploits, and finds one amongst these "young men" of precocious powers. Congenial parties meet and exchange good offices, but the junior pays the penalty; he "comes out," it is true, but it is as a bubble which bursts as it falls: reversing the law of nature, he returns from butterfly to grub, and rests contented with offals as a reward for his services. It is not, we repeat it, that the rising generation want talent, or that they are particularly dull; it is that they want

intrepidity and that self-confidence which is the first requisite to great undertakings; that they are timorous and quail before shadows when they should face real difficulties. They fear to "come out," and leave public duties to those that come after them, never recollecting that a coming generation follows on their heels, and will speedily be found occupying the positions which they refuse to fill. We have no patience when we see the youth of our profession, as we may call them, skulking and sneaking into holes and corners, nursing their discontent and brooding over their embarrassments, instead of joining in common efforts for the attainment of common objects. Still less have we when we see them absenting themselves from meetings of the College which owns them, or from the Surgical Society, which, if they be really Surgeons, they should support, and all to display their desire to pay court to pompous doctors, surgical dummies, and rampant apothecaries. Our provincial readers will perceive that we address ourselves more to metropolitan short-comings than to rural delinquencies; but there, too, there is much room for improvement. Our country brethren have been and are now subjected to deplorable difficulties, but that is the very reason why they should prepare to meet them. The necessity of self reliance is as great, if not greater, than in the city, and the sooner they begin to organize with a view to coöperation the better. Let them not for one moment suppose that reliance can be placed on aid from this part of the world; on the contrary, it is perhaps from hence they have to expect additional embarrassment. The falling off of country consultations is matter of conversation in certain quarters, and the necessity for a new race less capable of dispensing with them is openly spoken of. Before ten years pass the Surgeons of Ireland may be thrust from their positions by a class which must send their difficult cases to town.

ADVERTISEMENT EXTRAORDINARY.

Ready-money Practice or Down with the Dust.—Dr. Williams, the Resident Physician of the South-Eastern Lying-in Hospital, Cumberland-street, Merrion-square, begs to inform the inhabitants of Dublin, that he has commenced the following mode of practice, viz.:—2*s.* 6*d.*, 3*s.* 6*d.*, or 5*s.* per visit, depending upon the means, whim, or inclination of the patient. Lowest midwifery fee, £1. Dr. Williams is author of the following works: Calomel in Abdominal Inflammation; the Pulse, an Important Guide in the Treatment of Disease; a Few Remarks on the Diseases of Children.

Some may think that we are called on to comment on this; but tolerated, if not tacitly sanctioned, as such have long been by both branches of the profession in Dublin, we must be excused. The advertisement is copied from the *General Advertiser* where similar advertisements are of weekly occurrence, notwithstanding the boast of the proprietors that such are rejected. By another advertisement we are informed that the author of the above has resigned his office in this hospital. As there are many of the name of Williams on the list of the College of Surgeons, it is only right to say that this is not one of them.

Extraordinary Extraction of a Foreign Body.—Three years ago, Mr. Greensmith of Halifax, swallowed a large needle, the extraction of which baffled all medical skill. During the above period, the needle caused Mr. Greensmith not the slightest uneasiness, until one morning last week, when, feeling a pain at the top of the head, he put up his hand, and feeling something sharp protrude, he pulled it out, and to his astonishment found it was the needle he had swallowed three years previously.

HISTORY OF COURT FOOLS.

The "History of Court Fools, by H. F. Flögel, Professor in the Ritter Academie, at Liegnitz," is the subject of the following essay.

The history of fools and of buffoons can be traced back to the dark days of antiquity; princes and commoners, high and low, delighted in them; the part was played by pedantic men of talent, rather than by real madmen, and there were towns and whole districts which had the unenviable repute of being the natural soil of fools. Thus the town of Troyes enjoyed the peculiar privilege of providing court fools for the kings of France. In Troyes, is still preserved a letter from Charles V. of France, in which he announces the death of his fool, and requires the Burgomaster of Troyes to send him another, according to ancient custom. The German Emperor, Charles V., son of the imbecile Jane of Spain, said of the Germans, that they did not seem to be clever, and really were not so.

The Emperor Rudolf II. could not bear a jester in his presence; probably because he was much inclined to melancholy. Richardson brings the origin of fools from Eastern countries, on account of the particular esteem in which the deranged were there held. The sayings of fools were reverenced as inspirations, and it was from this cause that they were allowed the freedom of carrying their satires so far. Owing to this circumstance, cunning and designing persons took the opportunity of "playing the fool,"—they could speak out the truth without fear of punishment.

Those who translate the word "morio" by court fool, make a great mistake, for morio meant, by the Romans, a man who was deformed. The morio had a humped back, bandied legs, a great shapeless head, a long pendulous nose, or remarkable features; in a word, the morio (morris dancer) was a mis-shaped being; and probably, besides, either weak-minded or an absolute fool. The morio was so constituted, both bodily and mentally, as to excite laughter, and was on that account taken advantage of and misused as a fool. The tasteless pleasure taken by the degenerated Romans in such unfortunates went so far, that there was held in Rome an express market for fools—Forum Morionum—at which the dealers publicly exposed for sale the morios, whom they had gathered from all parts of the world, and obtained for them large prices. A thoroughly deformed morio often fetched a thousand florins. Martial, viii. 13; "Morio dictus erat; viginti millibus emi." Further, "Plutarchus de Curiositate." Pliny and Martial both say that the morions were stupid and imbecile. Plinius, lib. ix. ep. 17; Martial, xiv. 210; Martial, viii. 13; xii. 95.

Court fools are mentioned in the East as early as the eighth century. Such a being is found to have existed at the court of King Attila. At the court of the Khalifh Harun-al-Raschid there lived a man whom the Mahomedans used to regard as one inspired or insane. The Sultans of Turkey have, or used to have, such persons about their court, whereof there can be seen a full account in a work by Nicholas Höniger—"Die Hofhaltung der türkishen Kaiser," Bazel, 1596, tom. i., s. 39.

The jester (Lustigmacher) at the courts of the German princes does not seem at all times to have been able to bear with sufficient patience the tricks which were so often played upon him; probably because the difference between a madman and a mountebank was not sufficiently well understood. As the Duke Lewis of Bavaria, September 16, 1231, was taking a walk after dinner to Kehlheim, over the Danube bridge, he provoked his court fool, Stich or Stichius, to such a degree, that the man became mad, and murdered the duke with a bread-knife. The murderer was destroyed on the spot by the attendants. (Aventinus Annal. Bojor. lib. vii., c. 3, p. 634, Ex. Editione Gundlingii.) Some relate this murder in a different way; but Aventinus's view seems the simplest and the most probable. The Baron (Freiherr) Jacob Paul Von Gundling acted the part of fool at the court of King Frederick William I., the name Gundling being given to him from the unlimited inclination forward of the trunk, which gave a creeping aspect to his gait. Thus came his stiff comic look, which he himself produced, to render himself an object of mirth. He could never be satisfied in drinking wine, and his constant complaint was thirst. That Gundling was a clever scholar and contributed something to history is well known. A psychological delineation of this extraordinary man would be of interest both in theory and practice. Gundling died 1731; at the examination after death there was found a perforating ulcer of the stomach.

A certain Kornemann from Halberstadt appeared about

the time of Gundling; he called himself Cron-Kornemann, was completely deranged, but nevertheless enjoyed himself. Subsequently, being in want of money, he cut his throat, but the wound was not fatal; he recovered, and was put into confinement.

The last fool that we shall mention here was one at Schweidnitz. Boteslaus II., the Little, Duke of Schweidnitz, died 1368, and with him ended that line of the house, his son having been murdered by a fool. In an old manuscript we read that "Duke Boteslaus and his wife Agnes had a son, whom the fool, before the father's death, killed with a tile at the castle of Bolkenhayn, in consequence of the Prince having vexed him and excited his anger. The fool was beheaded. We see that in the thirteenth and fourteenth centuries the doctrine of irresponsibility of action was not in vogue; this was certainly an omission in the law. In the present day we are inclined to pronounce the malefactor "irresponsible" upon very insufficient grounds; not, forsooth, as a manifestation of Christian love, but that advocates may show their sharpness and learning, and that writers may glorify themselves in the journals. The false humanity of the present age may bring Corsican vengeance into the land. As regards France, where matters are usually driven into extravagance, it is remarked that court fools were formerly attached to the court as "fous en titre d'office."

In the *American Journal of Insanity*, there is related a case of "pyromania," which bears somewhat upon the preceding remarks. A youth, of fifteen, who had abstracted money from several letters, set fire to some sheds, having been instigated to the act by another. The reporter of this case makes the concluding remark, that most "pyromaniacs" observed by him had manifested other insane and dangerous tendencies; they had stolen or murdered; and he concludes that the passion to set fire to objects cannot be regarded as so distinct a form of insanity as to require a special name. If such a young rogue were to escape punishment on the grounds of insanity, and the decision were to be taken as a precedent, it would be wise for us in all consistency to shut up the courts of justice, and to employ the judges' salaries in enlarging lunatic asylums over the whole land.—*Winslow's Psychological Journal.*

ARSENIC EATERS.

A TRIAL for murder took place lately in Austria, in which the prisoner, Anna Alexander, was acquitted by the jury, who, in the questions put to the witnesses, in order to ascertain whether the murdered man, Lieutenant Mathew Wurzel, was a poison-eater or not, educed some curious evidence relating to this class of persons. As it is not generally known that eating poison is actually practised in more countries than one, the following account of the custom, given by a physician, Dr. T. Von Tschudi, will not be without interest. In some districts of Lower Austria and in Styria, especially in those mountainous parts bordering on Hungary, there prevails the habit of eating arsenic. The peasantry in particular are given to it. They obtain it under the name of *hedri* from the travelling hucksters and gatherers of herbs, who, on their side, get it from the glass-blowers, or purchase it from the cow-doctors, quacks, or mountebanks. The poison-eaters have a two-fold aim in their dangerous enjoyment: one to obtain a fresh, healthy appearance, and acquire a certain degree of *embonpoint*. The number of deaths in consequence of the immoderate enjoyment of arsenic, is not inconsiderable, especially among the young. Every priest who has the cure of souls in those districts where the abuse prevails could tell of such tragedies; and the inquiries made by Dr. Tschudi on the subject have opened out very singular details. The second object the poison-eaters have in view is to make them, as they repeat it, "better winded!"—that is, to make their respiration easier when ascending the mountains. Whenever they have far to go, and to mount a considerable height, they take a minute morsel of arsenic, and allow it gradually to dissolve. The effect is surprising; and they ascend with ease heights which otherwise they could climb only with effort. The dose of arsenic with which the poison-eaters begin, consists, according to the confession of some of them, of a piece the size of a lentil, which in weight would be rather less than half a grain. To this quantity, which they take fasting several mornings in the week, they confine themselves for a considerable time; and then gradually, and very carefully, increase the dose according to the effect produced. A strong, hale man, upwards of sixty, takes at present at a dose a piece of about the weight of four grains. For more than forty years he has practised this habit, which he inherited from his father, and which he in his turn will bequeath to his children. It is well to observe, that neither in these nor in other poison-eaters is there the least trace of an arsenic cachexy discernible; that the symptoms of a chronic arsenical poisoning never show themselves in individuals who adapt the dose to their constitution, even although that dose should be considerable. It is not less worthy of remark, however, that when, either from inability to obtain the acid, or from any other cause, the perilous indulgence is stopped, symptoms of illness are sure to appear, which have the closest resemblance to those produced by poisoning from arsenic. These symptoms consist principally in a feeling of general discomfort, attended by a perfect indifference to all surrounding persons and things, great personal anxiety, and various distressing sensations arising from the digestive organs, want of appetite, a constant feeling of the stomach being overloaded at early morning, an unusual degree of salivation, a burning from the pylorus to the throat, a cramp-like movement in the pharynx, pains in the stomach, and especially difficulty of breathing. For all these symptoms there is but one remedy—a return to the enjoyment of arsenic. According to inquiries made on the subject, it would seem that the habit of eating poison among the inhabitants of Lower Austria has not grown into a passion, as is the case with the opium-eaters in the East, the chewers of the betel-nut in India and Polynesia, and of the cocoa-tree among the natives of Peru. When once commenced, however, it becomes a necessity. In some districts sublimate of quicksilver is used in the same way. One case in particular is mentioned by Dr. Von Tschudi, a case authenticated by the English ambassador at Constantinople, of a great opium-eater at Brussa, who daily consumed the enormous quantity of forty grains of corrosive sublimate with his opium. In the mountainous parts of Peru the doctor met very frequently with eaters of corrosive sublimate: and in Bolivia the practice is still more frequent, where this poison is openly sold in the market to the Indians. In Vienna the use of arsenic is of every day occurrence among horse-dealers, and especially with the coachmen of the nobility. They either shake it in a pulverized state among the corn, or they tie a bit the size of a pea in a piece of linen, which they fasten to the curb when the horse is harnessed, and the saliva of the animal soon dissolves it. The sleek, round, shining appearance of the carriage horses, and especially the much admired foaming at the mouth, is the result of this arsenic feeding. It is a common practice with the farm-servants in the mountainous parts, to strew a pinch of arsenic on the last feed of hay before going up a steep road. This is done for years without the least unfavourable result; but should the horse fall into the hands of another owner who withholds the arsenic, he loses flesh immediately, is no longer lively, and even with the best feeding there is no possibility of restoring him to his former sleek appearance. [The preceding extraordinary statement is abbreviated from a recent number of *Chambers's Edinburgh Journal*, in which it is given as authentic. The use of arsenic in improving the condition of horses is not unfrequent in this country, and its value in the cutaneous diseases of man is established. Such facts, in some degree, confirm these statements; but we entertain grave doubts that an agent of such uniform power as arsenic, could be commenced and habitually continued, in the large doses here mentioned, without producing effects the converse of those described.]—*Lancet.*

TREATMENT OF PROLAPSUS ANI.—The person on whom this operation had been performed had suffered severely from intermittent fever, and was much debilitated from its effects. While a convalescent, he was attacked with acute dysentery; and, during the efforts to relieve the bowels, a prolapse of the rectum occurred, when, experiencing insuperable difficulty in its reduction, he requested a non-professional friend who had called upon him, to be *so obliging as to cut it off*. This request was complied with, to the satisfaction and present relief of the sufferer. The bowel removed, when examined subsequently, was found to have been cut off by an irregular and oblique incision, so that it was of the extent of three inches on one side, and only an inch and a quarter on the other. On a close examination it was found that the specimen was composed of all the tissues of the gut. Urgent symptoms set in on the second day after the removal, when more of the rectum was extruded, and subsequently removed by operation, in consequence of the impossibility of treating it by any other method. The patient subsequently recovered.—*Med. Gaz.*

M. W. HANLON, M.B.

REGISTRATION OF BIRTHS IN FRANCE.—The Municipal Council of Lille have just decided that new-born children need not, as heretofore, be actually brought to the Town-hall to be registered, as such custom may, with weak children, and in the winter season, be extremely detrimental to health. It will now be sufficient for parents to make a declaration of birth, and medical practitioners will be appointed to verify the same at their residence.

Just published, 8vo, pp. 96, price 2s. 6*d*.,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

UNIVERSITY OF LONDON.

The following Works have been selected by the Examiners for the Examination in Logic and in Moral and Intellectual Philosophy, for the Degree of Doctor of Medicine, in the year 1852:—

Logic.—Bacon's Novum Organum, Part 1.

Philosophy of the Mind.—Cousin's Analysis of Locke's Essay (being the third volume of his Cours de Philosophie).

Moral Philosophy.—Butler's Analogy, Part 1. Stewart's Outlines of Moral Philosophy.

By order of the Senate,
R. W. ROTHMAN, Registrar.

Somerset House, December, 1851.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D.,
Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

LOUTH COUNTY INFIRMARY.

NOTICE is hereby given, that the Governors of the Louth County Infirmary will, on Wednesday, the 28th instant, receive Applications, and proceed to appoint a fit and proper person to fill the Office of Resident Apothecary to that Establishment, at a Salary of £40 per annum, with Apartments and Fuel.

Testimonials, &c., to be lodged with me, on or before Tuesday, the 27th instant.

No appointment will be made for a less period than Twelve Months.

Personal attendance of Candidates will be required.

Signed by Order,
ALEXANDER SHEKLETON, Secretary.

SURGICAL SOCIETY OF IRELAND.—JAN. 24.

Dr. JACOB in the chair.

IRREDUCIBLE HERNIA OF THE OMENTUM.

By Dr. BANON.

DR. BANON exhibited a preparation illustrative of the above disease. The subject of the case was a man, aged 84. He was admitted to the Jervis-street Hospital on the 28th of November last, labouring under the symptoms of strangulated hernia, together with those of acute bronchitis. He stated on admission, that he had suffered from hernia for nearly thirty years, which, until within the last few years, he had been always able completely to reduce with much ease. Two days before his admission, he was attacked with the symptoms of strangulation, and applied to several medical men without relief. He had also been subject to severe attacks of bronchitis, and was now suffering much dyspnœa. His general appearance was most unpromising; the pulse was rapid and flagging, so much so, that Dr. Banon at once came to the conclusion that should he fail in reducing the hernia by the taxis, an operation could not be had recourse to under the circumstances. After repeated efforts, a portion of the contents of the sac passed into the abdomen, but no impression could be made on the portion of the tumour which remained. A complete remission of the symptoms followed this partial reduction of the hernia; the vomiting and all the other distressing symptoms of strangulation immediately ceased; the bowels acted copiously; the dyspnœa and bronchitis, however, still continued, and increased in intensity; and on the day after his admission it was evident that the powers of life were fast failing. He continued in this state for some days, and at length sank under the bronchitic affection. From the period of the partial reduction, this patient had no return of any of the symptoms of strangulated hernia. It struck Dr. Banon that the tumour which remained was an irreducible epiplocele, in which view he was borne out by the post-mortem examination. On opening the abdomen, twelve hours after death, the peritoneum and intestines were found to be quite free from any inflammatory appearances; the hernia, which, as may be observed, is of very large size, is altogether composed of degenerated omentum; the neck of the sac will admit the little finger to pass into it by the side of the omentum, which no doubt allowed of the reduction of the intestinal portion of the hernia during life; no portion of intestine was now contained in the sac. Dr. Banon begged to draw the particular attention of the meeting to the extraordinary degeneration undergone by the omentum. An enormous deposition of fat had taken place between its layers; so much so, as to render the epiplocele totally irreducible—in fact, to convert it into a large fatty tumour. Dr. Banon thought the case worth bringing forward as affording a good specimen of fatty degeneration of the omentum.

ON THE ANATOMY OF THE GENERATIVE ORGANS OF THE HALICHÆRUS GRISEUS.

By Dr. CARTE.

An apology may seem necessary on my part for bringing before your notice a subject not strictly of a medical or surgical character, and I would hesitate ere doing so, but that you are aware this Society has always afforded free access to the collateral sciences, anatomy and physiology. I therefore trust I may be excused for occupying a short portion of your time this evening with a few observations upon the anatomy of the generative organs of the female seal.

I am induced to do so in consequence of a very favourable opportunity, which enabled me some time since to examine these organs in a fine specimen, the *Halichærus griseus*, and which on dissection I found to be in calf, and on the table you have one of the results of my investigations, that rare preparation, a fœtal seal in its membranes. It is, I believe, the first instance of the kind which has ever been so preserved in this city, and may therefore prove interesting to some of the members of the Society.

The natural history of the Phocidæ or seals, I shall not dwell upon, but merely state that Cuvier places them in the third order of the class mammalia, named by him *Carnassiers*, and which he has divided into three great sub-

orders:—1st. The Cheiroptera. Bats. 2nd. The Insectivora. Hedgehog, shrew, mole, &c. 3rd. The Carnivora. Bears, &c. This last family being further subdivided into three sub-families: 1st. The Plantigrade. 2nd. The Digitigrade. 3rd. The Amphibeæ.

Now, in this classification, the seals are placed at the head of the last sub-family, *the amphibeæ*, but of course inferior to the terrestrial carnivora.

These useful and interesting animals have often from time to time furnished materials for the study of the anatomist and physiologist; such, for instance, as the great venous sinuses, first described, I believe in this very room, by my talented predecessor, the late Dr. Houston.

The peculiar arrangement of the sclerotic coat of the eye, as recorded by Blumenbach, in the Greenland or harp variety, and upon which he based his theory to account for the adaptation of the eye, as an optical instrument, to different media and distances.

Also the circular disposition of the tapetum and spherical lens; the valve in the fauces; the great extent of the olfactory mucous membrane; the distribution and size of the nerves supplying the lips, &c.; but as these are all irrelevant to the immediate subject before us, I shall pass them over, and proceed to that which is the object of the present communication.

On looking at the external parts of generation, we find the orifice of the *urethro-sexual* canal very capacious, in close connexion, but anterior to the anus: one muscle encircling both outlets, and forming a common sphincter; deeper seated these canals are merely separated by some loose cellular membrane, fat, &c.

Immediately within the verge of the *urethro-sexual* canal, and on its anterior wall, the *clitoris* lies in a small semilunar depression, *the preputium*. This organ, like its analogue, the penis of the male, is capable of erection during sexual excitement. In shape it resembles a diminutive tongue; it is denticulated on its free edge (the glans), but in this instance is destitute of that bony support which exists in the penis of the male. This, then, is another exception to the rule—namely, that when the *intromittent* organ of the male is provided with a bony support, we also find one, or the rudiments of one, in the clitoris of the female. For instance, it exists in both sexes in the bear, the cat, the lion, racoon, marmot, and otter, &c.; yet though present in the penis of the dog and civet, it is not found in the female civet or bitch. In this particular, then, the seal resembles the dog, and another proof of this resemblance may be drawn from the fact that the penis of the seal (*P. vitulina*) is furnished with the *musculi compressones venæ dorsalis* like the dog (also first described by the late Dr. Houston); they are long and thick, and meet in a tendon over the dorsal vein, where that vessel runs under the arch of the pubes. (*Vide* Prep. R.C.S.I. Fb. 207.)

Proceeding from the clitoris a median raphe extends a short distance along the *urethro-sexual* canal, having two small eminences separated by a shallow groove or furrow. These eminences appear to be the rudiments of the *labia minores* or nymphæ. In other respects the mucous membrane of this canal is smooth except at its verge, where it is thrown into circular folds by the action of the sphincter muscle.

At its upper or distal extremity there is a well-defined circle of *fimbriated* mucous membrane which is particularly prominent on the anterior wall, where it forms a soft fleshy eminence, and which, to a superficial observer, might be mistaken for the os tincæ. On the right side of this protuberance the *urethra* opens by a slit-like orifice which leads to a pyriform bladder by a straight *urethra* about three inches and a half in length, and is situated in the median line of the anterior wall of the vagina.

From the apex of the bladder the urachus is continued towards the umbilicus, and its peritoneal reflections or false ligaments pass off on each side as far as the round ligaments of the uterus.

The mucous membrane of the *vagina proper*, though smooth on its surface, is nevertheless disposed in longitudinal rugæ. This part of the canal may be said to commence at the fleshy eminence just described, on which is situated the orifice of the urethra; and in the young or immature female, this circular constriction separates the *uro-sexual* canal from the true vagina, but which in the adult, after impregnation, is broken by numerous fissures into prominent folds, resembling the *corpora myrtiformes*, the remains of the hymen.

The distal end of the vagina proper is terminated by the *os uteri*, and its lips project considerably into this canal, the posterior being much the longest.

The body of the *uterus* extends for the distance of about three inches, and then divides into its two *cornua*, which pass off in the direction of each iliac region. But the cornua are united to each other in the median line for some distance before they open into the body of the uterus; and consequently appear *externally* to give a greater length to the uterus than really exists internally.

Each *cornu* is terminated by the ovary of its own side, and these bodies are each enclosed in a duplicature of the peritoneum, somewhat similar to the disposition of the same organs in some of the ruminantia, as, for instance, the *Camelus Bactrianus*. (*Vide* Prep. Fc. 403, Anat. Coll., R.C.S.I.)

These capsules strongly resemble the tunica vaginalis testis of the male. They are formed by reflections of the peritoneum, and contain within them glands analogous to testicles. At the same time, I need scarcely say, anatomically speaking, that ovaries differ in a very remarkable manner from testicles, and in fact from most other glands, in that they are quite separate from their efferent ducts; and this may be considered as one of the most striking differences in the anatomy of the generative organs of the two sexes in the higher classes of animals.

To account for this separation of a gland from its duct, some physiologists ascribe as the reason the *greater distance* which exists between the two branches of the spermatic vessels in the embryo of the female than in the male.

It is in such questions as the present, that comparative anatomy becomes useful; for if we trace the development of the genital organs in both sexes through the lower animals, we find much light upon this otherwise most difficult problem.

The testicles or ovaries originate from two long fusiform deciduous bodies, first described by Wolff, and hence called *Corpora Wolffiana*, or false kidneys of Rathke; these bodies in birds, reptiles, fishes, and in the embryonic stage of quadrupeds and man, lie along each side of the spine, extending nearly the whole length of the abdomen. In fact, the long parallel testicles and kidneys of osseous fishes retain this embryonic shape through life, much in the same form as when first they were developed from the inner sides of the corpora Wolffiana.

But in quadrupeds the testicles or ovaries very soon change their form, becoming shorter and rounder, and are detached in or about the period of the closing of the last branchial openings in the neck.

The penis and clitoris are developed about the same period as the testes and ovaries, but both these glands prior to the kidneys.

The later and more extended inquiries of Müller and Valentin go to prove that the *genital organs proper* in both sexes are developed in two distinct parts—viz., 1st, that for the secretion or elimination of the generative substance, the testicle or ovary; and 2ndly, the duct for the conveyance of this fluid to its destination, the vas deferens, in the male or oviduct of the female.

When, then, we consider that the testicle or ovary, as the case may be, is formed on the *inner* or *concave* side of the corpora Wolffiana, and the vas deferens or oviduct (each of which at first is quite an isolated tube) is developed along its outer or convex border, from whence it extends to the common cloaca or sinus of the uro-genital and digestive tube below, we can readily understand that the sexual distinction of the male is stamped by the development of another series of tubes, constituting the *epididymis* which serve to connect the *formative* to the

conducting parts; whereas, in the female, there is an arrest of development, no epididymis is formed, and consequently no junction takes place, and the tube of the oviduct remains separated from the ovary, with its open extremity, though in close proximity, still not united to the formative organ.

In both sexes the lower extremities of the conducting tubes terminate in a common cloaca; but afterwards, when these parts are separated into bladder and rectum in the male, or into bladder, vagina, and rectum, in the female, they make their appropriate connexions; in the male forming the *vasa deferentia*, and in the female the *Fallopian tube and uterus*.

Both cornua are laid open to expose their mucous surfaces; that on the right or impregnated side is of an ovoid form and considerable size; when compared with the left, its walls are thinned by distension, and its mucous surface has completely lost the longitudinal rugæ, so well marked in the left or unimpregnated one.

At the upper and posterior surface of each ovarian capsule, there is a large round opening, at the upper and ovarian surface of which the fimbriated extremities of each Fallopian tube commences; above and behind each ovary in close relation, but not joined to these organs, except during fecundation, when they grasp the ovaries and allow the passage of the ovum along to the uterus. To facilitate this operation, the orifice of each Fallopian tube is situated in the centre of the fimbriæ, their trumpet-shaped extremities rather suddenly contracting into very fine tubes, which run in a diagonal direction from the upper and outer border of each capsule to the lower and inner angle, and in their course each Fallopian tube lies between the layers of the peritoneal capsules, and in front of the ovaries, and terminate by a very small orifice near the apex of each cornua.

The *ovaries* are somewhat *reneform*, and about the size of small walnuts; a section of the impregnated one discloses a well-marked *corpus luteum*.

From the upper and posterior part of each capsule, a long flat band extends as far as the diaphragm, to which it is connected merely by the peritoneum. These bands consist of a peculiar semi-elastic tissue, intermingled with *non-striated* fibre, and differing in both these respects from voluntary muscular fibre. These bands are inserted into the ribs nearly at right angles to the fibres of the diaphragm.

I conceive the use of these bands is, in the first place, to give support to the uterus, for it appears as it were slung between them, like a hammock; and secondly, when we consider their relative position to the round ligaments, being external and opposed to them, we find that the whole uterus is placed in the centre of four forces; two acting from the ribs, and two from the pelvis. In this manner the organ is kept in a quiescent state, and as those bands have in their composition more or less of the elastic tissue, when the uterus ascends, this enables them to contract, and when it descends, to elongate. And all this is necessary, when we consider the peculiar habits of the seal, at one time in water, at another basking on some rock. In the former element its motions are easy, but on land it is ludicrously awkward; a kind of shambling gait. They throw themselves forward by saltations or leaps; and under such circumstances, if the uterus were only supported in the ordinary way, it would be liable to violent shocks, and of course the fœtus injured.

Dr. Jacob, in reference to Dr. Carte's communication, observed, that although the subject to which he had called the attention of the Society was not likely to elicit a lengthened discussion, it must nevertheless be regarded as one of considerable interest; and he was convinced that the present paper would prove valuable hereafter as a contribution towards a department of comparative anatomy in which a large amount of fresh information was required. If any gentleman in the room wished to make observations or inquiries calculated to afford or elicit information, upon a subject of so much interest, an excellent opportunity was then offered to him; for it often happened, when a matter of this kind was brought forward, that remarks of very great value were thrown out, or questions propounded, to which the author of the communication would be glad to reply, or upon which to impart information.

Dr. Carte said, that about twelve months ago (15th April, 1850), a paper was read before the Royal Society by Mr. Rainey, in which that gentleman stated that the round ligament of the uterus consisted of striated fibre; and cited as a particular example the round ligament of the uterus of the cow. Now, he (Dr. Carte) had carefully examined the round ligament of a cow, and he was not quite satisfied that it consisted of striated fibre. As far as he was able to judge, it was striated, but by no means the well-marked striation which was to be found in a voluntary muscle. Mr. Rainey had also assigned to the round ligament of the uterus a very different function from that usually attributed to it, and one which, if it really had an existence, should be borne in mind by every accoucheur—namely, that this ligament was of use at the time of impregnation, and not at the period when the contents of the uterus were discharged.

Dr. Jacob was of opinion that the observations which had led to the present inquiries respecting striated and non-striated muscular fibre, must be carefully repeated, and the investigation of the whole subject be followed up for some time longer, before they could feel satisfied with the results.

ABSCESSES CONSEQUENT UPON THE BITE OF A CAT.

Dr. Bagot read a short communication on the formation of a series of small abscesses on the hand and arm of a girl of five years old, consequent on the bite of a cat. The formation of the first abscess commenced on the third day after the infliction of the bite, and was followed by others at short intervals, on the forearm and arm; some inflammation having been also produced in a circumscribed spot over the shoulder-joint, and again in the neck; no pus, however, being formed in those latter situations. There were not any symptoms of inflammation of the absorbents, and Dr. Bagot believed that the abscesses (which he remarked were ushered in by rigors and accompanied by fever) were the result of the absorption of a poison with which the child had been inoculated when bitten by the cat. He concluded by observing, that in many parts of Ireland a popular opinion prevailed that the bite of this animal was likely to be followed by bad consequences.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

REMARKABLE CASE OF FOREIGN BODIES IN THE STOMACH AND DUODENUM, COMPLETE OBSTRUCTION OF THE BOWELS, AND MECHANICAL DISPLACEMENT OF ORGANS.

By John Marshall, Esq., of Wallingford.

A tradesman's wife, aged 41 at the time of her death, who had borne six children—the last in 1844—a tall, well-formed woman, had suffered from the following symptoms:—In December, 1842, fourteen days after the birth of her fifth child, she vomited a washhand-basinful of blood. For forty-eight hours subsequently she was unconscious, the pupils were dilated, and the pulse hardly to be felt. She recovered slowly, and her complexion always retained a sallow hue afterwards. The last labour, in 1844, was unattended by any similar or other ailment, and she recovered quickly. In the autumn of 1845, she suffered from pain at the epigastrium and in the left groin, accompanied with frequent vomiting. A hard tumour, size and shape of an ordinary placenta, was found in the left groin, moveable in a transverse direction when the patient turned from side to side. This had been felt by the patient for many months; when it moved, it caused nausea, but no pain, nor was it tender to the touch. She had pain between the shoulders, shooting into the left breast, and suffered much from flatulence. The catamenia had not appeared for three months, and she thought she was pregnant. The bowels were constipated, the vomiting continued, with occasional mixture of blood in the matters thrown up, she became much ema-

ciated, and so feeble that her death was expected. She recovered, however, after taking nothing but small quantities of brandy at short intervals for two days. She gradually regained strength, and looked almost as well as usual. During the five following years, she continued in tolerable health: the pain and occasional sickness, constipated state of bowels, and occasional œdema of face and ankles, were the principal indications of impaired health. The catamenia had never returned since 1845. In October, 1850, after a return of the old symptoms of incessant vomiting, &c., she sank after an illness of three weeks.

Post-mortem examination eighteen hours after death.—The stomach was found reaching, at its pyloric end, the arch of the pubes, its form resembling that of a champagne bottle; the duodenum lay partly under the sigmoid flexure of the colon; the pancreas was also drawn out of its natural position; the liver was large and pale, and the gall-bladder full of bile. Nothing remarkable was observed in the other organs of the abdomen and pelvis, except that the cæcum and colon were small, and had lost the character of small intestines. No ulceration was to be found throughout the whole length of the intestinal canal, nor any adhesion or other sign of peritoneal inflammation. The stomach contained in its lower half nine ounces of pins of a purple-black colour, not corroded, all bent or broken, many very pointed. The contents of the stomach were much thickened; the duodenum contained a mass of pins very tightly packed, of various shapes similar to those found in the stomach, and wholly obstructing the tube. Their weight was about a pound. The husband of the patient had never seen her put pins into her mouth, but her son said that he had observed his mother biting pins, and believed that she swallowed them; and stated, moreover, that he had occasionally taunted her with the fact when she corrected him. It appeared that her appetite was always capricious, occasionally very keen; and her sister informed the author that when a child she was in the habit of eating starch and slate-pencil, and that she had seen her biting pins. At seventeen years of age, she had vomited blood, and was ill for some time afterwards.

Mr. Pollock had related a case to the members of the Pathological Society, which he might now briefly allude to, as many of the fellows might not have heard of it. It was a case of a girl, aged 18, who died at one of the lodges in the park, and who had been under the care of Dr. Blakely Brown, and he (Mr. Pollock) had examined the body. For some months she had been suffering from a slightly moveable tumour in the epigastric region, which projected slightly, but was not painful on gentle pressure. She had been always delicate, sickly, and childish in appearance. The bowels were usually relaxed, but irregular. She had menstruated once about ten months before she died. Her appetite was variable, and she often vomited her food. The tumour was gradually increasing in size. She suffered chiefly from weakness, and an occasional pain in the tumour. She seemed to rally under treatment at first, but severe pain came on in the tumour, and she died after a severe attack of vomiting. On examination, the cavity of the abdomen was found half-filled with semi-purulent fluid, and the stomach, duodenum, and part of the jejunum, were found distended with two hardened tumours, which turned out to be two masses of hair and string, weighing from eight to ten pounds, and matted together by the ingesta. The lower tumour, situated in the duodenum and commencement of the jejunum, consisted chiefly of string. No solid food could pass the obstruction, and the passage of fluid was almost obliterated. The girl had never been observed to eat string or hair, except when a child three or four years of age, but the habit had not attracted much attention. The obstruction had been going on for three or four years.

Dr. Seth Thompson briefly mentioned the case of a girl, who, during three weeks, had been passing portions of hair from the bowels. She was admitted for obstinate constipation, which had existed for eight or ten days. An operation was at one time meditated; but as there was no tumour present, and the seat of the obstruction could not be determined upon, it was abandoned. Three or four days afterwards, a quantity of hair passed away by the bowels in the evacuations, and this continued for three weeks. She said that she had not swallowed any hair for years before, but when thirteen years of age, had been in the habit of so doing. She made a tolerable quantity of urine. There was a tumour, of the size of the fist, situated about half-way between the umbilicus and ribs on the right side. She was now convalescent.

ANEURISM BY ANASTOMOSIS IN THE ORBIT. LIGATURE OF THE COMMON CAROTID ARTERY.

By H. Haynes Walton, Esq., F.R.C.S.

The author showed that Mr. Bell, who first described and named the disease, included under that head other vascular tumours, and several unallied growths. He then passed on to the true nature of aneurism by anastomosis, its characteristic of pulsation, when sufficiently superficial, and arterial *souffle*; and gave the particulars of a dissection of one, which consisted of tortuous arteries, communicating freely, and dilated into sinuses or canals, and the walls of which were thin. Allusion was made to want of knowledge of the accompanying veins, and the imperfect method of determining the question by injection alone. The particulars of his case were these. A girl, aged two months old, was brought to the Ophthalmic Hospital, with a prominent globe, without any indication of the true nature of the disease; but when four months old, the eye was more prominent, the conjunctiva was studded with large bloodvessels, and an arterial *souffle* was audible. Pressure lessened the protrusion for a few seconds. These symptoms increased rapidly, and the author tied the carotid artery. Not a single bad symptom followed, and in three days the reduction was so marked, that the lids were closed over the globe during sleep. Now, after several months, the child is well, and the eye very nearly like the other. The author dwelt on the fact, that the free anastomosis at such early life was no objection to the operation, because, although coagulation might not occur, there was a partially empty state of the vessels till the collateral circulation was fully established; and that the tone of the vessels not being lost, they adapted themselves to their reduced contents, and became confirmed in their diminished bulk. The usual cause of failure of tying the vessels going directly into such tumours, was pointed out; the seeming desideratum, when the ligature is to be useful, being, that the entire region should be influenced, and its vitality reduced. The author objected to the recorded cases of Mr. Travers and the late Mr. Dalrymple, being true aneurism by anastomosis, considering them to be common aneurism pointing out the difference; and concluded by showing, that when the ligature of the carotid is not in itself sufficient for a cure, it may be subservient to the success of other means, which, alone, would have been inapplicable or useless. A sketch of the patient was exhibited.

After the reading of the paper, a pause having ensued,

Mr. Hodgson rose and said that it was to be regretted that a paper of so great importance as that just read, should pass without discussion. There were one or two points connected with it, respecting which he should be glad of a little more information. He would inquire whether the tumour pulsated perceptibly without the aid of the stethoscope, what kind of ligature was used, and when it separated? He believed that no case was on record, in which so large an artery had been ligatured at so early an age for aneurism, as in the present instance. It was important to know that such an operation could be so early undertaken with safety. There did not appear to have been any ill effects produced on the brain in this instance; this was sometimes the case when the carotid was tied in older persons, but in other instances softening of the brain was the result. He had seen such cases occurring after the middle period of life.

Mr. Walton had not been satisfied that there was any perceptible pulsation in the tumour. Dr. Taylor had, however, distinguished a *bruit* in it on the application of the stethoscope, and one gentleman who had examined it, believed that he could detect pulsation in it. He was not aware of the exact time the ligature came away, for as the child kept pulling it about, it was cut quite close, and the wound kept partially open; but the mother had stated that it came away three weeks after the operation. He had not seen the child since. The ligature he had employed was that introduced into practice by Mr. Fergusson: it was composed of hemp.

Mr. Hodgson said, that in the paper a doubt had been expressed whether the cases related by Mr. Travers and Mr. Dalrymple were really instances of aneurism by anastomosis. He (Mr. Hodgson) had attended the case operated upon by Mr. Travers, both before and after the operation, and he did not think there was a doubt but that it was aneurism by anastomosis; consisting of many cells, some pulsating, some not, and made up partly of dilated arteries, and partly of sacculated veins. He did not see Mr. Dalrymple's case, but he had seen others similar to that of Mr. Travers, and of the same formation.

Dr. Snow remarked that there were facts connected with Mr. Walton's case which he thought were peculiar. He had expected that on the application of the ligature, the tumour would immediately have diminished in size. But this was not the case. When under the influence of chloroform, however, the tumour was materially lessened, but returned to its usual bulk directly the effects of the chloroform went off.

Mr. Hodgson showed that in Mr. Travers's case the tumour did not subside immediately on the application of the ligature, but gradually and slowly became smaller.

Mr. Barlow said that he had been struck by the observation made by the President, that most of the cases of softening of the brain which had come within his great experience, as results of tying the carotid artery, had happened after the middle period of life. This fact seemed to point at the existence of more or less arterial disease at the time of the operation. It would be of great interest to examine with proper minuteness not only the large, but also the small vessels of the brain, in cases of softening from this proceeding. With regard to the changes of the latter vessels, it seemed clear that their fatty degeneration led commonly to softening and apoplexy. He might particularly refer to the researches of Mr. Paget, in proof of the reasonableness of this view. Should the nutrition of the brain be impaired to the extent which a manifest and extensive degeneration of its small bloodvessels would imply, he could not help thinking that the organ would be in a most unfavourable state for so grave an interference with its circulation as the tying of the carotid would occasion.

Mr. Hodgson thought that the softening could scarcely be considered as the result of the deposit of fatty matter, as described by Mr. Paget. He had known a case in which, after the carotid artery had been tied, the brain softened and suppurated. There was no reason to think that the disease in the arteries, such as described by Mr. Paget, had taken place. Might not the ligature of the carotid so much interfere with the circulation in the brain as to produce softening, which, as Dr. Abercrombie had said, resembled the gangrene of other parts.

Mr. Streeter inquired what interval of time there was between the application of the ligature and the softening. He asked this question because he recollected Sir A. Cooper exhibiting the brain of the man on whom he first successfully performed the operation of tying the carotid. This man lived ten years after the operation, and then died of apoplexy, consequent upon an aneurism of the communicating branch which went to form the circle of Willis. It would be useful to watch the child whose case had been related that evening, to observe in what way the supply of blood to the brain was carried on.

Mr. Hodgson did not know how long, in the case he had mentioned, the softening took place after the operation.

After the discussion on Mr. Walton's paper, a communication from Mr. Pollock, "On the Morbid Appearances of nearly 600 Uteri," was commenced. The time of the Society having expired before the paper was half concluded, it was moved and seconded that the further reading should be adjourned until the following meeting. This proposition gave rise to some discussion. Mr. Pollock's paper had been posted in the library as the first to be read, and the result was that a great number of the more prominent fellows who practised obstetricy were present to hear and discuss it. Complaints were made that the papers had not been read according to the list published in the library: many gentlemen had come down at some inconvenience to hear it, and many who might have wished to be present at the reading of Mr. Walton's paper had stopped away under the idea that Mr. Pollock's paper would occupy the whole evening. The proposition for adjournment was carried *nem. con.*, thus affording a precedent for adjournments, which may be of advantage at some of the future sittings of the Society.—*Lancet.*

ORIGINAL COMMUNICATIONS.

CASES OF PULMONARY DISEASE.

By Edmund Sharkey, A.B., M.B., T.C.D., of Ballinasloe.

(Continued from p. 403.)

Case 12.—Jersey, June 5, 1845.—Mrs. Frend, ætat. 42, widow, has been long delicate; during last winter, while attending on her husband, who was dying of phthisis, she laboured under dyspnœa, pain of side, with racking cough, emaciation, and debility, with a very high pulse. Since then she has slightly improved. Yesterday I was called to see her, and found her spitting blood freely; pulse above 100, with a reverberation; pain of side. VS. ad deliquium. Blood is not inflammatory in appearance.

Present state.—Her chest exhibits the following *physical signs*:—Percüssion gives a generally clear sound, except over left supra-scapular region. Respiration exhibits the bronchial character chiefly in superior anterior right, where uneasiness is felt: puerile in superior anterior left. No bronchophony or râle discerned. In anterior inferior left there is a small circumscribed spot, very tender to the touch; heart seems normal.

6th. A blister, which was applied after the bleeding, has risen well; no blood in sputa; pulse continues quick. Tr. digital. gtt. xii. ter die.

9th. Pulse 108. Pergat c. tr. digital. sumat quaque, potass. nit. gr. xv., camphor. gr. v. ter.

10th. Feels easier; pulse 104; sputa now consist of white frothy saliva mixed with colourless mucus.

16th. Pulse 94; *urine* scanty, red; feet somewhat anasarcous; appetite improved.

℞ Ext. sarzæ c. liquoris potass. āā. ʒi.
Spt. junip. c. ʒss. in mist. ʒviii. cujus sumat ʒi. ter.

21st. Hæmoptysis has returned; pulse 108, full and strong. VS. ad ʒx. caused deliquium. Rept. potass. nit. and camph., and tr. digital.

22nd. Pulse 116, full; sputa still contain some blood; blood last drawn not buffed; clot soft.

23rd. Pulse 92, soft; sputa free from blood.

28th. Continues to improve; dose of tr. digital. increased to twenty-six drops; some giddiness and occasional drowsiness felt. Directed ung. ant. tart. to be rubbed to chest.

July 1st. Pulse 100, soft; a crop of pustules produced by ointment; expectoration difficult in the morning.

℞ Tinct. digital., liquoris potass. āā. ʒss. M. st. gtt. xxvi. ter die, ex decoct. fol. uvæ ursi.

5th. Better; pulse slightly irregular (94.) Pergat.

Oct. 21st. Has been pretty well since, but she has never lost her cough, which has been soft, till within a few days.

December. Cough rather more troublesome. M. pector cum ant. tart. gr. i., tr. op. camph. ʒi. ad ʒviii.

I shall not pursue the treatment of this case further.

The history of it shows the power which the combination of nitrate of potash and camphor exercises over hæmoptysis of this form, as I have before stated. This patient was alive in 1848, when I left the island.

Case 13.—St. Helier's, Jersey, May, 1845.—Foley, an Irish boy, ætat. 15, has been for four months ill, labouring under the alleged effects of a cold. *Present state.*—Considerable emaciation, dyspnœa, cough, anorexia, debility, and very anæmic appearance. *Physical signs.*—Percussion does not elicit any dull sound, but there are extensive bronchitic râles.

℞ Sapon. moll. g. ammoniac āā. ʒi.
Ol. junip. gtt. v.
Potass. hydriod. gr. xxiv.
Syr. zingib. q. s. M. Ft. pil. xxiv. st. i ter die.
Liniment. ac. acet. et terebinth. (Stokes's formula) to the chest.

No benefit having accrued from the treatment last prescribed, I ordered calom. gr. ss., ipecac. gr. i. bis die, fric. ung. iodinii sub axilla o. n., and vesic. inter scapulas. Stokes's embrocation was continued, and he took a decoction of fol. uvæ ursi.

June. Considerable improvement. On the 28th of this month, on making a more accurate examination, I found a decided comparative dulness on superior right side anteriorly and posteriorly, with corresponding feeble respiration, while the left presented the puerile character; no râle; action of the heart very strong, and felt over a large space, and heard all over right side; a distinct bruit de soufflet heard between the shoulders and along the course of the spinal column (though not heard in the proper cardiac region), accompanying a single sound, hence probably existing in the aorta; cough gone; complains chiefly of short breath on any exertion; general health and appetite improved. Tinct. digital. gtt. xii., ex decoct. uvæ ursi ter die.

October 25th. Improved greatly; cough and dyspnœa continue, also palpitation, to which he had been liable; there remains considerable debility with occasional swelling of ankles; his parents being very poor, are unable to procure him proper nourishment.

December 11th. On inquiry to-day, I have heard that his health has been so far established that he has this day gone to sea.

February, 1848. Is at home for some months, and has grown very tall, but is still short-breathed.

Case 14.—St. Helier's, Jersey, August 12, 1847.—Miss R——, ætat. 30, a Scoto-Indian, of consumptive family, has been for many years—indeed ever since childhood—in delicate health. Has lately returned from Madeira, where she spent three years. She has had cough, pain of side, hæmoptysis, and all the symptoms of consumption, together with increased action of heart, tendency to syncope, and suffocative sensation, and is obliged to sleep with head and shoulders elevated. She has passed through the hands of many eminent physicians, had a variety of treatment, of which the principal has been, topical bleeding, blistering, stimulating liniments, with the internal use of anodynes—viz., morphia, hyoscyamus, and hydrocyanic acid, and digitalis, variously combined with expectorants in minute doses. Says she did not find Madeira to agree with her latterly, and during her last winter there had a severe chest attack, from the effects of which she has never since quite rallied. She has since resided for a short time in the Isle of Wight. *Present state.*—Nervous excitability excessive; acute pain of chest with palpitation (respirations sometimes amounting to 84 in the minute); irregular hectic; loss of rest; digestion and uterine functions regular; appetite very bad; pulse 104, variable. *Physical signs.*—Dull percussion extensively in cardiac region; respiration feeble over every part of chest without any accompanying râle, and percussion is clear except in the situation above indicated; the left subclavicular region seems sunk in; cardiac sounds heard with excessive clearness over nearly entire chest anterior and posterior. Three points at which there is such exquisite tenderness as scarcely to admit the lightest pressure of the stethoscope—namely, upper end of sternum, below the margin of left ribs near xiphoid cartilage, and under clavicle. Prescribed a mixture containing vin ipecac. and muriate of morphia (i. gr. ad ʒviii.), and a blister to the side, with milk diet.

15th. No relief. Appl. hirud. iii. 16th. No relief; cough harassing; copious perspiration; pulse 92; respirations 76.

17th. Applied a large blister between the shoulders with some benefit, respirations having fallen to 60, but the respite was short; the respirations rose again in the evening.

℞ Camph gr. v.
Potass. nit. gr. x.
Tinct. hyos. gtt. xxx.
Digital. gtt. xx.
Mucilag. aq. m. pip. āā. ʒiiiss. st. haust. h. s.

18th. But little relief; pulse 104; respirations 84; debility great. Appl. emplast. belladon. ampl. p. d.

℞ Ext. belladon. gr. vi.
Conii gr. xii.
Hyos. gr. xii.
Pulv. ipecac. gr. vi. M in pil. xii. divide.

19th. An attack of dysentery. 20th. Dysentery checked by m. cretæ c. tr. op.; dyspnœa and pain of side severe. Appl. empl. vesicat. p. d. 21st. Pulse 106; respirations 60. Linim. acid. hydrocyan. gtt. i. 22nd. Pulse 100; respirations 60. Linim. acid. hydrocyan. gtt. iii. 24th. Slight return of appetite; pulse 100; respirations 52. 25th. Return of dysentery. Pills of plumb. acet. and op. m. cretæ c. tr. op. 27th. Pulse 98; respirations 44. 28th. Pulse 84; respirations 52; spinal tenderness. Ap. empl. belladon. spinæ dorsi. 30th. Uneasiness of chest followed by slight hæmoptysis.

September 3rd. Hæmoptysis continuing, three leeches were applied to the dorsum of foot. 4th. Intense headache causing great prostration. This continued during two following days. Hæmoptysis checked. 23rd. Return of hæmoptysis.

October 6th. Rather better since last report, but to-day hæmoptysis has returned. To take tr. digital. gtt. xii. three times a day, and pills containing plumb. acet. and opium.

14th. Has been for some time troubled by distressing nausea, which to day brought on discharge of some florid blood from the lungs.

January, 1848. She continued to suffer a series of alternations like the preceding, till this month, when she was brought to death's door by violent cough, so incessant as almost entirely to preclude sleep, and occasionally make suffocation even imminent, compelling her to remain nearly erect; the paroxysms being evidently accompanied by spasm of the glottis. She suffered from hectic fever, with very profuse perspirations. The paroxysms were relieved in some measure by morph. acet. et spirit. æth. sulph. The only nourishment she took was a little tea and broth.

It is needless to pursue this embarrassing case through its labyrinth of alternating symptoms, ever varying, and compelling an incessant change of remedies; the pectoral symptoms, when somewhat relieved, giving place to gastric and intestinal; these again to colliquative sweats, and all being complicated by a strong admixture of hysteria, evidenced by the distressing headaches and the otherwise unaccountable disproportion between the number of the pulse and that of the respirations. The case has, indeed, been detailed thus minutely, partly with a view to give the younger portion of the profession a specimen of the sort of cases they may occasionally expect to meet, and partly for the purpose of showing the joint effect of medical treatment and change of climate on an amount of thoracic disease which, but for the latter, would probably long ago have terminated fatally. This lady had the temerity again to try an Edinburgh winter, but has, I am since informed, made her escape to the south of France.

THE DISEASES AND PHYSICAL PECULIARITIES OF THE NEGRO RACE.

By S. A. Cartwright, M.D., of New Orleans.

In the report on the diseases and physical peculiarities of the negro race, read before the Louisiana State Medical Society, and published in the *New Orleans Medical and Surgical Journal* of May last, I briefly enumerated some of the more striking anatomical and physiological differences, separating the negro from the white man. Attention was also called to the fact, that the same medical treatment which would benefit or cure a white man, would often injure or kill a negro, because of the differences in the organic or physical characters imprinted by the hand of Nature on the two races. It was not deemed necessary in that brief paper to refer to authorities to prove the facts enumerated, which are just as well known and established in that branch of medicine, embracing comparative anatomy and physiology, as the size and motion of the planets in astronomy.

The report was not drawn up to meet objections coming from those persons who have never made comparative anatomy and physiology a special study. But as they have made objections to it, and are inclined to look upon the facts it sets forth as a farrago of nonsense, or at least as very questionable assertions needing proof, the object of this paper is to give them proof. This trouble might have been spared, if the comparative anatomy and physiology of the different races of mankind had not been strangely neglected in the course of instruction in the medical schools of the present day. In Europe, where there is but one race of mankind to treat, comparative anatomy and physiology are of no great practical importance. Nevertheless those branches have been extensively cultivated, particularly in Germany and France, by the greatest men that have ever adorned the medical profession. In this country comparative anatomy has been very much neglected, and comparative physiology and therapeutics more so. Our northern states, like Europe, contain but one race of men (excepting a few free negroes), and all the medical instruction of the books and schools is confined to that one race. But here in the south we have two distinct races of people, living in juxtaposition in nearly equal numbers, differing widely in their anatomy and physiology, and consequently requiring a corresponding difference in their medical treatment. Yet when it was asserted in the report, that the Queen of England's medical advisers, without a knowledge of the physical difference between the Ethiopian and Caucasian, would not be qualified to prescribe for a negro, great exceptions were taken to the remark by those who are aware that different temperaments, as the sanguine and phlegmatic, require important modifications in medical treatment, but were not aware that Cuvier, Ebel, Sœmmering, Malpighi, Pechlin, Mecklin, Albinus, Stubner, Virey, and many other illustrious men, have long ago demonstrated, by dissections, so great a difference in the organization of the negro from that of the white man, as to induce the majority of naturalists to refer him to a different species having a different origin.

So great is the difference in the medical treatment demanded by the peculiar organization, physiology, and habits of our black population, that very learned physicians from Europe and the northern states, on first coming south, have felt and acknowledged their incompetency to treat their diseases successfully, until they have had time to make themselves acquainted with their peculiarities. The owners of slaves consider it safer, in most cases, to trust to the empiricism of overseers, rather than to the regular doctors who are new comers, practising on the false abolition theory that the negro is only a lamp-blacked white man. There is nothing to prevent young physicians, new comers to the south, from treating negroes successfully, if they were to study their diseases, their anatomy, physiology, and pathology, with half the care they devote to the white paupers in the northern and European hospitals and almshouses.

On coming south, they find no such class of persons as those whom they have mostly studied to treat. They not only find no complaints arising from want of food, fire, clothing, and the common comforts of life, such as those they have been accustomed to see in the hospitals, but they find one half of the population composed of a people whose anatomy and physiology is a sealed book to them. Although the every-day experience of the southern people proves that Nature has made so great a difference between the white and black races, as to make it absolutely necessary for the safety of the state and the well-being of society, that the latter should be subjected to different laws and institutions from the former, yet the text books of the northern medical schools contain not a syllable to show what that difference is, but advise the same rules and principles and the same therapeutic agents, as if there was no other race of mankind than that inhabiting the northern states. The popular error prevalent at the north, that the negro is a white man, but by some accident of climate or locality, painted black, requiring nothing but liberty and equality, social and political, to wash him white, is permitted to go uncorrected by the northern medical schools. This error can be and should be corrected at the dissecting table, by reviving comparative anatomy and making it an essential part of a medical education. If the northern schools will not correct it, the southern schools, instead of being, as they now are, northern institutions located in the south, using the same text books and echoing the same doctrines, should take upon themselves its correction, and have their own text books, containing not only the anatomy, physiology, and therapeutics applicable to the white race of people, but the anatomy, physiology, and therapeutics of the black race also.

As soon as they do this, the empire of medical learning will come south, where the study of two races of people will give students better opportunities of acquiring knowledge than the one race at the north. Physicians will also reclaim the practice among three millions of people that the overseers have mostly got. It will be for the interest of the planters to employ physicians, instead of overseers, to treat the diseases of their negroes, as soon as they properly qualify themselves for this branch of southern practice. A southern country physician never wants practice, who is properly qualified to treat the diseases of negroes. It is only those medical men whose knowledge is confined to the diseases, the anatomy, and physiology of only one race of men, as contained in the northern horn-books of medicine, who are superseded by overseers and empirical practitioners. So little attention has been paid to the anatomy and physiology of the negro race, that when it was mentioned, among other peculiarities of the negro, that his blood was *blacker* than the white man's, it was supposed by those physicians who have paid no attention to comparative anatomy and physiology, that I was making random assertions requiring proof, instead of reiterating truths that have been known for centuries, needing no other proof than the perusal of works of the highest authority in medicine. Thus Malpighi, the celebrated anatomist of *rete mucosum* memory, says—"La couleur noire reside non seulment dans le fluide qui colore le tissu muqueux mais encore *le sang*, la part corticale du cerveau et plusieurs autres parties internes du corps impregnées d'une teinte noire, et ce qui a été remarqué également par d'autres observateurs." Here is not only the authority of Malpighi in proof of the darker colour of the negro's blood and the impregnation of the brain, membranes, and other internal parts of the body with a darker hue, but likewise his testimony that other observers had remarked the same thing.

J. F. Meckel (see vol. xiii., p. 69, Mem. Acad., Berlin) says that not only the blood, but the bile and cortical part of the brain, are of a darker colour in the negro than the white man. According to his authority, the negro is not only a negro on the skin, but under the skin. The words of that great comparative anatomist are:—"Le nègre n'est donc seulment nègre à l'exterieur mais dans toutes ses parties et jusque dans les plus profondement situées."

N. Pechlin, in a work entitled "De Cute Athiopum," and Albinus, "Diss. de sede æt causa coloris Athiop.," have remarked, that not only the blood but the muscles of the negro are of a darker red than the white man's. These authors also state, that the membranes, tendons, and aponeuroses, so brilliantly white in the Caucasian race, have a livid cloudiness in the African. J. J. Virey, one of the authors of the great Dictionary of the Medical Sciences, Paris, says (vol. xxxv., p. 388) that the flesh of the negro differs in colour from the white man's, as the flesh of the hare differs from the rabbit. This author confirms everything said in the report about the darker colour of the blood, membranes, smaller size of the brain, and larger size of the nerves in the negro than in the white man.

The celebrated anatomists, Sœmmering and Ebel, also speak of the darker colour of the blood, muscles, &c. These anatomists confirm every word in the report about the brain being smaller and the nerves larger in the black than in the white race. MM. Cuvier, Gall, and Spurzheim, also found the capacity of the brain about a ninth less in the negro than in the European. Samuel George Morton (see "Observations on the size of the brain in various races and families of man," Philadelphia, 1849) has ascertained that the negro's brain is nine cubic inches less than the white man's. Lately some attempts have been made by British abolitionists to distort the facts of science by representing the African brain as equal to the European, and the mind of the former equal to the latter. A certain Dr. Robert Bently Todd of King's College, London, in a work on the "Anatomy of the Brain, Spinal Cord, and Ganglions," 1845, London, endeavours to throw some doubt and uncertainty on the received and well-established facts in regard to the inferiority of the negro's intellect, the comparative smallness of the brain, and the larger size of his nerves. Also, James Cowles Prichard, another British writer, author of "Researches on the Physical History of Mankind," in five volumes, London, 1844 and 1850—an abolition work, disguised under the pretence that the authority of the Bible would be impeached if the great differences that natural historians and comparative anatomists professed to have discovered in mankind, were not called in question. Prichard, in the preface of his work, admits that the weight of authority in the learned world is altogether against his conclusions. His conclusions, not following from the premises, prove that scientific truth was not the object of his work; that it was not written for learned men, but to cast dust in the eyes of sophomores and the vulgar, to prevent them from seeing the truth on the slavery question. He pretends to be very fearful that the learned anatomists and naturalists, unless held in check, will bring the scriptures into disrepute. He does not seem to be aware of what Cardinal Wiseman justly observes, that "it is only half-way science and half-way truths that militate against the authority of the Bible." The whole truth, when brought out, and perfect freedom of science to pursue its investigations untrammelled to its terminus, have, in every instance, demonstrated the truth of the Bible, while imperfect investigations and the omission of the truth, or the tying science down to the narrow interpretations of Biblical commentators, have generally led to scepticism and infidelity.

Prichard seems to be so much afraid, that if the physical differences which Malpighi, Sœmmering, Cuvier, and other comparative anatomists, have discovered in the negro's organization, approximating him to the monkey tribes, be admitted, the Bible will be invalidated; and he has taken much pains to try to overturn their general truths and principles by partial exceptions. He adduces instances to prove that white persons have turned black in whole or in part, and that the negro's skin has in some instances turned white; but he ought to know that the change of colour in all such cases is the effect of disease. Dr. Rush was so much afraid that the black skin, thick lips, and flat nose of the negro would invalidate the Mo aic account of the creation of man, and the unity of the human family, that he published in the Medical Repository (vol. iv., p. 409) some suggestions, attributing the black colour, thick lip, and flat nose to a disease resembling leprosy. But observation proved, that so far from the black colour being caused by disease, the blackest negroes were always the healthiest, and the thicker the lips and the flatter the nose the sounder the constitution. Both Prichard and Todd labour to prove, by a few cases, exceptions to the general rule, that the brain of the negro and his mental capacity are equal to the white man, lest the scriptures be invalidated, if an inferior slave race be admitted. They overlook the fact, that the Mosaic history distinctly specifies an inferior slave race of people called Canaanites, Gibeonites, &c., and that these people were reduced to slavery and their country taken from them by Divine command. In aiming to overthrow Cuvier's specific characteristic traits of the negro's organization, Prichard did not seem to be aware that Cuvier and Moses agree exactly in their definitions, both defining the negro as the "knee-bender." (See Cuvier Mem. du Museum d'Hist. Nat., tome iii., p. 159.) Where the anatomical structure of the negro's knees is brought forward by the greatest naturalist the world ever saw as a specific mark of difference between him and the white man, and also the inferiority of intellect from the diminished quantity of brain. Exactly the same things are set forth in the inspired writings, by the name given to the Canaanite or Ethiopian race; the Hebrew word *Canah*, from which the word Canaan is derived, literally meaning "knee-bender, crushed or broken in mind," tantamount to Cuvier's race of men with weak and timid mind, and "les genoux à demi-flechés." Hence it would not appear that the Bible does not stand in need of Todd, Prichard, and other British abolitionists, to support its truth by special pleading, or by dodging the truths of science. Both Todd and Prichard are compelled to admit that the negro's blood is darker than the white man's, but they deny that the brain is of a darker hue, as Meckel, Pechlin, Albinus, Malpighi, and many other comparative anatomists, have asserted. They quote three dissections made by Sœmmering, where the difference in colour was not apparent, but rather unnaturally white. They concealed the fact, or did not know it, that disease tends to obliterate the dark colour that pervades the negro's organization, giving the deeper seated parts an unnatural whiteness. Thus, as the report sets forth, in negro consumption the mucous membranes, instead of being dark, are paler and whiter than in the Caucasian race. It would be very unfair to adduce those cases of whiteness of the gums and mucous surfaces in diseased or consumptive negroes, to disprove the fact of darkness being the general rule. Todd and Prichard labour much to call in question the facts heretofore observed by comparative anatomists, that the nerves leading from the brain are larger in proportion than in the white man. Yet they are forced to admit that the negro's sense of smell and hearing is more acute.

The auditory and olfactory nerves must therefore be larger, or the physiological law of nervous development being proportional to activity of function, must be denied. Those, likewise, who deny that the nerves of the stomach are no larger in the negro than the white man, are compelled to admit that his digestive and assimilating powers are stronger, which is the same thing as to admit that the nerves of organic life are larger. Everything asserted in the report in regard to the negro's eye, and his bearing sunlight without a covering on his head, will be fully confirmed by reference to Sœmmering's work entitled "Icones Oculi Humani," where it is distictly stated that the plica lunaris, in the inner canthus of the negro's eye, is anatomically constructed like that of the ourang outang, and not like that of the white man. Virey confirms every word stated in the report about the small size of infant negroes' heads, and the sutures being closed. (See Dict. des Sci. Méd., vol. xxxv., p. 401.)

In regard to the bones of the negro being harder, whiter, and containing more phosphate of lime than those of the

white man, naturalists universally agree. Herodotus mentions the greater hardness of the Ethiopian skulls; proving in that respect, at least, that the negro is the same now that he was two thousand years ago. The Crania Ægyptiaca prove, as Morton justly observes, and has placed on the titlepage of his catalogue of skulls, that "the physical organic characters which distinguish the several races of men are as old as the earliest records of our species." Abolitionism is founded in ignorance of those physical differences that science proves.

A radical reformation is greatly needed in our system of education, medical and political, which is so defective as to lead to the fatal error that there are no physical or organic characters in the Ethiopian organization different from that of the European.

In medicine, a blundering practice, in ignorance of the negro's anatomy and physiology, is not the only evil of this defective system of education. The peculiar phenomena, indicating debasement of mind, necessarily springing from this difference in organization, are attributed by the ignorant and mischievous political demagogues of the north to the effects of southern slavery. But it could easily be shown by anatomy, physiology, and ethnographical investigations, that the debasement of mind falsely attributed to southern slavery arises from causes imprinted by the hand of Nature on the sons of Ham, so far back as the time when the catacombs of Egypt were constructed. The vulgar error, that there is no difference in the organization, physiology, or psychology of the African, and that all the apparent difference arises from southern slavery, is the cause of all those political agitations which are now threatening to dissolve our Union. The knowledge to correct this most mischievous error, which has already split nearly every denomination of Christians in the United States, is to be found by cultivating comparative anatomy, physiology, history, and ethnography,—*Charleston Med. Jour.*

ON SPONTANEOUS SMALL-POX.

By Dr. Purple of Greene, United States.

What the combination of causes is, on which the spontaneous appearance of the small-pox depends, it is impossible definitely to determine. The subtlety of all the phenomena of this disease lies hidden in the recesses of nature. and far beyond the ken of human vision. The physical condition of the system *before* its advent, that renders it susceptible to its invasion—the change that takes place *after* it has presented itself, that renders the system nearly or quite exempt from future attack—as well as the *modus operandi* of the contagion itself, are all topics that the human senses cannot grasp, nor finite reason clearly elucidate. Hence the extreme difficulty of proving a negative, and showing conclusively that the disease in a given case did not proceed from contagion. It is only by a faithful examination of all the circumstances in a series of cases that we can arrive at reasonable deductions on this subject, and form rational conclusions for our practical advantage. To this end I venture to enter this hitherto untrodden field, and relate a few instances of the spontaneous manifestation of the small-pox that have fallen under my own observation, in the hope that others, whose field is more extensive, will take up the subject and more thoroughly investigate the phenomena on which its truth or falsity depends.

The first case to which I shall allude occurred in the town of Greene, near Coventry, in the month of January, 1831, in the person of Mr. Horton, aged 40. He had enjoyed uninterrupted health, with the exception of an ulcer on the tibial side of one of his limbs, which had annoyed him for some years. At the period of the advent of the disease, he was at work, with no other company than a young lad, in a small factory for the manufacture of rakes, some quarter of a mile from the highway. His wares were carried away in the summer, and no stranger had been at the shop. He had not been from home in many months, and his taciturn temperament led him little into society, at least with strangers. In this case the premonitory symptoms were well marked, and of the ordinary duration; indeed, all the symptoms were perfect, and such as indicated unusual severity. They ran on until the 12th day of the eruption, and terminated fatally. Every exposed person who was subject to the disease received the contagion; and many who had had the variolæ vaccinæ, or the vaccine disease, were more or less afflicted by it. There were about forty well-marked cases that arose from exposure to this patient, three of which proved fatal. Public attention was early called to the subject, and in the end, became very much excited in relation to its origin. Professional inquiry was had in requisition to fathom the mystery—the populace raised high its voice, and in entire confidence that it could not appear except by contagion, every one had a cause, Imagination was on tiptoe—fear expanded wide the ears of credulity—and malignity, with its criminating tongue, lent its aid to investigate the origin of the disease. Nor was this all. Courts of justice, with their talented advocates, were called in to unravel the mystery; but all in vain. After a patient investigation for two years, with the attrition of conflicting opinions, all parties were forced to the conclusion that its spontaneous manifestation was the only rational mode of accounting for its appearance, and that contagion could have had nothing to do with its origin.

Case 2.—The next case to which I shall call your attention, occurred at the same time with the foregoing. It presented itself on the height of land between the Chenango and Unadilla rivers, in the town of Norwich, and fell under the care of my friend Dr. Royal Ross of New Berlin. The patient was a child that lived in a very secluded place, and so far as the most scrutinizing investigation could determine, was entirely independent of a foreign source. The symptoms were severe, following each other in regular succession, and gave unmistakable evidence of the diagnostic character of small-pox. Contagion followed, and a number of individuals had the disease before sanitary regulations could be brought to bear to arrest its progress. It is proper to remark, that quite a number of cases of varicella had shown themselves for some miles around; they appeared in a mild form, were not traceable to each other, nor did the variola and varicella mutually produce each other. It appeared as though they were concurrent, manifesting an endemic atmospheric influence.

Case 3.—The next case to which I shall refer presented itself in the town of Pitcher, at the extreme western bounds of our county, and fell under the eye of Dr. D. McWhorter. It occurred the same winter, and within three days of the two foregoing cases. The patient was an adult, and lived in a retired part of a rural country. It presented all the characteristics of a spontaneous case of small-pox. Thorough investigation was had at the time to demonstrate its foreign origin, but in vain. It resulted in an entire conviction on the part of all, that it did not arise from contagion. The diagnostic manifestations were perfect, the symptoms ran the usual course, and when the secondary fever appeared it proved fatal. Quite a number of persons contracted the disease by direct exposure, and although no evidences of the minor exanthemata had *preceded* it, a number of cases of varicella *followed* it. They appeared in an epidemic form, and could in no instance be traced to exposure to the variola. These three cases came to my knowledge at the time they existed, and were subsequently duly investigated in reference to a legal inquiry. The facts, so far as they involve their spontaneous character, were amply sustained by medical and other testimony, and living witnesses, both in and out of the profession, could now be obtained to substantiate them. It may be thought that the advent of these three cases, so near each other, and at the same time, would indicate that they had a common contagious origin. But it should be borne in mind that they occurred some thirty miles from each other; that they appeared in midwinter, when the snow was deep and drifted; that they all presented themselves in the most sequestered locations; while in our thoroughfares and villages the inhabitants were entirely exempt from the disease.

Case 4.—The next and last case to which I shall allude occurred at Chenango Forks, seven miles from our village, the first week in January of the present year. The disease attacked a child about four years of age, without the slightest evidence of exposure. I saw it, in company with my friend and neighbour Dr. A. Willard, about the fourth day of the eruption, and although the premonitory symptoms, with the attendant fever, were mild, and the eruption in consequence rather imperfectly developed, yet to the experienced eye, there was not the least difficulty in distinguishing its diagnostic character. One who had seen and been familiar with the small-pox, could not but see all its essential characteristics in the case before us. This was clearly and unequivocally declared. But the attending physician and many of the relatives of the patient could not, or would not, believe it to be such. Their reason was, that the child had not been exposed to contagion. They were under the shadow of that delusion which I am endeavouring to disperse, and could not believe in opposition to popular opinion that the small-pox could spontaneously appear in the human family, and particularly that this loathsome disease should appear in a member of their own household. They were all ready to declare that if there was a possibility for it to have been *exposed*, or if it had occurred in a city, they could believe it to have been a mild case of small-pox; but as it had neither of these advantages, and had presented itself without legitimate parentage, they heeded not our admonition, stoutly denied its character, ridiculed our diagnostic opinions, and governed themselves accordingly. The child died about the tenth day of the eruption, and was buried with all the formalities of a country funeral, even to the exposure of the body to the gaze of a sympathizing populace. A few days after, and before contagion had appeared, I announced in my place at the annual meeting of this Society the nature of the disease, and the evidence of its being of a spontaneous character. On my return, the seed that had been sown and scattered to the four winds of heaven, had taken root and exhibited signs of germination. It spread extensively. Some twenty-four cases arose from the first subject; some of them were mild, others assumed the most appalling forms; four proved fatal, including the first, and the balance are living evidences of the spontaneous appearance of small-pox, and bear the marks of the disease indelibly engraven on their foreheads.

The attention I have been able to give this subject, with the uncontrovertible facts that have fallen under my own observation, have clearly established to my mind the following positions:—1st. That small pox, as well as all other contagious diseases, does occasionally present itself among us without specific contagion. 2nd. That the physical system is so constituted that it is obedient to certain organic laws, and among these is the generation and development of every disease to which each particular animal is subject. 3rd. That there are seasons when atmospheric causes render the system more obnoxious to the invasion of these diseases, either by spontaneous development, or increased susceptibility to contagious influences. This was particularly the case in 1831, when there was a wide-spread exanthematous tendency, and very many instances of spontaneous appearance. 4th. As the higher latitudes are more subject to small-pox than tropical regions, the coldest seasons of the year are the most favourable for the generation of this disease; and in every instance where we have known a well-marked case of spontaneous appearance, it has occurred in the coldest weather, when the thermometer was nearly or quite to zero. 5th. That when small-pox appears without contageon it is usually severe, or at least it is apt to attack those who lack recuperative energy, or are illy qualified to develop the disease in perfection, and conduct it to a favourable issue; hence, independently of the treatment they receive, they are very liable to prove fatal. 6th. That when it thus appears, owing to the epidemic or endemic cause that produced it, the whole populace, including those that have been protected, are more liable to be affected by it, than when it has been received by contagion. Indeed, the exanthematic tendency renders the vaccine disease more severe than at other times. 7th. That there is a constant and progressive change manifest in the human family in relation to susceptibility to small-pox. This is apparent in the fact that the disease is more mild than it was some centuries since, and independent of treatment, the mortality in a given number of cases is much less than formerly. It is manifest by the appearance of varioloid after vaccination, which seldom or never appeared in the early experiments with this preventive; and there is no doubt but that it appears spontaneous more frequently than in the early recorded history of the disease. 8th. That vaccination is the only safe prophylactic, and independent of any deterioration in the vaccine matter, the change above referred to renders a second vaccination more necessary than formerly. 9th and lastly. That small-pox is not always attended by the minor exanthemata, and when they do appear together, it is as apt to *precede* as to *succeed* them, as was manifest in three of the above-mentioned cases.—*New York Jour. of Med.*

VICARIOUS MENSTRUATION.

Dr. Lecomte, of Eu, in France, has published, in *l'Union Médicale*, a case of an extraordinary description, of which we shall offer a short outline. The subject is a servant girl, aged 29, of apparently good health; she had never menstruated, and for the last seven years had experienced flushings and heat in the face, these symptoms recurring every four or five weeks. At these periods she likewise complained of severe lancinating pain in the right thigh, and sometimes in the leg and foot, the whole leg then becoming extremely tender to the touch.

Towards June, 1842, these phenomena increased in intensity, the patient became very weak, the abdomen felt tense, tympanitic, and tender, and she could no longer pass urine. Dr. Lecomte prescribed leeches to the hypogastrium, and prolonged hip-baths. The urine flowed a little; but at last the girl was persuaded to submit to the catheter, and a large quantity of dull and fœtid urine was drawn off.

Now began a series of strange phenomena. The bladder, uterus, stomach, and rectum began to throw off what the patient called *balls*; these were pieces of membrane, or rather membranous casts, white, dense, and covered on one side with gelatinous matter. The vesical casts were somewhat large, as she was obliged to extract them with her fingers. On a former examination the internal organs of generation could hardly be properly explored, as the hymen was unbroken and rather tense, but the casts now came per vaginam, and the patient being obliged to dilate the parts herself, in order to give passage to the membranous formations, it was found on examination that the os was pervious, and the cervix of the normal size, though tilted backwards. Here the casts assumed a tubular shape.

The stomach now became very irritable, and a great abundance of glairy matter, mixed with pseudo-membranes, was thrown up. The vomiting now and then was of a purely sanguineous character, and in the coagula ejected an ascaris lumbricoides was noticed. The patient stated that she had likewise seen such parasites in the matters which had been expelled from the vagina. Diarrhœa supervened a little time afterwards, and in the dejections the same pseudo-membranous products were observed.

After a few weeks' respite, the symptoms recurred with renewed intensity; all the above-named organs secreted the same membranous products, but the uterus was evidently the most active. In one day Dr. Lecomte extracted ten casts, of a red colour, from the vagina; they were rolled up, and exhibited now for the first time. One of these presented on one side an infundibular shape, which made the medical attendant suspect that the membrane must have been formed in close vicinity to the Fallopian tube.

The ejection of the casts was always accompanied by much pain, the latter being sometimes so intense as to cause the patient, who was far from being pusillanimous, to roll about in the bed with agony. The sanguineous

flux was now suddenly transferred to the ears; these organs discharged each about a tumblerful of blood; vomiting of the same fluid came on a few days afterwards, and the casts were again ejected from the stomach, intestines, bladder, and uterus. When these symptoms had ceased a great improvement was noticed; the patient gradually became stronger, and from 1842 to the present time, the girl has experienced no uneasiness but dysuria every two or three months, except in July, 1843, when the most complete relapse occurred. The author does not say whether any amount of regular menstruation has appeared since the casts are no longer secreted. This is a great omission. The pseudo-membranous products were examined by M. Mialhe, and were found to be composed principally of albumen.—*Prov. Jour.*

REMOVAL OF SIXTY-FIVE TUMOURS IN ONE OPERATION.

By W. H. Reynale, M.D., of Dansville, United States.

Fourteen months ago, I was desired to see a son of Mr. Murray, aged 10, of Ossian, Allegany county, eight miles from this place. I found the boy small of stature, very pale, with a large tumour on the left side of the neck. He looked like a child with two heads, only the tumour was the largest. It occupied the whole space from the root of the ear to the acromion process of the scapula; filled up everything from the spinous processes of the cervical vertebra to the clavicle, run from the ear along the lower side of the cheek and jaw bone, to beyond the trachea on the opposite side of the neck; so that in fact it filled up and occupied a little more than the entire space on the left side of the neck, and threw the head on the opposite shoulder. I removed the entire mass, with the assistance of Drs. Endress and Patchin: we took out sixty-five distinct tumours, attached together by a cellular substance, from the size of a goose egg and larger, down to that of a marrowfat pea; *they were of a fatty substance I think.* They filled a half gallon jar after their removal. The patient recovered so as to enjoy tolerably good health for eight months, when a number of small tubercles began to form around the margin of the old extirpated tumour—most were on the shoulder, some near the ear, and a few near the clavicle and spine; all were on the circumference, and none on the cicatrix. He soon after this began to complain of a pain in his left side, just below and beneath the false ribs. His father fetched him to my house; upon an examination I found a tumour of a large size under and coming out from beneath the ribs, and quite painful to the touch. I told the father I could do nothing for his son, the disease was of a malignant nature, and that he would die. He lived twelve months from the time of the operation, and died. His father sent me word at the time of his death, according to agreement; but in consequence of my being from home at the time, I did not get the information, and no post-mortem examination was made, which I much regretted.

We kept our little patient fully under the influence of chloroform during the whole of the operation, which lasted nearly two hours, but fully one half of the time we desisted from cutting, and applied restoratives, as the patient sunk low. You may probably think we used the chloroform too long; but we weighed the chances of the patient in our own minds, for and against the influence of chloroform on his nervous system, before the operation. We believed he would sink under the influence of the operation without the use of the chloroform, and that he could but die with its use. We decided, after mature consultation, to use the chloroform—it did, upon the whole, well—the patient had no knowledge of pain.

After the *entire mass externally was removed*, we discovered that a tumour of the size of a black walnut, was lying under the clavicle; this was removed without much difficulty; then another was discovered lower down, of about the same size; this I seized with two tenaculums, one in each extremity of the tumour—an assistant held them firmly and made a little pressure upwards, when partly by dissecting, and partly with the handle of the scalpel, and partly with my fingers, I succeeded in extracting this also; but still there was another one of the same magnitude, lying yet deeper and beneath the last one—this lay below the second rib; it was also seized with two tenaculums, and firmly held by an assistant, until partly with the handle of the knife, but mostly with my fingers, and a very little dissection with the knife when it could not possibly be avoided, I succeeded in getting *it all out*—no more could be felt. It is unnecessary to describe the situation of the patient, from day to day, during his convalescence; for the first few days he vacillated between hope and fear, but the powers of nature came to our assistance, and the patient recovered so far as to enjoy tolerably good health for eight months; ate and slept well, the countenance improved, and he looked better than he had for two years before the operation. The head resumed its natural position, and the rotary motion was good. The patient went to school some two or three months during this time. This enormous mass was only two years in growing; when it was first discovered it was of the size of a filbert, or smaller, and situated directly at the root of the ear. Mr. Murray says many applications were used to discuss the tumour, but they all (he thinks) hastened its growth.—*Buffalo Medical Journal.*

We copy the above as a specimen of heroical operative surgery, and more for the amusement than the instruction of our readers. Although it comes from the "far west," we do not copy it as a feat peculiar to that part of the world. Such are now and then performed on this as on the other side of the Atlantic.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, FEBRUARY 4, 1852.

PRESENT CONDITION OF THE DISPENSARY SURGEONS.

We have had several communications relative to the present unsatisfactory state of existing arrangements for affording medical relief to the poor. The resources of the expiring Dispensaries are nearly, if not altogether, exhausted; while the machinery of the new institutions has not yet been put into working order. It matters little where the fault lies, if fault there has been, the remedy it is that concerns us. The act, passed on the 7th of August, came into operation on the 1st of October, yet the Medical Commissioner was not appointed until the 11th of November, and the Inspectors not till the latter end of December. It is no wonder, then, that the division of 163 unions into Dispensary Districts, and the settlement of salaries, should still remain unfinished, and as we fear with little prospect of speedy consummation. If the decisions of the Guardians are to undergo revision, it is clear that time must be consumed in the process, and delay is therefore inevitable. In the meantime what are the Surgeons and their patients to do? Until the Dispensary is finally declared by the formal order of the Commissioners no medical relief can be administered out of the poor-rate, and unless the usual presentments for existing Dispensaries be granted by Grand Juries, no money can be obtained from the county. The Grand Juries must sooner or later defray the expenses already incurred, but they will probably avail themselves of the defect which the dropping off of subscribers has caused, and repudiate payment for the present. The truth is, that provision should have been made in the act to maintain the old Dispensaries up to the spring assizes of this year. If any doubt existed as to the obligation of the Grand Juries to defray all the expenses of medical relief, Surgeons'

salaries of course included, up to the date of the declaration of District Dispensaries by the Commissioners, it should have been removed; and if any doubt now exists on the subject, a short act should be passed to settle the matter. In order to expedite the arrangements now in progress, the Dispensary Surgeons should, in our opinion, refrain (as far as in prudence they can) from pressing questions of secondary importance, and for the present rest satisfied with what they can achieve in the way of instalment; under protest, if necessary, but at all events securing a safe position. In certain cases it may be absolutely necessary to resist unjust or partial proceedings, but it may be worth considering whether this may not be more safely effected hereafter. The Surgeons of the expiring Dispensaries who have not already taken steps to obtain presentments from the Grand Juries to defray the expenses of their institutions up to the date of their settlement on the poor-rate, should lose no time in doing so now, if not too late. What these steps should be we cannot tell, neither can we take the responsibility of advising as to the course to be pursued beyond a repetition of a hint lately given touching the necessity of union and organization. There must be concert, and there must be a central executive with funds, not necessarily very large, to secure vested rights, and remuneration for past services. A Committee should meet in every assize town during the spring circuits to consult and instruct counsel, and to have the necessary applications made to the judges. In fact, a Provincial Association must be formed for despatch of business and nothing else, leaving the expression of opinion on medical subjects in general to other arrangements and occasions. To Dublin they need not look for aid, for although there may be a few there anxious to coöperate with them, there are many prepared to obstruct or defeat any measure emanating from parties not belonging to a certain *clique*. Our readers will recollect how we warned them a few years ago against the cajolery of certain worthies who made the "five-shilling grievance" a contrivance to ride into their good graces, and who so pathetically told how heroically doctors died. Events past and present prove how correctly we judged on that occasion, and how necessary it is for us now to repeat our warnings. If the Surgeons of Ireland have not been sold, or are not in course of being sold, they may be satisfied; honest, hearty aid they need not expect from the quarter to which we point. For ourselves we have a word to say: some of our friends, very naturally disappointed with the turn affairs have taken, with great simplicity, assume that we have been prime movers in this matter, but the readers of the Press can tell them whether or not we were so. On the contrary, we incurred something approaching to odium for our cautious reserve as to the policy of the change, until it became inevitable. Then we set our shoulders to the work of promoting its salutary operation, and so we will continue, and not without hope of a successful result. Then some also would fain lay their own short-comings at our door, and make us answerable for their procrastination, apathy, and inattention, but have we not unceasingly directed attention to the matter until our subscribers not personally interested in the matter begin to grumble. The following observations in our number of September the 10th, nearly five months ago, prove that we were not asleep:—

Pending the decision of this affair, which so nearly concerns our brethren in the provinces, it may be prudent to look closely to local influences and resources, to inquire respecting guardians, *ex officio* and elected, large ratepayers and dispensary committee men in prospect. The geography of electoral divisions should also be studied, and the place of existing dispensaries therein ascertained, with the nature and amount of the population, and all other particulars necessary to enable a man to take part in the operations of the ensuing campaign. It is not when officials are in the field and new arrangements completed, that men are to commence inquiries as to the safest course to pursue for the preservation of their rights; it is before the plans of others become matured, and decisions are adopted by supreme authorities, that vested interests can be secured. We can assure our friends that the time for action has arrived, and that whoever fails to avail himself of the opportunity may find it difficult to meet another.

The following letter, affording appropriate illustration of our remarks, we append here:—

Waterford, January 22, 1852.

Sir,—I have the honour to present to you a statement of the dispensaries of this union prior to the passing of the Medical Charities' Act—viz.:

	Salary.	Vaccination.
1. The Kilmacow Dispensary	£100 ...	£12
2. The Dunmore Dispensary	100 ...	8
3. The Tramore Dispensary	100 ...	8
4. The Glanmore Dispensary	100 ...	6
5. The Waterford Dispensary	94 10s.	—

Making £528 10s., exclusive of occasional gratuities.

The dispensaries, as arranged by the board of the Waterford union, are—Waterford, £100; Kilmacow and Ullid, £80; Glanmore and Kilmacevogue, £80; Dunmore, £80; Tramore, £80. Total £420.

Under the former arrangements the dispensary districts were much smaller, several tracts of country being without dispensary relief. By the present arrangement the entire union is included, so that the duties of the dispensary surgeons will be much increased, and with one exception their salaries much diminished, and this at a time when, from the general distress of the country, they have but little prospect of support from private practice. It has been said in this boardroom: "Let the dispensary surgeons live by farming!" The medical man who devotes himself to farming, or any other occupation but his profession, will not be likely to discharge his dispensary duties with credit to himself; the medical profession is all engrossing. Like Aaron's rod, it swallows up everything, if efficiently discharged. It is the duty of the guardians to have the sick poor faithfully and efficiently looked after, and no inspection can secure this without securing the zealous coöperation of your dispensary medical attendants. And the surgeons of the dispensaries in this union feel that the board, by increasing to a large amount their professional duties, and materially lowering their remuneration, has not treated them with that consideration that they hoped, and still hope, will be extended to them. I beg also to observe to you that, with the exception of the Waterford Dispensary (to which you gave on the last board day a small supply of medicines), the other dispensaries of the union are without medicines, and the surgeons are without remuneration for their arduous professional services; and as might be expected, the patients in your fever hospital are on the increase. It will be necessary, should the board not enter into resolutions to enable the Poor-law Commissioners to send down, without delay, the sealed order for the opening of the dispensary districts of the union, that a medical inspector should be sent down to prevent the districts from being allowed to remain in their present unprovided state.—I have the honour to be, sir, &c., T. L. Mackesy, M.D.

To the Chairman, Waterford Poor-law Union.

The board unanimously agreed that the foregoing explanatory, rational, and humane letter be entered on the minutes.

MULTIPLICATION OF MEDICAL COLLEGES.

New Colleges start up as thick as blackberries, and old Colleges only think of how they can increase and multiply. In 1844 the Secretary of State introduced a bill into parliament to reduce the number of the seventeen doctor-manufactories within reasonable bounds; in 1852 nothing is thought of but their enlargement. Our provincial brethren may well look forward to the consequences with alarm. Here is a Birmingham College, and the University of Durham has erected another at Newcastle:—

Queen's College, Birmingham.—We have the gratification to announce that the royal assent has been given to

the supplemental charter of the Queen's College in this town, and the great seal attached to it. Amongst other privileges conferred on the town and midland district by this act of royal favour, the supplemental charter enacts, in order to promote the mining and manufacturing interests, "that students who have completed not less than a three years' course of instruction in the engineering and architectural departments of the said college, and have passed, to the satisfaction of the examiner or examiners to be appointed by the council of the said college, three public examinations, shall be entitled to the academic rank of Civil Engineer in the said college, and receive from the principal a diploma under the seal of the college." "Her Majesty's further will and pleasure is, that two members of the Institution of Mechanical Engineers and two members of the Architectural Society established in Birmingham, to be elected by their respective societies previously to the annual general meeting of the governors of the said college, shall be members of the council of the said college." It is also "her Majesty's further will and pleasure (in order to carry forward the statutes 6 and 7 Vict., c. 73, sec. 7, enacted to improve the education of students intended for the profession of the law) that two members of the Law Society established in Birmingham, to be elected by the said society previously to the annual general meeting of the governors of the said college shall be members of the council of the said college." Her Majesty has likewise been graciously pleased to nominate a committee of council of the theological department—namely, the Principal, the Vice-Principal, the Warden, the Treasurer, the Dean of the Faculty, the Lord Bishop of the Diocese, the Dean of the Cathedral of Worcester, the Archdeacon of the Archdeaconry of Coventry, the Rector of the Parish of St. Martin, and the Rector of the Parish of St. Philip, with important privileges and powers to act in such manner as shall appear to them best calculated to promote the purposes intended by the said department. By her Majesty's warrant, dated July 27, 1846, the principal and council were empowered to grant certificates for the admission of their students, *without any residence elsewhere*, to be candidates for the degrees of Bachelor of Arts, Master of Arts, Bachelor of Laws, or Doctor of Laws, to be conferred by the University of London; and previously the college was empowered to send its students for examination for the degrees of Bachelor of Medicine and Doctor of Medicine to be conferred by the same university, and also for the diplomas of the Colleges of Surgeons of Edinburgh and London, and the licence of the Society of Apothecaries, without any residence elsewhere. We have not space to enter into further details, but we cannot do otherwise than congratulate our townsmen, the patrons of the college, and especially the founder, Sands Cox, after twenty-five years of unexampled devotion, on the completion of the above combined system of education worthy this great midland metropolis.—*Aris's Gaz.*

TO CORRESPONDENTS.

We lately, in reply to a correspondent, stated that the decision in the case of the Apothecaries' Company against Nicholls, which settled the question as to the right of surgeons to compound and dispense medicines in Hospitals and Dispensaries, was to be found in a former number of the Press. It may perhaps be best for the information of those unable to refer to it to republish it. As soon as the new Dispensaries are finally declared, we will publish a list of them. The doings of the Guardians of the Killarney Union can be effectually restrained by the Commissioners only.

CORRESPONDENCE.

TO THE EDITOR OF THE MEDICAL PRESS.

Dear Sir,—Having been connected and intimately acquainted with the working of dispensaries for twenty years, may I beg to offer a few suggestions at the present (to the profession) most momentous crisis; and I am thoroughly convinced if such, or similar regulations are not firmly carried out by the commissioners, that its degradation will be complete. I dare say by this, you have come to the conclusion that I long since have, that the guardians collectively, as a general rule, have only one object—the lowest possible amount of taxation; the "doctors" and sick poor being matters of, I will not say, secondary consideration, but literally of no consideration whatsoever. Of course, there are a few honourable exceptions—"Apparent rari nantes in gusgite vasto," but sufficient to prove the rule. You have said the salary should be £100 per annum. Can there be two opinions on the subject among educated and uninterested men? When you take into consideration the onerousness and responsibility, the fatigue and anxiety of the duties to be performed, the risk and danger, which a reference to the mortality of dispensary surgeons will at once show; the cost and labour of acquiring the profession; and above all, the fact that the moment a man from age or illness is unable to work, his pay ceases. When we consider all this, the notion of offering the surgeon a paltry pittance of £60 or £70 is too absurd. This, I submit, is the proper ground to take, not the mere circumstance of his being obliged to keep a horse, &c. As for a man being indemnified by his private practice, I can tell you anything he gets in that way he is wonderfully well worked for.

Let the dispensaries be open a couple of hours every morning, as at present. All tickets to be delivered within those hours, unless a case of sudden and urgent illness, and of which I would allow the medical man to be the judge; and if it should appear on investigation by the committee that an improper person had been recommended, I would make the gentleman pay for him that had recommended him. It would be very little satisfaction to the surgeon to have the name merely struck off from the relief list, after having had the benefit of his labour and skill.

Ordinary midwifery cases were never part of the duty of the dispensary surgeon, and I cannot but think that some of your correspondents in anticipating them now must have made a great mistake. I take it for granted, as heretofore, that the surgeon's business will only be with those requiring surgical assistance. Were it otherwise, and were the duties of a parish midwife to be now imposed upon the already well-worked doctor, I venture to say that not ten per cent. of the medical men of Ireland would stand such wear and tear for even half a dozen years, and that the mortality among them would be greater than ever it was in the times of "plague, pestilence, and famine."

I would also suggest, that for the efficient working of the act it would be well to have half a dozen supernumeraries at, say £120 per annum and their travelling expenses—something after the manner of diocesan curates, to take the place of any dispensary surgeon temporarily laid up by illness; and if this arrangement could be so far extended as to admit of a short and occasional leave of absence—say a fortnight every couple of years—I am sure it would be turned to the best advantage by the mass of the profession, by making themselves acquainted with the almost daily improvement of the age. At one of the Dublin hospitals, probably this will be called a one-sided letter; that I take very good care of the medical man. I reply, there is not the smallest doubt but that he will be made to do his duty with fidelity. Without taking into consideration the surveillance of the inspectors, there will not be a single managing committee in Ireland on which there will not be three or four members who, from one motive or another, questionable or otherwise we will now not stop to inquire, will not consider it their duty, or rather I should say their privilege, to see that the "doctor" does not eat the bread of idleness.

Do not fancy that the dispensary surgeons are alone interested in the liberal carrying out of this measure. The teachers of Dublin are just as much concerned in it; for I can tell you, it is the expectation of an immense number of the guardians to be able to substitute by degrees for the present respectable and well-educated surgeons, a mongrel set, holding an equally uncertain position in the profession and in society, who will be satisfied with the paltry pittance and insolent treatment that will be awarded to them—a set of men that will be let loose on society by the "cheap-and-nasty" system of the Queen's Colleges; and there is no doubt they will succeed if they get the latitude they expect under the new act.—I am, dear sir, &c., A Subscriber.

P.S.—It is surprising the avidity with which every opportunity is seized on of brow-beating the "doctor," by fellows that never subscribed a shilling under the old system.

NEW MEDICAL REFORM BILL.

As secretary to a committee of members of the Provincial Medical and Surgical Association, formed for the purpose of bringing forward a measure of medical reform, in accordance with the principles so long advocated by that body, I have prepared a draft bill, which I now submit, through your columns, to the consideration of the medical profession.

Your readers will perceive that the purport of the bill is to establish a medical council for each of the three kingdoms, who will be the governing bodies of the profession, and will

hold a triennial congress, for the purpose of preserving an unity in their educational system. In England, this council is to be nominated—in addition to the *ex officio* members supplied by the Universities—by the Royal Colleges of Physicians and Surgeons, and the Society of Apothecaries. The constitution of the council for Scotland and Ireland is purposely left undecided, in order that the opinion of the medical profession in those countries may be obtained as to the course which will be most in accordance with their wishes. But it is hoped that under any circumstances the measure may be one which will establish a common system for the whole of the united kingdom. These councils are each to appoint an examining board before whom every person who in future enters the medical profession will have to appear, and on obtaining the *testamur* of the board, the candidate will have a licence granted to him by the medical council, and will assume the title of a Licentiate in Medicine, Surgery, and Midwifery. Any one who chooses to do so may stop here, and may practise, on the title conferred by his licence; but if he wishes to be a physician or surgeon, he must go to the Colleges of Physicians or Surgeons, and obtain from them their diploma; the bill only contemplates establishing one common primary test for all who enter the profession, whatever grade they may afterwards wish to assume in it.

Each of the medical councils is also to appoint a registrar, who will register at a very trifling fee the names of all medical men now in practice. Those who in future wish to follow the profession will be registered on the granting of their licence; and both classes will have to take out an annual certificate, and pay for it a fee of £1, of which one half will go to the formation of a provident fund. Considering the advantages which the working of the bill would, as it is supposed, confer upon the profession, I do not think that this annual payment can be considered an exorbitant one. The projected measure also provides for the establishment of a proper curriculum of study, for the enforcing of penalties against unregistered practitioners, and for the erasure of the names of certain parties from the register. It is perhaps needful to observe, that the way in which the bill is drawn, implies that new charters would be granted to the Colleges of Physicians and Surgeons within a brief period; it would interfere very little, if at all, with the present privileges of those corporate bodies, since their diplomas would still alone confer the titles of Physician and Surgeon. Nor, on the other hand, ought the bill to be objected to by that class—I believe a small one—of medical practitioners who desire a third incorporation; for this measure does not in any way debar them from the prosecution of their scheme, and should it pass into law, it will still be open for them to obtain, if they can, the object of their wishes.

In conclusion, I will say that the draft bill now laid before the profession has been the subject of much labour, and of long and careful consideration. It is impossible that any measure can ever be framed to meet the exact wishes of all parties; but it is hoped that the present one is in accordance with the sentiments of the great majority of medical practitioners, and that it is free from some of the objections that have been urged against its predecessors. United support from the whole of the profession will carry it through parliament, and nothing else will. It therefore remains for the medical men of the united kingdom to decide whether they will embrace the present opportunity of placing their profession on a satisfactory footing; always remembering that the minor details of the bill are open for alteration, and that their criticism is invited upon them. Of the soundness of the general plan, I think no question can be entertained, and it would be easy to build on it, if necessary, the structure of subsequent legislation.—*Letter of Mr. G. W. Hastings, Barrister-at-Law in Lancet.*

At a meeting of the Council of the Provincial Medical and Surgical Association, held on the 17th day of June, 1851, a draft of a proposed bill, entitled "A Bill to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine," was submitted for approval by a committee composed of members of the Association, who have long given the subject their careful consideration. It was resolved, that the bill, so prepared, seems to carry out the principles of medical reform so long advocated by the association, and that it is therefore highly desirable that the same should be forwarded by the secretary to the branch associations; and that they should be requested to report to him their opinions on the various clauses composing the bill, with as little delay as possible."

MEDICAL TRIALS.

KENMARE QUARTER SESSIONS—JAN. 5, 1852.

J. McCarthy, Esq., M.D., v. John O'Reardon, Esq., Coroner; Dr. Maybury v. Same.

In these cases T. W. Murphy and F. H. Downing, Esqrs., solicitors, appeared for the plaintiff, and Joseph O'Riordan, Esq., and the defendant himself, appeared for the defence.

Mr. Downing stated that the first was an action brought by the plaintiff against the defendant or coroner. It appeared that the plaintiff was called upon by the defendant to attend an inquest and make a post-mortem examination in a case of some importance, when it was apprehended that some party was to be committed for trial at the ensuing assizes; the doctor travelled a distance of thirty miles to where the inquest was held in a remote part of Tuosist, and made a post-mortem examination, and the coroner gave an order on the board of superintendence of the Tralee jail for the sum of £2 2s., being the amount allowed by the act 9th and 10th Victoria, chap. 37. This the board thought fit to reduce to £1, which the plaintiff refused to accept, and as he could get no more from the board, he brought an action against the coroner, who called on him and when summoned was obliged to appear.

Mr. T. W. Murphy stated that he was employed by another gentleman, Dr. Maybury, who had a similar case, and indeed he had been on many occasions heretofore similarly treated by the board of superintendence, who in his (Mr. Murphy's) judgment assumed a power that they did not possess, and which was contrary to the opinion expressed by the judge of assize, before whom these matters were brought, that of reducing the coroner's orders when post-mortem examinations were held and considered to be necessary, from £2 2s., as allowed by the statute, to £1, and in some cases rejected them altogether. Such being the case, no option was left to his client but to sue the party who employed him, and therefore he hoped his worship would grant decrees for the full amount claimed, £2 2s. in each case. His clients travelled over twenty or thirty miles, and had a very unpleasant duty to perform, that of making a post-mortem examination on a body far in a state of decomposition, and it would be a monstrous thing that a medical gentleman travelling this distance and performing those duties, taken away from his other professional calls, should not get the amount claimed by the act.

Mr. O'Riordan, the coroner, admitted having called on those gentlemen, and that the distance was such as stated by their solicitors; but contended that it was never intended that he, or any other coroner, should be held personally liable to the medical gentlemen giving their attendance, and called the barrister's attention to the different sections of the act, 8th and 10th Victoria. chap. 37, secs. 28, 29, and 30, which regulated the mode of payment to medical and other witnesses, and stated that the practice was for the grand jury to present a certain sum to the board of superintendence for those purposes, that the coroner then gave orders on the board, considering that the clauses gave them an option to pay all, or such portions as they may think fit of those orders, who occasionally did so reduce them—that he or any of the coroners never called a doctor, except in cases where he considered it absolutely necessary, and that he regretted they should not be paid, as they, on most occasions, deserved. But again, he most respectfully submitted, that the doctors should bring the matter before the grand jury and judge of assize, and not look to him personally.

Mr. Murphy further stated that his client, Dr. Maybury, had, in consequence of the manner in which he was treated by the board of superintendence, determined not to attend any other inquest, unless the coroner gave a personal guarantee to pay him, and not refer him to any other quarter.

His Worship said that having looked at those different sections, and having fully considered them, he was of opinion that the 28th section authorises the coroner to pay the medical witnesses the sum mentioned in the schedule of the act, and he considered the fair construction of the act was, that the coroner had the discretion to give orders in accordance with the schedule, and it would be unwise not to give him the power, and it was the true intent and meaning of the section that the board of superintendence should pay accordingly. Section 30th bore out this view, which directed the grand jury to present such sum to the board of superintendence as they required to pay the coroner the amount of the orders pursuant to the sum mentioned in the schedule, and as he could not see that it left any discretion with the board, he thought they were bound to pay them. Suppose the coroner to hold an

inquest where the person comes by his death by unfair means, and that he could not get in the locality a properly qualified practitioner, and that one would not attend from a distance for fear of not being paid, the ends of justice would be frustrated by the delay; and when by another section of the act the coroner had power to impose fines on medical men for not attending, if summoned, it never could be contemplated that they were not to get the amount mentioned in the schedule, which could not exceed £2 2s. Having no doubt that he was putting the proper construction on the act, he should decree the coroner in each of these cases for £2 2s. He was of opinion that the board of superintendence could not refuse to reimburse him; that they were bound to do so by the act.

To Drs. McCarthy and Maybury the thanks of the Surgeons of Ireland are due, and are hereby given, for this practical assertion of their rights. Henceforth these attempts to deprive medical witnesses of their fees will be less frequent.

M. W. HANLON, M.B.

TESTIMONIAL TO DR. HYNES OF KINVARA.

At an Aggregate Meeting of the Subscribers of the New Quay and Ballyvaughan Dispensary, County of Clare, and of the Kinvara Dispensary, County of Galway, held in the Courthouse, Kinvara, on Friday, the 23rd instant,

Samuel Bindon, Esq., in the chair,

The Rev. F. Arthur, P.P., being requested to act as Secretary, the following resolutions were unanimously adopted:—

Resolved—That we, the Subscribers of the New Quay and Kinvara Dispensaries, being anxious to place on record our estimation of the professional abilities of Dr. D. J. Hynes, as Medical Officer of these Institutions, before their management is transferred, agreeably to the provisions of the Medical Charities' Act, to the Poor-law Commissioners, avail ourselves of this opportunity to give expression to our sense of the high esteem and respect in which he has been held by us during his long connexion (now thirteen years) with these charities, both as a humane public officer and a successful medical practitioner; and to express a hope that the sick poor of our several districts may still continue, as far as it may be deemed feasible, to enjoy the benefit of his kind attention and professional skill as heretofore.

Resolved—That with the view of carrying out the intention of this meeting fully, a committee be formed, consisting of the magistrates, clergymen, poor-law guardians, and others, residing in those districts, who shall collect subscriptions for the purpose of purchasing a suitable Testimonium, to be presented with an appropriate Address to Dr. Hynes, as a mark of our approbation of the manner in which he has discharged his onerous public duties, as well as a token of our sincere regard for himself personally.

Resolved—That a copy of these resolutions be forwarded to the Poor-law Commissioners by our Secretary.

Samuel Bindon, Chairman.
Francis Arthur, Secretary.

Kinvara, January 23, 1852.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By William Henry Porter, M.D.,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on Venereal Diseases, with additional Notes and Illustrations.

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, and CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *leitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT

AT

G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

Bleeding, Cupping, the Application of Leeches, &c.

G. O. and Co. continue to be supplied with the Foreign Mineral Waters Fresh from their various Springs.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

MR. CHURCHILL'S PUBLICATIONS.

The PRINCIPLES and PRACTICE of OBSTETRIC MEDICINE and SURGERY. Third Edition, with 120 Illustrations on Steel and Wood. 8vo, cloth, 22*s.*

By F. H. RAMSBOTHAM, M.D.,
Physician to the Royal Maternity Charity.

"This new edition of Dr. Ramsbotham's work forms one of the most complete and thoroughly useful treatises on midwifery with which we are acquainted. The entire work has undergone a careful revision, with additions. We have already given specimens of the work sufficient to justify our hearty recommendation of it as one of the best guides that the student or young practitioner can follow."—*British and Foreign Medical Review.*

MEMORIALS OF JAMES MACKNESS, M.D.

Foolscap 8vo, cloth, 4*s.* 6*d.*

"The whole course of Dr. Mackness's life is full of instruction. We shall be satisfied if we induce our professional brethren to peruse this interesting biography, and if they derive as much pleasure from it as we have done."—*Dublin Quarterly Journal.*

ON DISEASES OF THE SKIN.

Third Edition, 8vo, cloth, 12*s.*; or with Coloured Plates, 30*s.*

By ERASMUS WILSON, F.R.S.

"The work is very considerably improved in the present edition. Of the plates it is impossible to speak too highly. The representation of the various forms of cutaneous disease are singularly accurate, and the colouring exceeds almost nything we have met with in point of delicacy and finish."—*British and Foreign Medical Review.*

THE ANATOMIST'S VADE-MECUM; a System of Human Anatomy. Fifth Edition, foolscap 8vo, cloth, 12*s.* 6*d.*

By ERASMUS WILSON, F.R.S.

"We are glad to welcome a fifth edition of this *multum in parvo* of anatomical information. We think we may fairly say, that no manual of anatomy has ever before met with such a favourable reception as this. Whether we regard conciseness and clearness of description, accuracy of detail, or the admirable character of the illustrative wood-engravings, we know of no work better calculated to serve as a guide to the student at the dissecting-table. Even those venerable gentlemen who think that medical science is now ruined by small books, and who sigh for folios and quartos, must admit that this *Vade-mecum* is a better student's companion than the ponderous octavos of a quarter of a century since. In fact, a slight examination will show, that although its size is smaller by one-half, it contains, by reason of the small type employed, double the quantity of matter."—*Medical Gazette.*

On the PHYSIOLOGY and DISEASES of WOMEN, and on PRACTICAL MIDWIFERY. 8vo, cloth, 12*s.*

By JOHN ROBERTON, formerly Senior Surgeon to the Manchester and Salford Lying-in Hospital.

"We honestly recommend this work to our readers as one calculated to interest them in the highest degree."—*Provincial Medical and Surgical Journal.*

"We recommend this work very strongly to all engaged in obstetric practice, or interested in ethnological studies. It possesses practical utility and physiological interest, combined with the fruits of a large experience, great power of observation, and an extensive and varied erudition."—*Med. Gaz.*

"We trust that the strong opinion we have expressed of the value of this volume will induce our readers to study it carefully for themselves, and we can assure them that they will be amply repaid."—*Dublin Quarterly Journal.*

On DISEASES of the URINARY and GENERATIVE ORGANS (IN BOTH SEXES). Second Edition, 8vo, cloth, 20*s.*, or with coloured plates, 30*s.* Part I. Non-Specific Diseases. Part II. Syphilis.

By WM. ACTON, late Surgeon to the Islington Dispensary.

"Mr. Acton's work must be diligently studied by every practitioner who would desire to benefit instead of injuring his patient; it has a distinctive and preëminently diagnostic value."—*Medical Gazette.*

"The present edition of Mr. Acton's work is much enlarged, and contains a most valuable collection of matter."—*Lancet.*

"We have no doubt Mr. Acton's treatise will take its place among the standard treatises in medical literature—a position to which its merits so well entitle it."—*Dublin Medical Press.*

SURGICAL ANATOMY.

By JOSEPH MACLISE, F.R.C.S.

	£	*s.*	*d.*
Sets in Numbers	2	5	0
,, bound in cloth	2	10	0
,, half-bound, morocco	2	17	0

This great work being now complete, the publisher confidently presents it to the attention of the profession as worthy in every respect of their approbation and patronage. No complete work of the kind had been published in the English language, and it therefore supplies a want long felt, of an accurate and comprehensive Atlas of Surgical Anatomy, to which the student and practitioner can at all times refer, to ascertain the exact relative position of the various portions of the human frame towards each other and to the surface, as well as their abnormal deviations. The importance of such a work to the student, in the absence of anatomical material, and to the practitioner when about to operate, is evident; while the price of the book, notwithstanding the large size, beauty, and finish, of the numerous illustrations, is so low as to place it within the reach of every member of the profession.

MEDICINA MECHANICA; or the Theory and Practice of Active and Passive Exercises and Manipulations in the Cure of Chronic Disease. Post 8vo, cloth, 6*s.*

By JOHN W. F. BLUNDELL, M.D.

THE PRESCRIBER'S PHARMACOPŒIA; containing all the Medicines in the London Pharmacopœia, 1851, arranged in Classes, according to their Action, with their Composition and Doses. 4th Edition, 32mo, cloth, 2*s.* 6*d.*; roan tuck, 3*s.* 6*d.*

By A PRACTISING PHYSICIAN.

On the PHYSICAL DIAGNOSIS of the DISEASES of the LUNGS and HEART. Post 8vo, 7*s.*

By HERBERT DAVIES, M.D.,
Fellow of the Royal College of Physicians, and Senior Physician to the Royal Infirmary for Diseases of the Chest.

"A book well worthy of the closest study of the profession. The author has eminently succeeded in bringing under notice, within a small compass, all the most valuable facts which relate to the theory and practice of auscultation."—*Medical Gazette.*

"The best epitome of the doctrines of the German auscultators and others that we have yet met with in the English language."—*Monthly Journal of Medicine.*

"An excellent practical manual."—*Dublin Medical Press.*

SURGICAL SOCIETY OF IRELAND.—FEB. 7.

Dr. JACOB in the chair.

PERFORATION OF THE LARGE INTESTINE.

By JOLLIFFE TUFNELL, Esq., M.R.I.A.

MR. TUFNELL detailed a case of enteritis consequent upon the swallowing of a foreign body, terminating in peritonitis and death, from perforation of the large intestine. The subject of this history was a fine healthy man, aged 46. He was quite well upon the 16th of March, 1851, and partook heartily of a turkey for his dinner on this day. He remained free from any uneasiness in the alimentary canal until the 20th, when, after retiring to rest, he was seized with colicky pain in the abdomen, accompanied by slight nausea, but no vomiting. This increased during the night, and early the following morning I was sent for.

I found him walking up and down the room, complaining of griping pain in the region of the umbilicus, across which he frequently passed his hand, not pressing the epigastrium, but rubbing the cartilages of the ribs. His countenance was rather anxious, and he seemed to be suffering a good deal of distress. He said that he was sure something was disagreeing with him, but he could not tell what, as he had been living very plainly, and had eaten nothing unwholesome. His tongue was slightly furred; the bowels had not been moved for two days, and there was slight disposition to tenesmus.

I ordered him to take three grains of calomel and a grain of opium at once, followed four hours after by a full dose of castor oil. I recommended him to keep warmly covered in bed, and to have the belly well and frequently fomented. To take no solid food during the day, and to repeat the castor oil next morning if uneasiness of the abdomen remained, or the evacuations from the first dose were not full and satisfactory.

I visited him the following morning, and found matters had not improved. His appearance was more anxious, and he complained of increased pain in the abdomen, and that of a more continued character. There was general tenderness of the surface, and disinclination to allow the parts to be examined; the pulse was frequent and small, and other symptoms of enteritis present. I should mention that there had been no action from the bowels. The first dose of oil had been rejected from the stomach, and the second (which he had taken a short time before) was also thrown up, accompanied by the discharge of much yellow bile. Active treatment was now had recourse to. He was bled freely from the arm, and leeches applied over the most tender portion of the abdomen in the right hypochondriac region. Three grains of calomel and one of opium were ordered to be taken every third hour; continued fomentations to be applied to the belly, and enemata of tepid water thrown every six hours up the bowel. This treatment was steadily persevered in, and for a time seemed to give him relief. The bowels were fully and frequently moved, and he expressed himself as feeling much better, and he bore pressure over the abdomen sufficiently to allow of a belladonna poultice being applied.

This improvement, however, was of short duration. The succeeding day the belly was tympanitic, and the abdominal pain greatly increased, the pulse more frequent, and the debility greater; still he did not despond, or even manifest as much anxiety about his condition as before.

Throughout the 25th he declined in strength, whilst the peritonitic symptoms increased. On the 26th I visited him early, and found no change in his general condition, except that the stomach had become more irritable, and that he had vomited frequently in the night. The gums now showed evidences of the mercury having affected his system. The same treatment had been continued, excepting that he was now taking beef tea, chicken broth, and wine in small quantities, with Wenham Lake ice.

Shortly after quitting him, I was hurriedly sent for, and on arriving found a great and unexpected alteration in his condition. His features were shrunken and altered; his pulse not perceptible at the wrist; the belly immensely distended, and the surface of the body damp and cold. He had been talking to a friend shortly after my departure, and was in the act of conversing, when he sud-

denly exclaimed "*I am lost; something has burst;* I am dying!" and immediately his countenance fell. The sudden supervention of these symptoms, and the rapid sinking of the vital powers, indicating perforation of the intestine, I adopted, as a *dernier resort*, the opiate treatment. I gave him sixty drops of laudanum in a little brandy and water at once, and followed it up by a second dose of forty drops after the interval of an hour. He never, however, made any attempt to rally, and sunk five hours from the time when the intestine gave way.

Having obtained permission to examine the body, I did so, assisted by Dr. Carte, twenty-four hours after death. The abdomen was *enormously* distended, and on making a section of its walls, gas escaped in such quantity, and so offensive in character, as to oblige us to retreat quickly from the room. On returning, and viewing the cavity of the belly, we found the intestines lying agglutinated together, universally inflamed, thick, massy, and of a deep purple colour, attached to each other by yellowish matter, and lying in a considerable quantity of brownish serum, containing shreds of coagulable lymph. In the right iliac fossa appeared a quantity of thin bright yellow fæcal matter, proceeding out of a perforation of the large intestine, three inches above the caput coli, about the magnitude of a split pea. Through this opening was projecting a hard-pointed body; which on being drawn out, proved to be a portion of the pinion-feather of a turkey, measuring 6-8ths of an inch in length, and of the calibre of a No. 1 bougie, evidently derived from the bird off which the unfortunate man had dined shortly before. This, in its passage through the bowel, had got entangled in the crescentic folds of the mucous membrane of the colon, been closed on by the muscular fibres, driven into the lining of the intestine, there established enteritis, this being followed by peritonitis, ulceration, perforation of the bowel, and death.

Dr. Benson remarked, that although cases of enteritis and peritonitis from bodies lodged in the vermiform process were of somewhat frequent occurrence, he could not remember having met with any case like that which Mr. Tufnell had brought under their notice that evening. Many of the members then present might, however, recollect the case of a very interesting medical student who died five or six years ago from an attack of enteritis with peritoneal inflammation, the cause of which was not ascertained during the lifetime of the patient. The case was attended by the late Dr. Houston, by himself, and several other practitioners of Dublin; but though every means in their power were employed to arrest the progress of the inflammation, their efforts proved altogether abortive, and the patient ultimately sank under the disease: but after his death it was discovered that the cause of the inflammation was the seed of an orange which had been lodged in the vermiform process, and which had given rise to inflammation that subsequently extended to the peritoneum. Some years before this patient met his death, Dr. C. Johnson of Merrion-square, requested his assistance at a post-mortem examination of the body of a child who had died of enteritis and peritonitis; and on making a very careful search in that case, a solid body, larger than a pea, and composed of magnesia matted together by mucus, was found impacted in the vermiform appendix. It was plain, from an ulcer at the part, and the intensity of the inflammation just there, that this inflammation and the death of the patient were owing to the presence of this foreign body, and on making inquiry, it was ascertained that the child's mother was very much in the habit of administering *magnesia usta* to her children, and that she had given it frequently as an aperient to the child in question. He referred to these cases with a view of corroborating Mr. Tufnell's statement, as to the slight causes which occasionally led to the most fatal results. Such cases as Mr. Tufnell's must, however, be exceedingly rare, for he was not able to recollect having ever met with one of a precisely similar nature; cherry-stones and pippins were, he believed, frequently found in the vermiform process; but he was not aware of any other case in which a calculus of magnesia was discovered in that situation.

Dr. H. Kennedy stated that he had met with a case in which a calculus blocked up the vermiform process, caused an opening through it, and gave rise to symptoms like those in Mr. Tufnell's case. He had also met with cases where the same results were produced by the pippins of an apple and of an orange; but all these were confined to the vermiform process. Before sitting down, he wished to ask Mr. Tufnell whether he was of opinion that all the morbid changes were going on in his case before the perforation took place in the intestine? It was not usual perhaps for the inflammation to spread until the perforation had occurred; but Louis had recorded a considerable number of cases where three, five, seven, and even ten days had elapsed after the perforation before death ensued.

Mr. Tufnell replied that the inflammation was of a progressive kind in the case to which he had directed the attention of the Society; the lodgment of the stump of the feather in the mucous surface giving rise to enteritis, subsequently to peritonitis and death. For three days before death there was great tenderness, and the abdomen was in a tympanitic condition for forty-eight hours prior to the same event. The period which elapsed from the time when he cried out that *he was lost* to the moment of his death, could not have been more than four hours, and Mr. Tufnell dated the perforation of the intestine to this time only: viz., about four hours before decease. Dr. Benson had alluded to lodgments of foreign bodies in the vermiform appendix, and death consequent upon their presence. These cases, though generally fatal, were not universally so. Mr. Tufnell was aware of one instance where this had occurred, where protective inflammation had been set up, and the offending substance been safely discharged by suppuration. It happened in the practice of Dr. H. Irvine to a lady who swallowed a molar tooth, which remained in the intestine for thirty years. During this period Dr. Irvine had frequently treated her for colicky pains, and at length, about three years since, after a severe attack, abscess appeared in the right iliac region, on the opening of which the tooth protruded, and the patient recovered her original state of health. Mr. Tufnell might call attention, whilst speaking of impaction of substances in the bowels, to another case, where the foreign body was lodged lower down in the intestine. It was mentioned to him by the late Dr. Carline of the Carbineers, who was sent for in the middle of the night to attend an officer, suffering from extreme agony, referrible to the abdomen. Opiate enemata were administered, and Dr. Carline remained for a couple of hours with his patient, who was all that time groaning with pain. He next ordered tepid enemata, which affording no relief, he proceeded to make an examination of the rectum with his finger, where, about two inches above the anus, he found (the gentleman having partaken at dinner of mullagatawny soup) a portion of the bone of a fowl, the sharp ends of which were stuck in the mucous surface of the rectum, and retained there by the spasmodic contraction of the sphincter upon them.

Dr. Benson remarked that fish bones were frequently detained in the rectum in a similar manner.

Dr. Jacob observed that the only wonder was that such cases were not of more frequent occurrence, considering that foreign bodies of different kinds were swallowed by thousands of persons every day in the week. It was an established fact that, in the great majority of cases, such bodies passed away without interruption; and yet, in the present case, a very small fragment of a feather had passed the pylorus and the ileo-cæcal valve, and had not become entangled until it made its way into a cell of the colon.

CASE OF STRANGULATED INGUINAL HERNIA.

By Charles Trenerry, M.R.C.S.Eng.,
Assistant-Surgeon of Civil Hospital, Gibraltar.

(Communicated by Dr. Tyler.)

On May 7, 1849, Catalina Vicenté, aged 15, a handsome looking young woman, with black hair and large dark eyes, was admitted into the Civil Hospital, about eight p.m., suffering from inguinal hernia of the right side.

She was suddenly seized with pain in the stomach, about

twelve o'clock yesterday, whilst dressing for church, which caused her to have a stool; afterwards she vomited her breakfast and a quantity of green bilious fluid.

The vomiting continued nearly the whole afternoon, night, and following day, especially if she took any liquids. These symptoms did not excite any alarm till this evening, as she suffered somewhat in a similar manner, for the last twelve months, on the appearance of the catamenia.

She positively asserts that the swelling has been in the groin more than a year without once disappearing, and it invariably increased in size on each accession of the menses.

At present she is much agitated at being brought into hospital; there is tenderness of abdomen, and a small moveable swelling in the right groin. Warm poultice to be applied to abdomen; belladonna plaster to groin; a cathartic enema.

℞ Extract. opii gr. i. statim sumen.

8th. Passed a pretty good night; the swelling is lessened; bowels have not acted.

℞ Ol. ricini ʒiss. statim.

She rejected the oil almost immediately; an hour afterwards took ten grains of calomel, which she also vomited. To take half a grain of extract of opium every second hour: apply the taxis.

Two p.m. Tenderness at scrobiculus cordis much increased; swelling in groin larger, and she has occasional hiccup; bowels have not acted. Eight p.m. Constant vomiting and hiccup. To be placed in a warm bath and continue the taxis, which caused an evident diminution of the hernia. Three pints of cathartic mixture were injected and produced a slight loose feculent offensive stool. She is afraid to take anything, as it induces vomiting.

9th. Passed a very good night; had a slight but offensive stool this morning; complains of the tenderness of abdomen, but particularly so at the scrobiculus cordis. Ten a.m. Has had a copious loose greenish stool, attended with much griping. An enema was administered, which brought away a copious feculent stool. Hot chamomile fomentations afforded relief to the griping; has been able to retain some sago.

10th. Passed a pretty good night, and feels better this morning, but there is occasional hiccup and nausea.

11th. Passed a pretty good night, but still complains of the tenderness over the abdomen and across the hypogastrium; she is constantly moaning; bowels acted slightly during the night.

℞ Hydrarg. chlor. gr. x. statim.
Mercurial frictions to abdomen and hot poultices.

One p.m. Increased tenderness of abdomen, and an inclination to vomit. Apply three dozen leeches to abdomen, and administer an enema. The enema was evacuated without any stool or relief to her pains; abdomen somewhat distended, but she can bear tolerable firm pressure. Six p.m. *Suddenly vomited* a large quantity of *stercoraceous matter*, and became much exhausted.

℞ Extract. opii gr. i. statim.

12th. Passed a pretty good night, having taken tea and sago without vomiting, but has no relief from the pain at scrobiculus cordis. Eight p.m. Has been able to retain some broth, tea, and sago, also nine drachms and fifty-six grains of pure quicksilver, which was divided into two doses. Apply four dozen leeches to scrobiculus cordis.

℞ Extract. opii gr. i. h. s. s.

13th. Passed a good night, and is much revived this morning; felt an inclination to go to stool, and after much straining evacuated a thick, heavy whitish mass, something like masticated boiled fish. Seven p.m. Has vomited two chamber potfuls of *stercoraceous matter*: complains much of exhaustion, thirst, and occasional vertigo.

℞ Hydrarg. chlorid. gr. iij.
Ext. opii gr. i. tertia quaque hora.

Ten p.m. Abdomen tense and painful; occasional hiccup and inclination to vomit; altogether she is much distressed, and has been talking incoherently for some time. Omit the pills. To take effervescing draughts during the night, and keep hot poultices to abdomen.

15th. Symptoms considerably aggravated by constant hiccup; frequent vomiting of stercor; great tenderness of abdomen; tympanitis; thirst; anxiety of countenance and prostration of strength.

It was now agreed in consultation with Drs. Key, Mery, and Cortes, that the only prospect for her relief would be an operation, which I accordingly performed at six a.m. this day. The patient being placed under the influence of chloroform, the usual incisions were made through the skin, superficial fascia, tendon of external oblique, and two or three adventitious membranes, when the sac was brought into view in a highly vascular and thickened state, and strongly adherent to the surrounding structures, which prevented the reduction of the hernia by division of the stricture exterior to the sac; therefore I cautiously opened the sac, and exposed a knuckle of intestine in a tolerably healthy condition. The neck of the sac was then divided, but the intestine would not recede, notwithstanding all our manipulations, it appearing to be firmly adherent round the neck of the sac, but it became a little flaccid, so we deemed it advisable not to meddle with it any further. The wound was brought together with a suture and strips of adhesive plaster; she was placed in bed, and appeared to have suffered little by the operation.

Twelve noon. She has been dozing nearly all the morning; is very pale; respiration hurried; abdomen tense and painful. Four p.m. She feels much better; bowels have been rumbling since the operation, and she felt soon after twelve o'clock as if a weight had suddenly fallen from the scrobiculus cordis to the lower part of the abdomen, since which she has had frequent feelings of going to stool; she has been twice to the night-stool unobserved without effect. Eight p.m. Has taken broths and soda water several times during the day; has hiccup at long intervals; abdomen much distended, but less painful.

℞ Extract. opii gr. i. statim.
Catap. lini abdomini.

16th, six a.m. About one o'clock this morning had two copious peasoup-looking evacuations, nearly filling the night-stool; is much relieved in every respect. Nine a.m. Has had two more copious evacuations of the same character as the last. Two p.m. Has had another copious evacuation; complains of giddiness whenever she sits up; an erythematous rash suddenly appeared over the body, and particularly the extremities; has much thirst. To drink lemonade. Seven p.m. Has had another very copious evacuation, making altogether about six potfuls.

℞ Mist. cretæ comp. c. tr. catechu omni hora.

20th. Is much improved; bowels acted twice; stools of good consistence and healthy looking; her aunt collected from the last stool a number of globules of mercury, some quite black, and others in a pure state.

21st. Wound granulating fast; the *hernia has receded spontaneously*; has had another evacuation, and with it voided more quicksilver in its natural state: we collected 284 grains. To our surprise she states that she *voided a musket bullet* last evening, which she had been induced to swallow on the 11th instant by her godmother, who assured her a man of her acquaintance swallowed six bullets, and was cured of a similar disease; the bullets were voided twelve days afterwards.

June 3rd. Was discharged quite well, and about three weeks afterwards had a truss adjusted, as the hernia protruded occasionally.

Observations.—The points of peculiar interest connected with this case are: In the first place, the hernia having existed for twelve months without disappearing, and at each menstrual period increasing in size, attended with sickness and colicky pains. 2ndly. The hernia could not be reduced even before or after the operation. The bowels were not altogether obstructed, as she had a stool on the 8th, 9th, and 11th; but notwithstanding, there was great tenderness at scrobiculus cordis, hiccup, and vomiting, which led us to suspect gastritis; but on the other hand, the suddenness of the attack and existence of the hernia almost precluded such a supposition: however, the indication was

to allay the irritability of the stomach and restore the proper peristaltic action of the intestines, and watch for more urgent or decided symptoms of strangulation. On the evening of the 11th, stercoraceous vomiting occurred, probably induced by the bullet. On the 12th, at the urgent solicitation of her friends, we gave her the quicksilver—a portion of which, I suspect, was voided the following day in the form of a heavy whitish mass—an albuminate of mercury, or the mercury in combination with the mucus of the intestines. The substance was accidentally thrown away, so that we had not an opportunity of examining it minutely. On the 15th, there was an aggravation of symptoms that decided us upon performing the operation. On exposing the knuckle of intestine it was found to be in a tolerably healthy condition, but resisted all our manipulations at reduction, as it appeared to us from adhesions at the neck of the sac; yet on the 21st it was found that the hernia had receded spontaneously.

Now, what could have resisted our efforts at reduction? Could it have been the superincumbent weight of lead, quicksilver, and feculent matter pressing down the intestine and opposing a greater amount of resistance than we could consistently overcome? or were the adhesions removed by the peristaltic action of the intestine, aided by the great amount of matter that was evacuated? The quicksilver was not voided till eight or nine days after being taken, and the *bullet* had been retained for a like period.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

WARM DEBATE ON THE SPECULUM.

It having been announced that Mr. Pollock's paper would be read this evening, the meeting-room was unusually full. On taking the chair, the President said that on this evening it was his duty to nominate the auditors of the Society's accounts for the past year. Having named several gentlemen to fill this office, the following paper was read:—

AN ABSTRACT OF FIVE HUNDRED AND EIGHTY-THREE POST-MORTEM EXAMINATIONS OF THE UTERINE ORGANS, MADE AT ST. GEORGE'S HOSPITAL FROM 1841 TO 1850; ILLUSTRATING THE PATHOLOGY OF THE UTERUS, FALLOPIAN TUBES, OVARIES, BROAD LIGAMENTS, AND VAGINA.

By George Pollock,
Late Curator of the Museum, and Lecturer on Anatomy at St. George's Hospital.

The records of the "statistics" of disease, founded on accurately recorded post-mortem examinations, especially of the uterine system, is a branch of medical literature which, perhaps, of all others, has been much neglected; and the author had not met with any work in which such a record as the following, of post-mortem examinations of the uterine organs, can be found. The bodies of 583 women were examined in a period extending over ten years; and out of this number, 265 cases were found affected with disease in some form or another.

Fibrous Tumours.—Out of 265 cases, thirty-nine were affected by the deposit or growth of fibrous tumours in the uterus. In thirty-eight of these cases the tumours were connected with the walls of the body of the uterus, either imbedded within them, or pendulous therefrom. In the thirty-ninth case, the tumour was attached to the cervix. In twenty-one cases, the tumours were single; but in one of these instances, in which the tumour was small, and in the upper part of the body, the os was much enlarged, and in structure resembled that of the tumour. In six of the twenty-one cases, the tumours projected into the cavity of the uterus, one very large, without a pedicle, and three were pendulous; one of which latter had so distended the uterus and vagina, that death followed sloughing of the vagina, urethra, and neck of the bladder. In eighteen cases the tumours were double or more numerous, and in five of these some of the tumours projected into the cavity. In two of these cases the tumours had escaped into the vagina, and were much ulcerated on their surfaces. In one case a calcareous covering surrounded the tumour, and the same process of generation was observed in its interior. In one case, two tumours projected into the cavity of the peritoneum, and, connected with the uterus by thin, long pedicles, they readily moved in the abdominal cavity. In a second case, a large tumour attached to the anterior wall projected into and filled the pelvis. In two cases ligature had been applied to the pedicles of tumours. In one case the patient died *before* the separation of the tumour; in this case there was a second tumour: in the other case there was no second tumour; the patient died of peritonitis *after* the separation of the tumour. The age of the youngest person in whom fibrous tumour was found was twenty-six; and this was the only case under thirty. Several were between thirty and forty; the oldest was sixty-eight. Taking the 583 cases as the guide, the average of women affected by this disease is nearly seven per cent.

Cancer.—Cancer of the uterus existed in thirty-eight cases, not, however, confined to the uterus alone, but implicating, in many instances, the adjoining parts. In twelve of these cases, "cancer" of some other viscera (not including the organs of generation) was present; and in four of these cases the breast was affected. In twenty-three of these cases, more or less ulceration existed; and in nine of them, some communication had been formed, either between the uterus, bladder, vagina, and rectum. In one case, ulceration had occurred into the cavity of the peritoneum; and in a second case, the peritoneum between the bladder and rectum was nearly perforated. When cancer exists in the uterine organs, with ulceration, sudden collapse coming on, followed rapidly by death, may thus be accounted for and anticipated, especially when the disease is confined to the upper portion of the uterus. A lady was suddenly seized with pain of severe character in the region of the left groin; this continued unabated, and independent of all remedies. About the end of two months, it suddenly subsided, after the discharge of pus from the vagina, but shortly recurred, and continued unrelieved. Within four months of the first symptoms, she died; and only within two days of her death did alarming symptoms appear; these were chiefly of great depression. After death, a small encephaloid tumour was found in the upper part of the uterus, softened in its interior, discharging very slightly into the uterus; but the peritoneal covering was just perforated, and allowed the suppuration from the tumour to escape into the abdomen. In fifteen cases, the cancerous matter existed as tumour, without ulceration. Six of these presented all the characteristics of scirrhus; in each case there was generally more than one deposit or tumour. In one case the scirrhous deposit was infiltrated among and in the pelvic viscera. In one case, there were simply small scirrhous tubercles of the vagina in the submucous tissue; but there also existed, in this case, encephaloid disease of the liver. In six out of the fifteen cases, the form of deposit was encephaloid. Four cases were affected with encephaloid tubercles in the walls of the uterus; and in one the encephaloid matter was infiltrated in the substance of the uterus. In one case, the deposit was of the celloid variety. The youngest person in whom cancer of the uterus was found, was twenty-three years of age; she was also affected with cancer of the breast. A second case was twenty-seven. The oldest was sixty-two years old.

Results of Pregnancy and Abortion were observed in nineteen cases. In most of the cases of abortion the uterus was larger than usual, in some being the size of the head of a full grown fœtus. The muscular structure, in several cases, was found much softened, flaccid, and readily lacerated; the mucous membrane often dull-coloured, congested, and even in one case gangrenous. In most cases there were traces of the adherent part of the placenta to be observed, and a shreddy appearance of the inner surface of the part corresponding to this position. In two cases abortion followed operations for strangulated hernia; in two cases erysipelas appeared the immediate exciting cause; in one case the complication of epilepsy existed; the abortion was most probably owing to diseased placenta,

the latter being in the condition commonly known as hydatid placenta. In one case an encephaloid tumour appeared to be the urgent cause of abortion. In one case of cancer the fœtus had apparently been dead for some time, but was retained. In one case syphilis was the apparent cause of abortion; five cases were attacked by peritonitis, subsequent to abortion, and death ensued; four were fatal from phlebitis. In one, retroversion following delivery, the uterus became so wedged in between the rectum and bladder that retention of urine, most extensive dilatation and inflammation of the bladder, and subsequently sloughing of the whole urethra and surrounding cellular tissue, took place and produced death.

Alterations in Structure of the uterus were observed in twelve cases—alterations which were of a doubtful character; that is to say with some suspicions of cancer, or dependent on external mischief. Three cases gave evidence of induration of the substance of the uterus, one being extremely hard, not enlarged, in a person sixty-four years old. One in the body and neck was so hard, that it was cut with great difficulty; this was in a person aged twenty-five. One in which the posterior lip only was remarkably hard. In one case the body was much enlarged, the neck elongated, and structure indurated; the neck and lips were extensively ulcerated and flocculent in a person twenty six years of age. In one case the cervix was remarkably hard, and of a dense white fibrous structure; this patient also had encephaloid disease of the breast. In these cases, the structure of the uterus was found softened: one in a case of dropsy; another after peritonitis following removal of an ovarian cyst. In one case, obliteration of the greater part of the cavity had occurred in a person thirty-seven years of age. The uterus was partly destroyed in one case by an abscess in the pelvis, and in another much congestion of the interior of the uterus attended an abscess in the neighbourhood.

Alterations of Form, Size, or Position of the Uterus occurred in twenty-nine cases. In three, position was altered: one was elongated, and drawn towards a hernial sac; one was anteverted; and one displaced by an ovarian tumour. In sixteen some enlargement occurred: one in the case of a girl, seventeen years old, affected by chorea; one in a case of menorrhagia. In a case of phthisis, the cervix was thickened and neck elongated. The uterus was found enlarged in one case of diseased heart; in a case of scarlet fever; in one case of dropsy; one in a case of pneumonia; two in phthisis; two in fever; three were of twice their natural size; in one case the uterus was drawn upwards by a tumour, and its cavity thereby dilated. In eight cases the uterus was smaller than usual, most of them being under twenty years; one case occurred in a woman aged sixty-four, a condition of atrophy not very rare in advanced life; in two cases extensive prolapsus had occurred.

An unusual condition of the Cavity of the Uterus, without actual Disease, occurred in six cases. Bloody fluid existed in the cavity in four cases, apparently menstrual. It has often occurred to me to examine the bodies of women reported to have commenced menstruating a day or two before death, yet no evidence of the local secretion or symptom of its presence were observed. In two cases coagula were found in the cavity—one in a case of cholera—one in a case of kidney disease.

Congestion of the Uterus was observed in twenty-one cases. This apparently depended on, or coexisted with, some general constitutional disturbance. The condition itself was not attended with alteration of structure, nor indication of incipient disease. In four cases, death was caused by fever; in three cases, by peritonitis; in one, it was attended with chorea; in one, by mania. In five, some disease of the brain existed; in one, disease of the heart; in one case, there existed phlebitis; in three, pleuritis; in one, rheumatism; and in one case, pleuritis, with general congestion of all viscera. In all the cases, there was some constitutional disturbance.

The Mucous Membrane of the Uterus, Cervix and Os, and the Vagina, was observed to be diseased or altered in its condition in twenty-three cases. In fourteen, some ulceration, or an appearance resembling ulceration, of the mucous membrane, was observed. Two occurred in patients with diseased hearts; in one, the mucous membrane of the vagina was highly congested and ulcerated near the os; in the other case, the os uteri was rough and congested, the membrane very superficially ulcerated; if "ulceration" can be the term applied to this condition of the mucous membrane. Two cases accompanied disease of the kidneys: in one, the membrane of the vagina and os was congested, and on the side of vagina and os were several aphthous ulcers; in the second, the membrane of the vagina and os was grayish and thickened, and covered with purulent secretion; on the posterior lip were two small ulcers. In a case of chronic peritonitis, the os was congested and superficially ulcerated; in the interior of the upper part of the body of the uterus, a small spot of ulceration existed in the mucous membrane. In a case of rheumatic fever, in the cavity of the uterus, there was a small ulcerated spot. One small superficial ulcer of the os occurred in a case of pneumonia. Two instances of superficial abrasion and minute ulcers of the os occurred in fatal cases of "fever." In two cases of diseased liver, there was abrasion of the mucous membrane round the os in one; in the other, the os was congested, and superficially ulcerated. In a case of phthisis, the follicles of the os were inflamed and ulcerated. In one case, superficial abrasion of the posterior lip, with two cicatrices of the posterior wall of the vagina, was accompanied by abscess of the pelvis. In one case, extensive ulceration of the side of the vagina, communicating with diseased bone. In nine cases, the alteration was not attended with ulceration. In one case, the mucous membrane was pulpy, after erysipelas. In three cases, it was vascular about the os, one being in a case of diseased heart, one in phthisis, and one in inflammation of the brain. In a case of diseased heart, the mucous membrane of the uterus was congested, and blood effused underneath it at the os; in another case, the membrane was covered with pus, and the sub-mucous glands enlarged; gonorrhœa was the supposed cause of the inflammation of the parts. In a case of diseased heart, the mucous membrane was covered with a white reticulated secretion. In one case, it was thickened, congested, and formed a flat vascular prominence, in a woman eighty years old. In one case, several little pendulous mucous tumours hung from the inner surface of the neck.

Scrofula of the Uterus existed in five cases. In a girl at sixteen, the cavity was filled with scrofulous matter, and the lining membrane entirely destroyed; the Fallopian tubes were also distended with the same secretion; the deposit did not extend beyond the os. There were also scrofulous tubercles in the brain and lungs. The second case was associated with phthisis. The inner surface of the uterus and Fallopian tubes were ulcerated, and their cavities filled with scrofulous deposit. The third case of a girl, aged eighteen, had extensive deposit in the uterus and tubes; the ovaries also had deposits of scrofulous matter in them, and there was general scrofula. The fourth case occurred in a person aged thirty-nine, was of a similar nature as regards the uterus, and was attendant on phthisis. The fifth case had the deposit round the body of the uterus, not in its cavity or substance; it was also accompanied with phthisis.

Mucous Polypus was found in one case, connected to the posterior wall about half an inch within the os.

Imperforate Vagina occurred in one case. The occlusion depended on the obliteration of about an inch and a half of the vagina. The case was operated on, and died soon after the operation and evacuation of the contained fluid.

Extra-uterine Fœtation had occurred in one instance; death followed rupture of the Fallopian tube, in which the fœtus and placenta had been contained. The tube burst into the peritoneal cavity, and extensive hæmorrhage followed. The fœtus was found in the cavity of the peritoneum.

Fistula between the Vagina and Rectum was seen in one case affected with phthisis.

Tumour of the Urethra occurred in one case. It was about the size of a hazel nut, of a dark venous colour, apparently not cancerous, and sprung from the inner surface, close to the orifice.

The Fallopian Tubes and Broad Ligaments were affected in thirteen cases. In two instances they were bound down by adhesions. In one case a simple fatty tumour was found in the tissue of the broad ligament. In four cases, simple serous cysts were connected with the broad ligament. The subjects, in three of these, were under twenty-one years of age. In one case, the extremity of the Fallopian tube was filled with pus; in another, a cyst, with pus, was situated in the cellular tissue of the tube. The Fallopian tube was obliterated at the inner extremity in one case, and at its other extremity dilated into a cyst filled with inky fluid. In another case, the extremity was dilated, and contained dark fluid; but the tube was pervious.

Tumours of the Ovaries, not Cancerous, were found in four cases. One case had a cartilaginous tumour in both ovaries. In one ovary a fibrous tumour was found, the uterus being at the same time similarly affected. In two instances calcareous masses were deposited in the ovaries.

Cancer of the Ovaries existed in eighteen instances; six were of the encephaloid variety, and solid in structure; eight were encephaloid combined with cysts. In four cases the ovaries were the seat of scirrhus. Out of eighteen cases, four were affected with cancer of the breast; in four the uterus was also affected; and in one case there was a cancerous tumour of the abdomen. In nine cases the ovaries were alone the seat of cancer. The age of the youngest affected was twenty-two; the age of the oldest, sixty-three.

Cysts of the Ovaries occurred in fifty-one instances. In thirty of these, the cysts were of the simple serous kind; in fourteen there existed but a single cyst; in sixteen there were more than one. In seven cases the cysts were complicated with abscess; out of these, in one, there was a clear cyst of the left, and pus in a cyst of the right ovary (after ligature of a uterine polypus). In one the abscesses are multilocular, and on one side opened into the rectum. In one a large cyst filled with pus occurred after phlebitis; in another, pus in a cyst attended cancerous ulceration of the uterus. In one case cysts occurred on both sides, some clear, others filled with blood, and one contained pus (after ligature of uterine polypus). In one case a cyst of pus and putrid lymph was complicated with fibrous tumour of the uterus. In one case both ovaria contained cysts with pus, apparently scrofulous, in a case of phthisis. In three cases "congenital cysts" were found; their contents were fatty matter, hair, and spiculæ of bone. In five cases cysts of the ovaries contained blood; two of these cases occurred in young women who suffered from chorea. In a multilocular cyst of the ovary, cholesterine mixed with thick tenacious fluid was found. In one case a large cyst had been removed during life; the patient did not recover from the effects of the operation. In five cases the cysts were complicated with solid matter. In one the ovaries converted into cysts had solid growths springing from their interior; the cysts communicated by a sinus to the rectum and bladder; this in a girl sixteen years old. The left ovary was affected by a compound cyst, with a large proportion of solid matter, in one case, while the right was affected with a simple serous cyst. In another case the left ovary contained a large clear cyst; the right was converted into one with thick cartilaginous walls, containing calcareous matter. In one case the right ovary presented an enormous mass, partly solid, partly cystic. In one the ovary was converted into a large cyst with growths within, one of the latter being filled with pus.

Scrofula of the Ovaries was found in four instances. In one both ovaries were greatly enlarged and filled with scrofulous matter and pus; there was also scrofulous disease of the peritoneum. In the second case both ovaries were filled with scrofulous matter; there was also phthisis. In the third the right ovary was a large thick cyst, containing scrofulous matter; the left, smaller, was similarly affected, and there was also tubercular deposit in the lungs. In the fourth case scrofulous matter was deposited in both ovaries, and there were other and general scrofulous deposits. The youngest person affected with scrofulous deposit in the ovaries was eighteen; the oldest, twenty-three.

Congestion of the Ovaries was seen in seventeen cases. Three of these occurred in cases of fever; one in a case of chorea in a girl fifteen years of age. In two cases the veins were varicose, dilated, and congested. In two cases, extravasation of blood was observed. A clot of recently extravasated blood was found in the ovary of a woman aged fifty; and spots of extravasation speckled the surface of the ovaries in a woman of forty.

Adhesions of the Ovaries were observed in thirteen cases: in two, apparently from proximity of cancer; in one, from numerous vesicles in each. The youngest case in which adhesions were found (exclusively of those associated with cancer) was twenty-five; and in eighteen instances the respective ages were under forty. The influence of this condition of parts in the production of sterility, with many other conditions already mentioned, should indicate precaution in the use of instruments, advocated by some practitioners, to overcome the mechanical obstructions which interfere with impregnation.

Displacement of the Ovary was observed in one case; it was adherent to a hernial sac; it was observed in the sac during life, at the time of the operation for the hernia.

Atrophy of the Ovaries was observed in ten cases. In one case, twenty-eight years of age, very little trace of the ovaries was found, in connexion with a pelvic abscess. In one case, they were absorbed by the presence of a tumour. In one case of forty-nine years old, and in another of eighty, they were observed atrophied.

In concluding this statement of the pathological conditions of the uterine organs, the author expresses the hope that the cases have not been collected together for no useful pathological or practical end. Independent of all theory, and irrespective of any speculations, relative to the functions of these organs, to the causes of their maladies, or to the plentiful remedies proposed or adopted in these maladies, when they are supposed to exist, these cases have been examined, recorded, collected, and are now given to the public. This method of collecting, recording, and comparing cases, can only ultimately and correctly decide questions which have too often, and more frequently of late, led to unnecessary and injurious practices. If we only refer back to these cases, and take one broad view of all the disorders found affecting the uterine system, we cannot but conclude with this firm conviction, that in almost all cases constitutional affections may be detected, not only propagating, but maintaining, local diseases and local derangements; and that our remedies, if their use is to be attended with success, or their administration founded upon pathological investigation, must be directed to the general system—cautiously, if not sparingly, and in most cases not at all, directed to the part itself.

Mr. H. Walton inquired if all the post-mortem examinations enumerated in the paper had been made by the author himself, or by whom had he been assisted? Much of their value would depend upon the examiners.

Mr. Pollock replied that the examinations had extended over a space of ten years, and were not all made by himself; but when he stated that those cases for which he was not immediately responsible, had come under the examination of Mr. Prescott Hewett, Mr. Henry Lee, and Dr. Handfield Jones, he thought that a sufficient guarantee would be given of their authenticity and value. For five years he had himself been engaged more or less in these examinations, partly as assistant-curator and partly as curator. He could therefore personally testify to the accuracy of many of the cases. He had omitted the record of some cases occurring in 1842–43, because they were not examined with that accuracy which was neces-

sary to such an inquiry as the present. Mr. Hewett had first proposed and carried out the plan at present followed in St. George's Hospital. The professional public were much indebted to Mr. Hewett for the example he had set—an example which he (Mr. Pollock) regretted had not been followed by other hospitals.

Dr. J. A. Wilson hoped that there would be no further delay in beginning the discussion on the merits of the facts brought before the Society. The facts, he could answer, might be depended upon. This was an important point in a paper; for as long as he could recollect, even in the old "Lyceum Medicinum Londinensis," after a long narration of a case, there used to be a little doubt of its accuracy, and the discussion flagged. He proceeded to say that Mr. Pollock had dissected under his own eye, and that it was his custom to have all women who died in the hospital examined as to the condition of the uterus and ovaries, whatever might be the disease they died of.

Dr. Murphy had great reluctance in speaking on the present subject, because it unfortunately has happened that in this Society—the first medical society in the kingdom—obstetric questions, or any that have the most remote relation to them, are rather an infliction upon than a benefit to the Society. The physician can have his opinions and practice discussed with all the impartiality and scientific acumen that becomes such a Society; the surgeon cannot complain that his operations or treatment are not fairly considered. In neither case does the discussion assume the character of a personal attack; but let the question concern obstetrics, or be even a third cousin to obstetrics, and the scene is at once changed; the Society becomes excited, its rooms are crowded, there are rumours that some one is to be attacked, and the calm and scientific discussion suddenly assumes all the characters of an angry debate,—of a personal dispute. Dr. Murphy then alluded, as instances, to the former discussions on the speculum, the Cæsarian section, ovariotomy, and would, therefore, gladly have avoided to take part in the present discussion, were it not that this question so seriously affects personal character; were it not that private moral character, as well as professional reputation, may be most easily whispered down if the charge that is implied in this report obtain credence. He called on the Society to recollect the peculiar position of the obstetric physician who had to treat uterine disease. He differed from both the physician and the surgeon in this: he had no witness to testify for him, he had no one to guarantee the truth of his statement with regard to the disease which he treats. The physician, on the contrary, has or may have many. The surgeon could not say there was a fracture when there was no fracture, a dislocation when there was no dislocation, an aneurism when there was no aneurism, without being detected, but the practitioner who has to treat disease of the womb is the confidential attendant of his patient, her complaints are known to him, and to him alone; to communicate them to another is a breach of confidence, to ask the presence of a witness is absurd. Hence two evils of an opposite kind spring up. The practitioner may abuse the confidence reposed in him, he may say that there is disease where there is none, he may submit his patient to a most disagreeable and painful treatment to no purpose, he may make a disease in place of curing one, and thus leave his patient worse than he found her. All this may be done; such (and he spoke on Dr. Copland's authority) has been done, at least in one instance. But he could not think that a man so acting can abuse that confidence long. He trusted to the ill-success of his treatment, he trusted to the intelligence of the female herself, he trusted to the crushing indignation excited by such a discovery, to correct an abuse like this. On the other hand, however, it is equally possible that the practitioner may be an honest man, he may state truly the nature of his patient's complaint, he may employ the most judicious treatment, and may feel—may painfully feel, that he has no witness to testify for him. He may find himself surrounded by rumours that he is treating complaints which have no existence, he may hear that his patient has gone to another, to a rival practitioner, who declared that she had no such disease; he may hear a report industriously circulated, "That at a certain time and place which shall be nameless, a lady whose name we cannot of course mention had been treated by a gentleman, whom prudence forbids us to name, for a disease of the womb, which a most distinguished obstetric physician declared she never had." Nay, he will find these rumours embodied in type, and to his surprise will read the following paragraph in your own Transactions: "Neither in the living nor in the dead body have I ever seen ulceration of the os and cervix uteri, except of a specific character, and especially scrofulous and cancerous, but I have met with a considerable number of cases in which it had been affirmed by others to exist during life after deliberate and repeated examinations by them with the speculum, when I ascertained that ulceration did not exist in the os and cervix uteri, nor disease of any kind. This mistake has happened not once, and to one individual, but in a number of cases, and to several practitioners who avow that they are 'in the daily and almost hourly use of the speculum.'" To say the least of it, this is dishonest. If there be foundation for such statements, let us have the particulars, name, date, place; or if this cannot be done, let there be an umpire—let there be a consultation, where a third party, a man of honour, who will declare who is speaking the truth, is present. Feeling strongly on the mischievous effect of such conduct as this, that it not only most unjustly injures individuals, but is a most serious injury to the profession itself, that it snaps asunder those links of open, manly, straightforward, honourable conduct, which can alone bind an honourable profession together—finding that this report seems to be brought forward to justify such statements, and to "decide questions which have too often of late led to unnecessary and injurious practices," he felt it his duty to watch it most carefully, and to address the Society on the subject. The proposition attempted to be proved is this, that ulcerations of the neck of the womb, inflammations, indurations, hypertrophy—diseases which are said to require the use of the speculum—are very rare diseases; that they are caused by some constitutional affections, and that treatment must be directed exclusively to the general system, and cautiously, if not sparingly, and in most cases not at all, to the part itself. The proof advanced is from certain post-mortem examinations which have been made in St. George's Hospital, not given in connexion with any history of the case, nor of the symptoms during life, nor of the appearances which the parts may have then presented; but just taken as they are from the dead-room, and intended by their number (583) to be a statistical proof that these diseases scarcely exist. The conclusion is obvious, that those who say they are frequent, are either telling untruths, or are ignorant of their profession. Against such evidence he protested *in limine*. He utterly disclaimed as unworthy of confidence, post-mortem examinations, taken separately from the disease observed during life. This objection, strong in ordinary medical cases, has a double force in such cases as are now under consideration,—cases in which we may actually see the morbid changes during life. If the physician could by any means discern the changes going forward, during life, in the lungs, the brain, the kidneys, or the liver, would he fly to the dead-room to puzzle out, amid the dead and semi-putrid vestiges that the disease had left behind, what the disease itself originally was? He asked the President, as a surgeon, would he look for inflammation of the conjunctiva, ulceration of the cornea, ulceration—"so-called ulceration,"—of the fauces, in the dead-room? And if, because they were seldom observed there, not 500, but 1000 post-mortem examinations, were brought forward to prove that they did not exist, would he believe such testimony? And yet we are called upon to believe that inflammation, ulceration, induration of the neck of the womb, but rarely occurs, because in the dead-room of St. George's Hospital they have escaped notice. There is

another *primâ facie* objection to such evidence, in the simple fact, that women so afflicted do not die of such diseases. They very seldom enter general hospitals; and if, in consequence of other complaints, they become inmates, and die there, they are placed under circumstances that would contribute, more than any other, to arrest the progress of the primary affection; they are kept perfectly at rest, and morbid action is going forward in another place. Hence, if they had such a disease, it is highly probable that there would be no trace of it left before death. But he would take the report on its own merits, and distinctly state that he had no confidence in it whatever. It professes to give a return of all the post-mortem examinations (583) made in St. George's Hospital, from 1841 to 1850, a period of nine years, by Mr. G. Pollock, curator. How does this agree with Dr. Lee's statement, in his paper on the Speculum? (Medical Transactions, vol. xxxiii., p. 274). Mr. Prescott Hewett was curator for six years, and in that time examined 600 cases. Mr. G. Pollock, who succeeded, was curator for three years, and examined 300. The periods of both gentlemen, collectively, are nine years; and in that time they examined 900 cases. But it appears that Mr. Pollock, in that time, only examined 583, making a difference of 318 in the female mortality of St. George's Hospital. Again, we find that Mr. P. Hewett could find no ulcerations; Mr. Pollock only four—three scrofulous, the fourth cancerous; but in the present report, Mr. Pollock has found out fourteen distinct ulcerations, neither scrofulous nor cancerous, because these cases are under a separate division. Now let us examine these fourteen cases of ulceration; they are included under the following title: "Mucous membrane of uterus, cervix, os, and vagina diseased and altered in structure," 23 cases; 14 admitted ulcerations; 9 not admitted.

Of these,	Mucous membrane pulpy	1	
,,	Vascular about the os uteri	3	
,,	Mucous membrane congested	1	
,,	Mucous membrane covered with pus ...	1	
,,	White secretion over mucous membrane,	1	—7

Thus of these nine cases, seven gave evidence of preëxisting local inflammation, which we assert to require local treatment. Again, there are twenty-one cases of congestion of the uterus, which it is said, "apparently depended upon, and consisted with, some general constitutional disturbance; the condition itself was not attended with alterations of structure, or indications of incipient disease,"—that is, the congestion was caused by the accompanying disease. Now, which is the more probable—that peritonitis, chorea, rheumatism, pleurisy, disease of the brain, conspired to produce congestion in the uterus, or that the congestion was the last trace of the incipient disease, inflammation, which was arrested by these attacks, and perhaps produced some of them? He claimed, therefore, these twenty-one cases as being at least ambiguous. There are sixteen cases of enlargement of the uterus, of which there is only one where the cause of the enlargement is explained; the uterus being drawn up by a tumour. There are fifteen unexplained, in one of which "the cervix was thickened and elongated." Under the head of "alterations of structure," as of doubtful character, "with some suspicions of cancer," and "dependent on external mischief," there are twelve cases, of which five are cases of induration. The microscope could easily remove the suspicions of cancer. He therefore claimed them also as indurations, the result of inflammation, more especially as one of them is thus described:—"Body enlarged, neck elongated, and structure indurated, the neck and lips extensively ulcerated." Thus we have—

Acknowledged ulcers	14
Doubtful alterations of structure in the mucous membrane	7
Congestions unexplained	21
Enlargements of uterus, not explained	15
Indurations (not cancer) ...	5
Total cases, results of [illegible] ...	62

All these cases, so far as we know to the contrary, may have required local treatment; and so far from agreeing with the author that these cases prove that "constitutional affections propagate and maintain local diseases," the evidence excites the suspicion that the neglect of the local disease may have caused some of the constitutional affections; and hence, although fully admitting the importance of constitutional treatment, he denied that that treatment must be directed exclusively to the general system, and cautiously, if not sparingly, and in most cases not at all, to the part itself. There is one other error in this report that a few words will dispose of: the proportion is taken for the whole number, 583 cases. Now, of these, there were only 265 morbid uteri; 318 were healthy. Dr. Lee, or Mr. Pollock, might just as well give a report of uterine ulcers from the Marylebone Workhouse, and if they found three or four cases in the course of the year, say that they only met with four cases of ulceration in several thousand women, including of course those who had no other disease than inanition. He thus endeavoured to point out the errors of this report, because there is no kind of proof which can be more abused than statistics. "Statistics may be made to prove anything," and nowhere is this skill more shown than in medical questions. Few will take the trouble to examine figures, and conclusions are received as true because they have all the appearance of algebraic accuracy. Thus this question, ovariotomy, the Cæsarian section, and others, have been completely mystified by partial and imperfect statistics. He had stated why he would not take the statistics of St. George's Hospital; but if such an evidence is required, let it be from all the hospitals—from Guy's, from Bartholomew's, St. Thomas's, London. Let it be above suspicion. He was anxious to adopt this method in University College Hospital, but soon found out its fallacy. The very day after Dr. Lee read his paper on the Speculum in this Society, May, 1850, a girl was brought into University College Hospital, who had poisoned herself with opium. A post-mortem examination was made, and he sought for the uterus; it presented an ulcer on both lips of the uterus, extending into the cavity; the pupils present saw it; it was sent to the curator to be preserved, but although every attention was given to it, the next day it lost all its characters, it was thrown aside, and another means of proving the existence of ulceration adopted. Being able so completely to conceal the patient that nothing but the disease could be seen, he obtained the assistance of an excellent artist, Mr. Tuson, to make coloured drawings of these complaints. Mr. Tuson, however, soon found that coloured drawings could not faithfully represent them, and without his (Dr. Murphy's) knowledge made a beautiful series of models in wax, which will speak for themselves. They will show every variety of these diseases, which, in place of being in the ratio of 14 to 583, are more nearly as 1 to 3. In conclusion, he begged to apologise for so long occupying the Society's attention. He wished not to speak, but was placed in this dilemma. If he were silent, it would be said that he shrunk from the exposure made of "certain injurious practices." If he addressed the Society, the question was too serious not to go fully into it. He wished to remove from the minds of society mere prejudices that were excited against a most valuable means of diagnosis and treatment. But while he did so, he begged of the Society not to mix up in their minds two very different questions—the use and the abuse of the speculum. Highly as he valued it, he equally felt the deepest indignation against the man who will dare to abuse the trust reposed in him, who will violate the honour of his profession and disgrace his character as a man. If such a being exist, he trusted that he would be exposed. He trusted that no false delicacy, no feelings of prudence, will prevent the profession expelling him from amongst us. Let this be done, but let not the whispers that such are to be found be made the means of flinging calumnies on those who are honestly following their profession to the best of their ability (cheers).

Mr. Charles Hawkins felt some pain in rising upon the present occasion; he did not do so with the view of discuss-

ing the merits of the paper, with which perhaps he was not able to cope. He agreed, however, with many of the opening remarks made by Dr. Murphy, and regretted that many of the speeches which had been made in that room had tended to lower the profession in public estimation; but his immediate object in rising was to call upon the President to request Dr. Murphy to withdraw the expression "dishonest." In a society composed of gentlemen such expressions were not admitted (hear, hear).

The PRESIDENT had noticed the remark, and hoped that Dr. Murphy would see that it was most injudicious and improper, and that he would withdraw it (hear, hear).

After some further discussion on the point, Dr. Murphy entirely withdrew the expression, and stated that he was most desirous not to use any language which might or could be objected to.

(To be concluded in next Number.)

SURGICAL SOCIETY OF BRUSSELS.

ERECTILE TUMOUR CURED BY VACCINATION.

M. MARJOLIN has brought before the Surgical Society of Brussels a young girl, affording a very remarkable instance of the cure of an erectile tumour by means of vaccination. In 1847 this surgeon had shown this child, then six weeks old, to his colleagues. A venous erectile tumour occupied all the right side of the head and face. The erectile tissue on the one part had invaded the skin of the temples, the margin of the orbit, the cheek, and the lips; and on the other part the mucous membrane of the eye and eyelids, that of the mouth and the arch of the palate. The nearly unanimous opinion of the Society was, that nothing should be done; meanwhile the infant not having been as yet vaccinated, M. Marjolin conceived that he might make use of this opportunity to try the effects of vaccination for the cure of this severe affection. He made twelve or fifteen pricks with a needle round the edges of the tumour, and inoculated each with vaccine matter. The bleeding, although not considerable, was with difficulty arrested. A smart inflammation ensued, which spread over the greater part of the tumour, and extended to the eye, the conjunctiva of which became swelled. These consequences finally disappeared. The infant was taken from the hospital, and was lost sight of for three years and a half.

Then, at last, the mother brought her back to M. Marjolin, who, much surprised at the improvement which had taken place, again showed the young patient to the Surgical Society. The erectile characters of the tumour had nearly entirely disappeared; the erectile tissue had given place on the skin of the head, temples, and cheek, to a white firm tissue. This fact cannot but encourage practitioners to have recourse to vaccination, as performed by M. Marjolin on the circumference of the tumour, and which most surgeons now-a-days advise.

COLLODION USED TO OBVIATE THE GROWTH OF THE NAIL INTO THE FLESH.

M. MEYNIER of Orleans has made a happy application of collodion in this affection. To explain his process, we have only to put back the flesh, and to drop in between it and the border of the nail a small portion of this substance, which quickly dries, solidifies, causes the ulceration to cicatrise, and by keeping the parts separated, ensures the cure, provided the disease does not depend on primative or abnormal deviation in the growth of the nail. M. Meynier himself, who employed collodion thus in five ordinary cases, found it to succeed in four. A method so simple as this deserves the attention of practitioners, as every one knows that when the nail grows into the flesh, how impossible to bear and difficult to cure it is; witness the multiplicity of remedies, either real or imaginary, and the too frequent inefficacy of those, even the most painful and complicated.

SAL AMMONIAC IN INTERMITTENT FEVERS.

M. ARAN has employed sal ammoniac in fourteen cases of intermittent fever. He had collected a greater number, but in twenty-five received into his wards, there were eleven in whom the fever disappeared by repose; and from the fourteen patients, one must be deducted, in whom the accesses were suspended, but the fever persisted. There remained, then, thirteen intermittent fevers treated by sal ammoniac. The method of administering it used by M. Aran was in nearly all the cases the following:—

℞ Ammoniæ hydrochloratis, gr. 124.
Aquæ menthæ,
Aquæ florum aurantii āā. ʒxiv. Misce.

This mixture was given to the patient in two doses, at two hours intervals. After each dose, a small cup of coffee was given, as recommended by Muys, to take away the bitter saline and coppery taste which the medicine leaves behind. The therapeutic results could not be more satisfactory. The thirteen fevers were cut short; seven at the first access, four at the second, one at the third, and one at the fourth. There was a relapse in one case only; that was in a young man affected with paludal cachexia and enormous enlargement of the spleen. M. Aran remarked that these facts, very nearly resembling those reported by Muys, are of a nature to encourage practitioners to persevere in the use of sal ammoniac on account of its low price, its innoxious properties, and its facility of administration.—*Presse Méd. de Bruxelles.*

ORIGINAL COMMUNICATIONS.

ON STEATOSIS OF THE KIDNEY AND APOPLEXY.

By B. WILLS RICHARDSON, F.R.C.S.I.

To Mr. Corfe is due the credit of first promulgating the opinion, that granular degeneration of the kidney depends on the infiltration of its tubules with fat.*

When he first published his opinion, it excited but little attention. Rayer merely alludes to it, and says—"M. Corfe attribue les granulations blanchâtres qu'on observe dans les reins, à un dépôt de graisse on de stéarine dans des conduits de la substance corticale qu'il appelle huileux. Je ne m' arrêterai point á cette hypothese; je préfère remarquer que cet auteur cite plusieurs cas d'hydropisie avec urine coagulable, dont un très aigu et promptement mortel dans lequel les reins avaient une couleur très foncée semblable à cette de la rate."†

The subsequent researches of Gulliver, Davy, Gluge, Constatt, Johnson, and Toynbee, have shown that one or two forms at least of granular disease of the kidney depend on the infiltration of the tubules with fatty or oily matter, and therefore add considerable interest to the doctrine of Mr. Corfe.‡

Gluge describes three stages of the degeneration, and he states that the infiltrated matter is in general oil or fat, stearosis or steatosis.§

In a very interesting paper in a recent number of the *Edinburgh Monthly Journal of Medicine*,‖ Dr. Christison states, that "the congeries of alterations of the kidneys, described by Dr. Bright, depend on at least two distinct morbid processes: one of these is of the nature of inflammation, chronic or acute: the other is a morbid degeneration always chronic, not inflammatory, analogous to what occurs in various other important organs, and consisting of the morbid accumulation of oil or fat globules. The oil globules are deposited in preternatural quantity in the epithelial cells of the urine tubes, distending these cells, detaching them from the epithelial wall, distending consequently the tubes by their accumulation, bursting the tubes here and there, and so escaping into the interstitial tissue. The result of the two processes is, that the function of both the unaffected urine tubes and of the blood-vessels is impeded, and the secretion of urine therefore much disturbed."

* A Popular Treatise on the Kidney: G. Corfe. London, 1839. † Traité des Maladies des Reins, t. II, p. 607, 1840.
‡ Edin. Med. Jour., vol. lxxiii., p. 428.
§ Ed. Med. Jour., vol. lxxiii., p. 451. ‖ June, 1851.

The following case being one of steatosis, and presenting besides some other features of interest, I am induced to publish it. To my friend Dr. Doherty (Professor of Midwifery, Queen's College, Galway), I am indebted for part of its early history.

In the year 1842, Anne Smith, then in her 17th year, having got a fright, the catamenia were suddenly arrested, shortly after which her feet began to swell, and she was affected with pains in her loins, for which she was cupped. The swelling was removed by treatment, but recurred in about one year and a half afterwards, when it was again dispersed. In 1845, she for the first time came under Dr. Doherty's care. She had then an anæmic appearance, and was affected with general dropsy, debility, great drowsiness, sometimes falling asleep unexpectedly, retching, occasional headache, and a dry harsh skin. She menstruated regularly. Her urine was muddy, of a pale colour, acid, albuminous, and its specific gravity 1013. Diaphoretics and diuretics were now given, the latter were limited to infusions of digitalis and juniper, with spt. nit. ether. Her diet was nourishing, but unstimulating. The retching became so frequent it required creasote and prussic acid to allay it. Chalybeates were next had recourse to, with Dover's powder at night. Her pulse at one time during this attack was as low as 46 in the minute. She improved under the treatment pursued, the specific gravity of her urine ranging from 1018 to 1023.

She had several relapses; on one of these occasions, she was given one grain of calomel and twelve of Dover's powder in six powders, one having been taken three times daily. This small quantity of mercury affected her mouth: an additional instance of the great susceptibility of patients affected with morbus Brightii to the influence of mercury.

She was now admitted into the Whitworth Hospital under the late Dr. Green, where she remained but a short time; her loins were cupped, but the dropsical symptoms were not relieved when she left the institution.

In January, 1846, she was again under Dr. Doherty's care. Her symptoms then were, agonizing headache, contracted pupils, drowsiness, and anasarca, with albuminous urine, her face being very much swollen. Leeches were applied behind her ears, sinapisms to her feet, and a blister to the back of her neck, the head was shaved, and a cold lotion kept to it, and some comp. powder of jalap was given her. She improved rapidly, and in a few days she was able to go about. For several months she continued without any marked ailment, but still very pallid, and somewhat œdematous.

She afterwards was under the care of other practitioners, chiefly for the anasarca, and in 1850 I treated her for this symptom. Her legs at this time were enormously swollen, tense, and shining. This subsided, however, under the use of an electuary of bitart. potass. and tart. ferri.

I was sent for to see her early in the morning of the 10th March, 1851. Previous to my being called on, she had been attacked by convulsions, which ceased before I saw her. I found her drowsy, but sensible, with headache, coldness of the surface of the body, and constant retching, her pulse being 52, and pretty strong. The head symptoms were relieved by four leeches, a blister and a turpentine enema, but the retching continued unsubdued by creasote, prussic acid, blistering the epigastrium, and various other remedies, excepting for a few hours on the 13th and 14th. During the evening of the latter day, she was attacked by violent frontal headache, and the retching became as bad as ever. Her face was pale, her pulse weak, her urine was densely loaded with albumen; specific gravity 1015. She was given a draught composed of black drop and prussic acid.

She was relieved in every way by the opiate, having had a good night's rest, her headache greatly lessened, and the stomach being pretty quiet. She was allowed cold chicken jelly, nourishing but light food, and small quantities of wine. Her stomach remained quiet until the 16th, when she had some slight retching and pain in the head. The wine was continued.

On the 17th her head was free from pain, and she retched but twice. On the 18th, her stomach being quiet, she was given five grains of the ammonio-citrate of iron dissolved in water, and sweetened with syrup of orange peel, three times daily. She progressed favourably under the use of these remedies until the 27th, when she had a slight attack of what her attendants called convulsions. Her urine presented the same characters as when last examined. During this illness she required croton oil to free the bowels. Being in a dark ill-ventilated ground floor room, it was thought advisable to have her removed to Sir P. Dun's Hospital, where she remained for a few weeks under Dr. Duncan's care.

She called on me on May the 25th. Her appetite was improved, and she was free from nausea and vomiting, but she looked anæmic, and her urine was charged with albumen; spec. grav. 1015. She told me that her eyelids were puffy in the mornings on first getting up. She hired as nursetender to an old lady, and remained in tolerably good health.

The next opportunity I had of seeing her was on January 16, 1852. She was then free from anasarca, was in good spirits, and had a tolerable appetite, but her urine still contained a large quantity of albumen, and its specific gravity was 1014.

On January 21, 1852, whilst walking in one of the public streets, she was suddenly seized with a violent pain in the head, and fell down insensible. In about five minutes she recovered some slight consciousness, and vomited; she was brought in a car to Jervis-street Hospital, retching several times on the way. When arrived at the hospital, Mr. Dempsey, the resident pupil, found her with the following symptoms:—General headache; pale face; a rapid and feeble pulse; respiration 14 in the minute; cold extremities. She was sensible, but unwilling to answer questions. She afterwards retched several times; then her pupils gradually dilated; her pulse fell in frequency, and her respiration to seven in the minute. She was now in a state of perfect coma. Death took place three hours after her admission into hospital, and exactly three hours and a half from the time of the apoplectic seizure.

My friend, Dr. Neligan, hearing that I was interested in the case, kindly asked me to be present at the post-mortem examination, which was made at ten a.m. next day. The body was pale and blanched; a thick layer of fat existed beneath the integuments, and the omentum was loaded with the same. On removing the skull-cap, the brain did not seem much congested; a small quantity of reddish serum flowed from the arachnoid cavity; this was collected, and on examination subsequently by Dr. Lyons, was not found to contain any urea. The left lateral ventricle of the brain contained a blood-clot, which occupied its body and three cornua, and formed a perfect mould of these parts; this clot was connected with another, placed above the third ventricle. There was a small clot in the anterior cornu of the right lateral ventricle, and another in the fourth ventricle. A thick layer of semi-fluid blood was effused on the forepart of the medulla oblongata,* and a similar effusion concealed the optic commissure and corpora albicantia. The ventricles contained a small quantity of reddish serum; this likewise did not contain any urea. The heart and the liver were healthy. The kidneys were removed, and were examined microscopically by Dr. Lyons, and found to be in a far advanced stage of steatosis.

The prominent points of interest in this case I shall now briefly sum up. First, then, it assists in showing us that life may be prolonged for a considerable time in some cases of albuminuria; indeed, Rayer states† that the duration of chronic albuminous nephritis may vary from a

* In the coma of apoplexy, the respiratory functions are brought to a close by torpidity in the *medulla oblongata*. In the above case, the blood effused on this part must have seriously, if not altogether, impeded its functions.

† Op. cit., p. 125.

few months to many years. "When," says he, "we can remove the patients from the action of the causes which have altered their health—when, by the assistance of proper treatment, we succeed in diminishing the loss of albumen in the urine, or in repairing this loss by a strengthening regimen, if the dropsy has not yet declared itself, or if it has disappeared, the patients may sometimes live in this state, with alternations of apparent health and of dropsy, during a tolerably great number of years."*

I am inclined to think the disease existed in the case just related prior to the year 1842, and that Rayer is not far from the truth in saying that in a great number of instances it is difficult to fix the exact period of the invasion of the disease. Patients generally present themselves when they are already dropsical, and in complete ignorance, not only of the epoch at which the alteration of the urine declared itself, but even of this alteration. Therefore it is absolutely impossible to calculate, even by approximation, the period of the invasion of the disease in individuals affected with chronic albuminous nephritis, with or without dropsy.†

Secondly, it shows us the importance of Mr. Corfe's original hypothesis. I have already remarked that the serum found in the arachnoid cavity, and in the ventricles of the brain, did not contain urea.

Thirdly, it illustrates in a striking manner the second form of apoplexy described by Dr. Abercrombie. This will be seen by comparing the account of the fatal attack in this case with the following description taken from his work.‡ "The second form of the disease begins with a sudden attack of pain in the head; the patient becomes pale, sick, and faint, generally vomits, and frequently, though not always, falls down in a state resembling syncope; the face pale, the body cold, and the pulse very feeble. This is sometimes accompanied by slight convulsion. In other cases he does not fall down, the sudden attack of pain being only accompanied by slight and transient loss of recollection. In both cases, he generally recovers in a few minutes from the first effects of the attack, is quite sensible, and able to walk, but continues to complain of headache; after a certain interval, which may vary from a few minutes to several hours, he becomes oppressed, forgetful, and incoherent, and then sinks into coma, from which he never recovers."

Blood is generally effused in this form of apoplexy, and according to the above writer generally fatal.

Some short time since, I saw another example of this kind which I may be permitted to introduce here. The patient was a boy aged 14; he had been playing with his schoolfellows, when he was suddenly seized with violent pain in the head, vomiting, and convulsions; these were followed by fatal coma, and death took place in twenty-four hours. The brain was literally ploughed up with blood.

The case of Anne Smith shows the fallacy of the popular idea, which associates the occurrence of apoplexy with robust health and general plethora.

The tendency to cerebral hæmorrhage in degeneration of the kidneys, seems to be connected with the cachectic state of the system, as the same liability to apoplexy is observed in cachexia from other causes.

2, North Frederick-street.

Treatment of Sciatica.—Following out the suggestion of Dr. R. Hall in his admirable papers lately published, that we should endeavour to concentrate the diffused experience of the profession upon any practical point in medicine, and thus reduce, as much as possible, facts into the form of laws, I beg to notice the following:—Sciatica, whether connected with rheumatism or not, and not dependent upon mechanical causes, as accumulation of fæces, tumours, &c., may be cured in fourteen days by rubbing along the affected nerve, from its origin downwards, half a drachm of veratria ointment (gr. v. to oz. ss.) every night at bedtime. The friction to be performed with a horse-hair glove until severe tingling is induced.—*Mr. Bree of Stowmarket in Prov. Jour.*

RE-ESTABLISHMENT OF MUSCULAR IRRITABILITY AFTER DEATH.

Dr. Broun-Sequard of Paris, having at his disposal the body of a decapitated criminal, determined to ascertain if irritability could be restored to the muscles by injecting through them freshly drawn human blood. For this purpose, selecting for experiment the muscles of the hand, he employed blood taken from his own veins. Besides succeeding in restoring muscular irritability, he thus made the additional observation, that the blood, although scarlet in hue from exposure to the air before injection, became quite dark-coloured, like venous blood in its passage through the capillaries. It was not till twelve hours and twenty-five minutes after death that all trace of muscular irritability in the arm and hand had ceased, and the injection was commenced forty-five minutes after this. About half a pound of blood, drawn from himself, was defibrinated and filtered through linen. It was freely exposed to the air; as M. Sequard had found by experiment, that in transfusing it is not necessary that the blood should be at the temperature of warm-blooded animals, so that when used it was of arterial hue, and had nearly the same temperature as the surrounding air—viz., 66 deg. Fah. The whole of it was then injected into the radial artery, a little above the wrist, the process occasionally interrupted and resumed, occupying eight or ten minutes. The blood issued black from the veins, also from the ulnar artery, though not to so great a degree. This change of colour could not be owing to the injected blood pushing before it dark blood previously existing in the hand, for the blood which escaped from the vessels, allowed to become arterial and reinjected, again issued black from the veins. This process was repeated several times with the same result. From the commencement to the termination of the injections thirty-five minutes elapsed, of which ten or fifteen minutes were actually occupied by the injections.

Ten minutes after the last injection, muscular irritability had returned to the hand. Having laid bare the muscles of the hand, he observed a considerable variety in their degree of irritability. Of the nineteen muscles, twelve were very excitable; three of these, the first and third lumbricales, and the palmaris brevis, contracting in their whole length from mere mechanical stimuli. The three muscles of the little finger, and one of the muscles of the thumb, were not so excitable; and two of the muscles of the thumb showed no trace of irritability. Perhaps coagulated blood obstructed the vessels of these muscles, or an abnormal distribution of the arteries may have existed. The irritability or non-irritability of the muscles before and after injection, was ascertained by transfixing them through the skin with needles, and then passing a galvanic current. Anxious, however, to discover by actual inspection if any trace of irritability remained before he commenced to inject, M. Sequard laid bare one of the dorsal interosseous muscles. It did not possess the slightest irritability; but in a quarter of an hour after injecting it was very irritable.

The rigidity of death also left the muscles after injection. This was shown by cutting all the muscles of the forearm that send tendons to the thumb and little finger, after rigidity was established, and previous to injecting. The thumb and finger continued stiff and immoveable. But after the injection, the little finger was quite moveable, and the thumb nearly as much so. Two hours after injection, all the muscles were still irritable. An hour and a half afterwards, there were still traces of irritability in the lumbricales and palmaris brevis. M. Sequard's observations were then discontinued till five hours afterwards, when he found that rigidity had returned to a feeble extent in the thumb and little finger.

In comparing these experiments with similar ones upon the lower animals, he concludes that muscular irritability disappears much sooner after death in animals; that while the dead animals receive normal arterial blood projected by the heart of an animal of the same species, venous defibrinated blood, very irregularly injected by means of a syringe, sufficed to restore muscular irritability in the dead human subject. He is of opinion that oxygen is the element of the blood that plays the most important part in this restoration of muscular irritability, of which he is to offer the proofs in another paper.

Twenty-seven hours after death, the experiments were repeated on the muscles of the foot of the same criminal, but with an entirely negative result; with the exception, that the red blood injected issued considerably darker from the veins. —*Edinburgh Monthly Journal.*

CASE OF HERMAPHRODITISM.

Dr. John Neill communicated to the College of Physicians of Philadelphia the following curious example of hermaphroditism, in a black brought to the anatomical rooms of the University of Pennsylvania:—

She dressed as a female, and was apparently 25 or 30 years of age, judging by her teeth and general appearance. Very little information could be obtained concerning her habits and propensities; she resided among the degraded blacks in the lower portion of the city, and died from drunkenness and exposure, according to the verdict of the coroner's jury.

From a superficial view of the pelvis and genitals, almost any one would have pronounced the subject to have been a hypospadic male, notwithstanding the large mammæ and the want of hair upon the face. The breadth of the shoulders compared with the narrowness of the hips, and the form and development of the limbs would, alone considered, have indicated the male sex.

The representative penis was five inches in length and one inch in diameter; and the skin, prepuce, glans, corona, fossa navicularis, and orifice of the urethra presented an appearance like that of a penis; but by lifting up or turning aside the penis, it was found that the fossa navicularis was split, and that the urethra was wanting. In the place of the urethra there was a groove reaching from the glans penis to an oblique opening in the perineum. The cuticle lining the groove was thin and shining; it was also deficient in pigmentary cells. On each side of this groove there was a fold of skin commencing near the middle of the side of the penis, and stretching around the perineal orifice. The interior of this fold showed it to be the analogue of the nymphæ, or corpus spongiosum. The perineal opening was the commencement of a passage common to the bladder and vagina, and its diameter was equal to that of a common sized catheter, although the orifice appeared much larger, owing to its obliquity. The scrotum existed upon one side only; it was corrugated with transverse rugæ, and covered as usual with hairs and sebaceous follicles. To the touch it gave the idea that it contained two hard bodies.

Internal Organs.—These were completely female, though not perfectly developed. The dissection was commenced by opening the abdominal cavity, and the contents of the pelvis were examined in connexion with the external parts. The bladder was natural in position and size; there was no prostate, and the urethra was about one inch in length, and opened into the perineal passage; the uterus was small, but symmetrical; to its sides were attached the broad ligament, holding it in its proper relation to the rectum and bladder; the Fallopian tube of the right side had no free and fimbriated extremity, but terminated in a sac, which was adherent to the ovary; the ovaries were small, spherical, and corrugated; a section exhibited the usual fibrous tissue and vesicles; the right round ligament of the uterus was exceedingly thick, and appeared to be muscular, but upon examination with the microscope it was found to be composed of white and yellow fibrous tissue; it reached to the bottom of the scrotum, where it was firmly attached. The scrotum contained an irreducible omental hernia, probably congenital; the hernial sac contained also a small hardened mass, which was supposed to be a representative testicle, but it contained no true glandular structure or excretory tube; the vagina was of the proper length, but extremely narrow, especially where it approached the perineal orifice.

The above case would be classified under the head of "spurious hermaphroditism" in the female, according to Professor Simpson's article on this subject in the Cyclopædia of Anatomy and Physiology.—*Quarterly Summary of Trans. of the Phil. College of Physicians.*

ON ANTISEPTICS.

By MM. Augend and Robin.

In a memoir recently transmitted to the Academy of Sciences, Paris, M. Augend details a great variety of experiments he has been making upon the comparative antiseptic powers of ether and chloroform, which show those of the latter to be preëminently superior. To completely prevent the decomposition of a piece of fresh meat, 1-200th part of chloroform sufficed. Its vapour traverses the densest tissues; it does not coagulate albumen like creasote, and is not decomposed by the muscular fibre. The most obvious action of the chloroform upon muscular substance and the fleshy pericarp of seeds and fruits is the production of an immediate contraction of the fibre or parenchyma, expelling the aqueous juices to the bottom of the vessel in which the experiment is conducted. M. Augend suggests, among various other applications, that this substance might be found of advantage when it was desired to preserve a corpse for a certain period for the purposes of legal medicine.

M. Robin has conducted numerous series of experiments upon the volatile compounds of carbon and hydrogen, which possess the power of preserving animal substances in spite of the presence of oxygen, as sulphuric ether, chloroform, naphtha, oil of pit-coal, &c. These bodies and their vapours enjoy complete antiseptic power, the blood in the fleshy substance being maintained in quite a fresh state. Water impregnated with the vapour of these hydrocarbonates possesses similar power.

Conducted by analogy of chemical composition, he has discovered another order of substances, possessed of a high degree of antiseptic power—viz., the binary compounds of carbon and some other metalloid than hydrogen. He has proved experimentally that sulphuret of carbon, protochloruret of carbon, azoture of carbon, the Dutch fluid, and hydrocyanic acid, are, like the carburets of hydrogen, powerful preservatives of organic matters. The vapour of these substances, disengaged at the ordinary temperature in closed vessels, preserves such for an indefinite period. For the preservation of the colour of bodies, chloroform, protochloruret of carbon, and oil of pit-coal, are very superior in efficacy to bodies hitherto employed; but they are far from equalling hydrocyanic acid in this respect, the vapour of which absolutely prevents all physical alterations whatever. Nevertheless, in reference to the price of its production, the power and rapidity of its preservative action, no substance presents such great advantages as oil of pit-coal, the rectified allowing much less change of colour than the impure. M. Robin believes it may be advantageously employed for embalming, in the preservation of bodies for dissection, or of anatomical preparations, in the tanning of leathers, for the destruction of insects that attack collections of natural history, trees, or seeds, and for the conservation of cereals, and seeds in general.—*Brit. and For. Med.-Chir. Rev.*

CHARCOAL CUSHIONS FOR DEODORIZATION.

A. S——, a patient under my care in the Hackney Union Infirmary, has for some time "passed everything under her," and thereby become a nuisance and cause of complaint to the other patients in the ward. Eleven days ago, I adopted the plan of placing beneath her a calico bag two feet square, partially filled with Irish peat-charcoal, so as to form a sort of cushion and absorbing medium. It has had the happy effect—which continues even now, without any necessity for changing the charcoal—of completely neutralizing all unpleasant odour; and if the bed becomes partially wet, all the offensive ingredients are absorbed and neutralized by the charcoal, which thus is a most simple means of remedying a great nuisance, and one that requires the most strict attention, at best, to prevent; and that attention is often difficult, and always expensive, to procure. In cases of incontinence of urine particularly, and indeed all attended with fœtid discharges, cancer, compound fractures, &c., this plan, or some modification of it, might be adopted with advantage. I have been informed that some of the same material has been placed in the urinals of the South Western Railway, with equally good result in the prevention of unpleasant odour; and that even after it has been unchanged for some weeks, the fluid that percolates has been found by chemical analysis to contain little or no trace of the organic or saline products of urine. This fact induced me to try it as above. An argument in favour of its adoption in hospitals and lunatic asylums is, that the peat, after its deodorizing properties are exhausted, becomes more valuable for the purpose of manure, so that its use is without expense.—*Mr. Hovell in Lancet.*

[This suggestion seems well worthy of consideration.]

Tartaric Acid used for aiding the Solution of Quinine.—A few drops of dilute sulphuric acid will, as is well known, aid to dissolve disulphate of quinine, but the taste of mixture is then very bitter and disagreeable. Messrs. Bouchardat, Righini, and Ruspini advise tartaric acid to be used for the purpose of hastening the solution of the quinine instead of sulphuric acid; and M. Casorati has found that one grain of the tartaric acid is sufficient to saturate three of disulphate of quinine, the compound being then a sulpho-tartrate of quinine, and not at all unpleasant to the taste.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, FEBRUARY 18, 1852.

THE SHAM SURGICAL DIPLOMA OF TRINITY COLLEGE.

In a former publication we expressed a strong opinion respecting the worthlessness of any surgical certificate or diploma which Trinity College may issue; and notwithstanding all that has since been said and written on the subject (including the asseverations of the "Board" and the "opinions" of "their counsel"), we are prepared to express that opinion still more strongly. That this body may with impunity, like any other body, either corporate or not, certify that a student has been examined and approved, we do not question; but that a certificate to that effect can have any legal value as a qualification to practise surgery, or to fill any public office as a surgeon, we still flatly deny. The uttering of such an instrument as a valid licence or diploma, and as equivalent to the Licence or Diploma granted according to law by the Colleges of Surgeons, may perhaps be held justifiable in a corporation, however unjustifiable it might be in an individual; but be the opinion entertained respecting the morality of the proceeding what it may, there can be no difference of opinion as to the callousness of those who, by such an expedient, endanger the prospects in life of the young and inexperienced. Whatever may be the success of the measures contemplated for restraining the parties engaged in the promotion of this scheme, it is obvious that sooner or later the unlucky student who may be tempted by a pecuniary advantage and relief from an open examination, must be the victim of the litigation which will inevitably follow. An unfortunate young man in narrow circumstances, unprepared to encounter a searching scrutiny as to his qualifications, will perhaps run all risks and accept this equivocal decoration, especially when subjected to the importunities of influential persons; but it is a cruel exercise of authority to sanction such an experiment. If a similar course had not been before pursued by the same parties, we should not perhaps have so much reason to complain; we might in that case attribute it to misconception induced by misrepresentation; but recollecting as we do that several years ago an attempt of the same nature was made and failed, we can with difficulty suppress the feeling of indignation we experience at its repetition. On that occasion the Board of Trinity College, as now, under the influence of its medical professors, offered for acceptance to its "matriculated students" a "Medical Diploma;" a kind of spurious medical degree, called a *Testimonium*, which several persons, in ignorance of its true character, were simple enough to take. In process of time, however, it was discovered that the instrument had no legal value, and did not even authorise the holders of it to retain the title of Doctor which they had assumed under its auspices. The circulation of it was therefore stopped, and nothing more was heard of such expedients until the present time. We have reason to know that we but give expression to a very general feeling when we say that we deeply deplore the circumstances which have led to the adoption of such a course as this by such an institution as Trinity College, and we can only attribute it to an anxiety to relieve their professors from the consequences of the competition they have to encounter. It may, however, perhaps ultimately lead them to comprehend the real nature of their position as regards medical education, and the true character of the proceedings to which they have been made parties. Of the subordinate agents in the affair, we cannot express the opinion we entertain, because we dare not, so unqualified should be the terms necessary to do so: time, however, will effect what we cannot. Sooner or later our brethren, both in the metropolis and the provinces, will learn the particulars of these doings; and sooner or later, we hope and believe, that they will visit with well-merited punishment the authors of them. Over and over again we have endeavoured to impress upon our readers the paramount importance of settled medical and surgical qualifications, and the dangerous consequences of an inroad of practitioners of equivocal professional character into the ranks of our profession, but never have we had greater reason to warn them against such a result than now. To the genuine graduates of Trinity College, and the Fellows and Licentiates of the College of Surgeons of Ireland especially, we would particularly address ourselves, for they are liable to suffer most by this transaction. The Bachelor of Medicine of the University who waited for seven years for his degree, and won it by an honest performance of the exercises enjoined for it, will now not only have to compete with those who obtain it in half the time, and who have been allowed to escape from examinations on the flimsy pretext of attendance on medical lectures; but worst of all, he will find himself presently placed on a level with the illegitimate offspring to whom we have been alluding. The Fellows and Licentiates of the College of Surgeons who paid large apprentice fees, and incurred other heavy expenses to secure a position in our profession, will also presently experience a similar deterioration of character by the juxtaposition of these counterfeits; but doubtless it will be a consolation to them to learn that some of those who benefited by their elevation to that position will now be benefited by their degradation.

PAYMENT FOR MEDICAL SERVICES.

We copy the following to remind our readers of a matter of paramount importance at the present moment. Working for honour and glory in public institutions, and thankye jobs in private practice, have proved ruinous to the medical character; and yet there is no mitigation of the evil. The doctor must be doing, or appear to be doing; and so he volunteers his services rather than remain idle. For this we believe there is no cure; but for the infatuation which leads men to perform laborious and dangerous duties lest some rival should receive payment for them, there is one, for the evil cures itself. The unfortunate volunteer, in fact, finds in the sequel that he takes nothing by his motion. In Ireland in general, and in Dublin in particular, the dispensary act promises to effect a radical change in this respect, and we sincerely hope that our brethren will avail themselves of it:—

The general tendency of recent years has been towards the diminution of gratuitous work by the medical profession. When we compare the sums formerly paid for attendance on the pauper population with the present amount, under the new poor-law arrangements, inadequate as it confessedly is, it must be admitted that a great gain has accrued to the profession. The Vaccination Act, and the Medical Witnesses Act, were large contributions to the professional purse. Such a personage as a medical coroner was formerly an extraordinary officer. There are now twenty-four medical coroners in England and Wales. We may congratulate the

profession upon the immense progress recently made towards the settlement of the question of the payment of medical men by life insurance offices. The profession need only be true to itself to ensure the general concession of this undoubted right. Now, taking all these various items, and some others which might be named, the profession is richer by many thousands of pounds per annum than it was a dozen years ago, or than it could have become in a century without the untiring exertions of an independent press. But we are glad to perceive the tendency towards remuneration is extending in the important direction of our public hospitals and other medical charities, and we desire to urge upon the profession the propriety of seeking, at every proper opportunity, the enforcement of this principle. That medical men can ever be adequately paid for the services they render to the patients in public institutions, is impossible; but we see no reason why, in every case, some salary should not be paid, to mark the public sense of the value of professional labour for our munificently endowed and well supported charities. The treasurers, agents, solicitors, and clergymen of these institutions, are invariably paid for their labours. Why should the medical men alone be so generally called upon for their time and talents, often at the risk of life and health, as a pure gratuity? We rejoice to see symptoms of the extension of the principle of acknowledging public medical services. There are now a considerable number of hospitals and dispensaries in London, where the medical officers receive an annual salary or stipendium. It would greatly conduce to the proper comprehension of this subject, if we could publish a list of all the public institutions in which this good rule prevails. We therefore invite information upon the subject, and if the profession choose to make a moderate exertion, we do not despair of the day when public medical officers will be as generally paid in Great Britain as they are in other European countries. The point is worthy of professional notice, the more so considering that, under any circumstances, a large and liberal amount of gratuitous professional ministration must ever continue as long as the poor do not "cease out of the land." We are especially led to these remarks by the noble example recently set by the Royal Free Hospital, which is an unendowed institution, entirely depending upon voluntary contributions for its support.—*Lancet.*

COUNTRY CONSULTATIONS.

We fear that the following hints may prove of little interest just now, seeing that the necessity which has no law has taught people that medicine and surgery may be practised as effectually in country as in town, and that a physician or surgeon may be just as competent to treat disease in rural as in metropolitan districts:—

With respect to the fees to consulting practitioners, whether physicians or surgeons, summoned in haste from London into the country, it would be very desirable if some scale could be framed approaching to uniformity Now, it frequently happens that in cases where distant consultations are thought desirable, more time is spent in considering about the amount of the fee than in travelling to the place of consultation. It would be fair for all parties—the public and the London and country practitioners—if something like a standard could be adopted. We believe that at the present time the evidence given by Dr. Tyler Smith at the Marylebone County Court, as reported last week, gives a correct description of this delicate matter as it now stands:—"Since the introduction of railways, physicians' fees had varied considerably. In the old days of posting, one guinea per mile was usual. In journeys by railway, physicians, summoned suddenly from their practices in London, now generally obtain two guineas for every three miles; others, high in the profession, considered one guinea for every two miles sufficient Some preferred to be paid according to the time occupied in the country, as three or five guineas per hour. Great injustice would be done to practitioners in the country if physicians took journeys into the provinces from London for low fees." It would be conducive to the interests of the profession and the public, if the College of Physicians took this subject of fees for country journeys into consideration. The discrepancy pointed out by Dr Tyler Smith, is greater than should be allowed to exist. The difference between two guineas for every three miles, and half a guinea per mile, is the difference between £75 and £100 in a journey of 120 miles. The difference of latitude between three and five guineas per hour is still greater. It would be greatly to the comfort of gentlemen practising both in London and the country, if some uniform tariff of fees were agreed upon; and this could come from no other bodies than the Colleges of Physicians and Surgeons combined. For our own parts, we lean to the arrangement of half a guinea per mile. Railways have certainly lessened time and distance by one-half. If such a scale were adopted, the profession in London would be adequately paid, the public would have no reason to complain, and the country practitioner need not fear the too frequent incursions of the Londoner upon his domain. Akin to this subject is the question of how far it is justifiable for consulting London practitioners, whether physicians or surgeons, who are paying short visits into the country, to see patients and take fees, as at their own homes? We know of some cases in which men take their holiday at a particular place every year, and pocket all the fees which come in their way during the vacation. Others, more punctilious, will never see a patient under such circumstances, unless he chance to be their own, or unless their opinions are specially sought by medical men in the neighbourhood. These are points well worthy of attention, as their satisfactory adjustment could not fail to promote the good will and cordial feeling which should exist between professional men, wherever they may chance to reside.—*Lancet.*

DISPENSARY MIDWIFERY.

The following question, before the Belfast Guardians, will prove a test of the practical capabilities of the act. If the district surgeon is to be the ordinary midwife of all poor child-bearing women, he will have ample employment:—

A case was brought under the attention of the board affecting the operation of the medical relief act, and the duties devolving on the medical officers. One of the medical offices of the Belfast Dispensary District, having been apprised by the relieving officer that the *accouchment* of a poor female, in destitute circumstances, would shortly take place, the committee had it suggested to them to inquire whether all *accouchments* of poor persons were to be attended by the medical officers.

Mr. Posnett said that the committee were anxious that the opinion of the commissioners should be obtained as to the construction of the act, and as to whether all such cases of midwifery in the district came within its meaning.

Dr. McGee, at the request of the chairman, then drew up a draft of the case to be submitted for the opinion of the commissioners, and requesting that the board should be informed whether "they should order the medical officers in the several districts to attend all such cases of midwifery, ordinary as well as extraordinary" (oh! oh!).

CORRESPONDENCE.

THE GORT UNION.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I did hope that my letter of the 23rd ult., and your polite note at foot, would have rendered any further interference on my part unnecessary, relative to the report that appeared in your journal of the 21st, in connexion with the new dispensary arrangements of the Gort Union.

I find, however, I have been very much mistaken, and that your correspondent, under the initials of "D. J. H.," in the last number of the Medical Press, still persists in his misrepresentation of me. With respect to the first part of his letter, in which he enters into a defence of himself for reporting those proceedings, I have nothing to do; that is a matter for his own taste and judgment, and I believe one of perfect indifference to the guardians of this union. What I complain of is, that your correspondent should have published that which had no foundation in fact, and (to use his own word) "*cushioned*" that which had. Your correspondent states—"It, however, strikes me the more manly course would have been to state that when the contrary was repeatedly asserted in his presence, and laid down as the

groundwork of the entire proceedings, than to inform us first through the medium of the MEDICAL PRESS."

Now, although I did not feel myself justified in my first communication to allude, even by implication, to the speaker referred to in this report without his sanction, still as the misstatement has been repeated, I feel bound to declare, which I do *most distinctly*, that when appealed to by the speaker in question, *I did object;* and I have the satisfaction to know that there was present on this occasion an officer of the union of high character and veracity, *who heard* my objection. It is possible my words may not have reached the ears of your correspondent, but that can hardly be considered a justification for sending a report to the public press calculated to damage me in the opinion of my professional brethren, without previously consulting me as to the accuracy of a report given from memory. But I have still more to complain of in this report. At a subsequent stage of the proceedings, I, with a view of showing the justice of giving a higher rate of salary than what was mentioned, drew the attention of the guardians to the additional duties to be performed by the medical officer under the new act—say the attendance on bridewells, performance of vaccination, &c.,—and strange to say this *fact* has been "*cushioned.*" Again, at a later period of the discussion, when one of the speakers, *intimately* acquainted with your correspondent, was advocating the claims of the medical officer of the *Kinvara* district to a higher rate of payment than that of the *medical officer at Gort*, on the grounds that the latter enjoyed other salaries from the union, it was observed by a distinguished member of the board—"Recollect if Dr. Nolan has other salaries, he has likewise other duties." This, too, has been conveniently "*cushioned.*"

Now, with regard to my not pursuing "a more manly course," I do not think I have (according to my notions of the term) left myself open to censure on this head. What your correspondent's ideas of such a course may be, I cannot precisely tell, seeing that he has in his own person substituted certain initials for his real name: I confess they appear to me exceedingly equivocal and unintelligible.

With reference to the last paragraph of your correspondent's letter, which appears to me somewhat obscure in its diction, my reply shall be very short and very simple. He proceeds to say, "I will pass over the remainder of his letter without further comment than to express my ignorance of the parties who were *unavoidably absent* when the remonstrance against the reduction of his salary was read, and my thorough knowledge (though *he* seems to forget them) of those who were *designedly present* when a second attempt was made to make a further reduction of £25 per annum in the united salaries of workhouse and fever hospital paid him (notwithstanding his *present* belief that the guardians of the Gort Union are as ready as any other to acknowledge the just principle that each duty should be paid for in regard to itself), and who almost single-handed defeated that attempt."

Now, sir, my reply to the foregoing observations is simply this: My workhouse salary was *never reduced;* my workhouse and fever hospital salaries were *never united;* the motion of the guardians to reduce my salaries was *never defeated*, except by the Poor-law Commissioners refusal to sanction the reduction proposed; and, finally, on *no occasion* that the reduction of my salaries was under consideration was there a guardian present bearing the initials of "D. J. H."

I shall now conclude this correspondence, merely observing that I should never have noticed these communications had they not found their way into the columns of a respectable and extensively read medical publication.—I have the honour to be, sir, your faithful servant,

MARTIN D. NOLAN, M.D.

Gort, February 14, 1852.

A NEW VIEW IN MEDICAL LAW.

AT the Wolverhampton County Court, Mr. Kempson, a surgeon, sued Frederick Woodhall, a miner in the employ of Lord Ward, for £33 18s., being his charge for amputating defendant's leg, for attendance, and medicine. Defendant pleaded *non debet*, inasmuch as he was in Lord Ward's employ at the time of the accident, and that therefore his lordship was bound to pay the bill. Mr. Smith, agent to Lord Ward, argued, *e contra*, that his lordship was not responsible, because, at the time of the accident, the man was not engaged in the mine, but was riding a cart overground when, by his own carelessness, he fell under the cart and sustained the injuries. The learned judge, Mr. Sergeant Clark, adjourned the case, in the hope that the matter might be amicably arranged. It is but fair to add that but one feeling pervaded the court—that Lord Ward was morally bound to pay the bill.—*Lancet.*

RAILWAY PRACTICE.

OUR correspondent ("A Member of the College of Surgeons") is witty and severe upon the subject of "Bus and Railway" diplomas. He states that Mr. —— and Mr. —— both pursue their profession at —— as general practitioners; but that a sixpenny ride by the rail and omnibus to London, converts these gentlemen daily into consulting-surgeons. This metamorphosis is scarcely fair either to the general practitioners of —— or to the "pures" of London.—*Ib.*

M. W. HANLON, M.B.

KILDARE COUNTY INFIRMARY.

NOTICE is hereby given, that the Governors of the County Kildare Infirmary will, on Tuesday, the 13th day of April next, at Twelve o'clock, receive applications and proceed to appoint a fit and proper Person to fill the Situations of Apothecary, Secretary, and Steward to that Establishment. Salary £40 per annum, with liberty to open an Establishment and practise in the town and neighbourhood, so far as that practice will not interfere with his duties in the Infirmary. Personal attendance on the above day will be requisite.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT

G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

AN elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

Extracts and Editorial Note from the New York Journal of Medicine.

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,
"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,
"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

Just published, 8vo, pp. 96, price 2*s.* 6*d.*,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5*s.*,

THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D.,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Twelve months, ...	£1 5 0
Six months, ...	13 0
Three months, ...	6 6

*** Orders to be addressed to Mr. HENRY BEAUMONT, 15, Molesworth-street.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Wednesday, February 18, 1852.

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A.

(Continued from page 38.)

(The Abnormal *Accumulation of Fibrin* within *the Parietes of the Vascular System.)*

In my two last communications we were contemplating the nature of the relation in which the three natural kingdoms—namely, the mineral, the vegetable, and the animal world, stand towards each other with regard to what is termed "*the nutritive process.*" I there (in conjunction with other inquiries) attempted to investigate the three following questions—namely, 1st, the nature of the *first or primary effects* produced upon an inanimate or unorganized world by the operation thereon of *a living or organizing creation;* 2nd, the nature of the *changes* which are *subsequently* wrought in those primary effects by the *further* operation thereon of that living or organizing creation; and 3rd, the nature of the changes which *eventually* take place, in the *final or ultimate results* of such operation, during development of what are termed the phenomena of *animal* life. In relation to these inquiries, I have endeavoured to direct the reader's attention to the contemplation of what had originally been unorganized or mineral matter. 1st, while such matter was in its original unorganized or mineral condition—that is, while existing in that form in which it was *altogether devoid* of what has been termed *organization;* 2nd, during its entire passage or progress through the two departments of *organic* creation; and 3rd, as it began to *descend* in the scale of organization, or while *again* approaching the condition of unorganized or mineral matter. I have endeavoured, I say, in the first place, to trace such matter step by step during its ascent in the scale of organization, watching it *first* in its *unorganized or mineral form,* observing it *then* when but *slightly removed* from the unorganized condition; and from thence following it still further in its progressive ascent till I could see that *same matter*—that is, matter which I had originally seen in the unorganized or mineral condition, eventually (through the agency of *successive acts of generation)* raised to the *highest or most elevated degree of organization* which Nature has designed should be conferred upon mineral matter. Having contemplated such matter for a moment in its *most elevated form,* I have finally attempted to watch that matter *as it began to descend* in the scale of organization, eventually again to become *unorganized matter.*

I have attempted, in a word, to lay before the reader's attention—1st, the nature of the changes which *mineral matter* must *of necessity and indispensably* undergo in order that such matter may become *muscular fibre;* and 2nd, the nature of the changes which *muscular fibre* must *of necessity and indispensably* undergo in order to develop a phenomenon of *animal* life. In relation to these questions, we have seen, in the first place—that is, with regard to the *first or primary effects* produced upon an unorganized or mineral world by the operation thereon of a living or organizing creation—we have seen, I say, in the first place, that it would be altogether irrational to suppose that unorganized or mineral matter could *spontaneously become organized*—could raise *itself* from its unorganized or mineral condition to the condition of matter possessed of even the humblest or lowest conceivable degree of organization. We hence have seen *the necessity* for the existence and operation of certain entities or *agents* endowed by Nature with the faculty of *conferring such organization,* through the agency of which entities the first or primary effects of organization could be produced upon an unorganized or mineral world; or in other words, through the instrumentality of which agents *unorganized* could be converted into *organized* matter. The function of such agents being to *organize*—that is, being to *confer or impart* organization, we have seen the propriety of their being designated *organizing agents.* So much we have seen as regards the cause of the first or primary effects produced upon an unorganized world by the operation thereon of organic creation. We have further seen, in the second place—that is, in relation to the changes which are *subsequently* wrought in those primary effects—we have, I say, further seen, in

the second place, that it would be equally altogether irrational to suppose that such matter, when once raised by those agents to the humblest or lowest degree of organization, could *spontaneously* elevate *itself* in the scale of organization—could raise *itself* from that lowest or humblest degree to the highest or most elevated degree of organization—could, for instance, *spontaneously convert itself* into muscular fibre.

We have seen, I say, that such supposition would be *irrational*, and hence have seen *the necessity* for the existence and operation of *successively ascending* organizing agents, through the instrumentality or agency of which organizing agents the various ascending degrees of organization found to exist in creation have been successively conferred upon what had originally been unorganized or mineral matter. Three such successively ascending organizing agents we have seen in those agents which respectively generate what we term *albumen*, *fibrin*, and *muscular fibre*. We have investigated the functions of those three organizing agents, and inquired where or in what locality those functions are respectively discharged. The *facts* which we have ascertained in relation to these investigations, I shall, for perspicuity, reconsider under the two following divisions—namely, I shall inquire what facts we have learned, 1st, as to the relation subsisting between the organizing agent which generates *albumen* and that agent which generates *fibrin*; and 2nd, as to the relation subsisting between the organizing agent which generates *fibrin* and the agent which generates *muscular fibre*. In other words, the organizing agent which generates *fibrin*, being placed *intermediately*, or as it were *a mean*, between the two other organizing agents *as extremes*. I shall consider this *mean*—namely, the agent which generates *fibrin*—1st, in its relation to one of its extremes; and 2nd, in its relation to the other—that is, 1st, in its relation to the organizing agent by which *its own* "nutriment" (namely, albumen) has been generated; and 2nd, in its relation to the organizing agent *for* which it has *itself* generated the requisite "nutriment"—that is, its relation to the organizing agent which generates muscular fibre. With regard, then, to the former of these questions (namely, as to the relation which subsists between the organizing agent which generates *albumen* and that agent which generates *fibrin*), we have learned the two following facts—namely, that the specific physiological function of the organizing agent which generates *albumen* (which agent I have termed the *albuminous atom*), is to generate what, for perspicuity, I have termed an *organized residual product*, to which has been given the name *albumen*, which albumen has been adapted by Nature for standing in the relation of what is popularly termed "its nutriment" to the organizing agent whose specific physiological function is to generate *fibrin*; and 2nd, that these two agents (namely, that which generates *albumen* and that which generates *fibrin*) exist in *two distinct or separate kingdoms*—namely, the former, or that agent which generates *albumen*, existing in the *vegetable* world; whereas the latter, or that agent which generates the *fibrin of man*, exists in the *animal* kingdom. I would beg of my readers to bear these two facts distinctly in mind—namely, 1st, that *we see* albumen (which *we know* to stand in the relation of what is termed "their nutriment" to animals), that *we see*, I say, such albumen *generated* in the *vegetable* kingdom; and 2nd, that *we see* the *appropriation* of that albumen to the "nutrition" of those animals to take place in the *animal* kingdom. Thus, then, *we see* the "nutriment" of the animal fibrinous atom *generated* in a kingdom altogether *distinct and apart* from that in which *we see* its *appropriation* as the "nutriment" of such atom to take place. And we further *see* (and I would beg of my readers to consider this *fact*), we further, I say, *see* that the *former* of these two processes (namely, the *generation* of albumen) which takes place in the vegetable kingdom, takes place there completely and altogether *independently* of the latter—that is, independently of the *appropriation* of that albumen to the "nutrition" of the animal fibrinous atom. I say that the former of these two processes takes place completely and altogether *independently* of the latter; for it is obvious that the generation of vegetable albumen might go on for a prolonged period uninterruptedly in the vegetable kingdom, even though the animal fibrinous atom had ceased to exist. Thus, then, with regard to the relation which subsists between the organizing agent which generates *albumen* and that agent which generates *fibrin*, we have learned *this unquestionable fact*—namely, that the *generation* of albumen takes place *independently* of its *appropriation*, as the "nutriment" of the organizing agent which generates fibrin; so much so that the former of these processes—namely, the *generation* of albumen—may go on uninterrupted in the vegetable kingdom, even though the latter (namely, the *appropriation* of that albumen to the "nutrition" of the animal fibrinous atom) be for a time altogether suspended. So much we have learned as regards the relation which subsists between the agent which generates *albumen* and that agent which generates *fibrin*. I have been induced to dwell thus long upon the consideration of this relation simply for the following reason—namely, that *identically the same* we shall find to be the case as regards the relation which subsists between the agent which generates *fibrin* and the agent which generates *muscular fibre*—that is, we shall find that the *generation* of fibrin may go on uninterruptedly *within* the vascular system, even though its *appropriation* to the "nutrition" of the extravascular structures be for a time altogether *suspended*.

For let us, in the second place, inquire what we have learned as regards the relation which subsists between the organizing agent which generates *fibrin* and that agent which generates *muscular fibre*. We have learned these two facts—namely, 1st, that the specific function of the organizing agent which generates fibrin (which I have termed the fibrinous atom), is to generate what, for perspicuity, I have termed *an organized residual product*, to which has been given the name fibrin; which fibrin Nature has adapted for standing in the relation of what is popularly termed its "nutriment" to the organizing agent whose function is to generate *muscular fibre*; and 2nd, that the former of these agents—namely, that which generates *fibrin*, is situated in the *interior* of the human vascular system, or at the *internal surface* of the vascular parietes; whereas the latter—namely, the agent which generates muscular fibre, is situated *externally* to the vascular system, or at the *external* surface of the vascular parietes. Thus, then, we see that the "nutriment" of the muscular atom (namely, fibrin) is *generated*, although not exactly in a *kingdom* completely distinct and apart from that in which its *appropriation* takes place; still in a portion of the human mechanism so totally distinct and apart from that in which its appropriation as the "nutriment" of such atom takes place, as to be completely and altogether *isolated or separated* from that atom. We see, in a word, the locality of the *generation* of fibrin completely separated *by the parietes of the vascular system* from the locality in which its *appropriation* takes place. We further see that the *former* of these two processes—namely, the *generation* of fibrin which takes place in the *interior* of the vascular system, takes place there completely and altogether *independently* of the *latter*—that is, independently of the appropriation of such fibrin to the "nutrition" of the extravascular structures; so much so, that the former of these two processes—namely, the *generation* of fibrin, might go on uninterruptedly, even though the latter—namely, its appropriation to the purposes of "nutrition," be for a time altogether suspended.

We see, then, that notwithstanding the close and intimate physiological relation which subsists between the three organizing agents, which respectively generate *albumen*, *fibrin*, and *muscular fibre*; we see, I say, that notwithstanding this relationship, these three entities or agents have been separated from each other by Nature by an impassable barrier or partition—namely, the parietes of the vascular system. *Through* this partition it is *physiologically impossible* that any one of these agents could

pass; I say physiologically impossible, inasmuch as the passage of that barrier would constitute a *pathological* condition. We see the fibrinous atom placed in the *interior* of the vascular system, and we see this vascular system placed, as it were, *intermediately* between the other two atoms. We see *one* of those two other atoms—namely, that which generates *albumen*, placed at *that external surface* of the vascular parietes which communicates with *external* creation; we see the other of those two atoms—namely, that which generates *muscular fibre*, placed at *that external surface* of the vascular parietes which communicates with the *interior* of the animal frame—that is, which communicates with *the extravascular structures*.

We see, then, that the generation of *fibrin* is *dependent* upon the generation of *albumen;* inasmuch as without albumen it would be impossible that fibrin could be generated; but we see that the generation of albumen is in no way *dependent* upon the generation of fibrin, inasmuch as the former of these processes might continue uninterruptedly, even although the latter had ceased. We further see, that the generation of muscular fibre *is dependent* upon the generation of fibrin; inasmuch as without fibrin it would be impossible that muscular fibre could be generated. But we also see—and I would desire to impress this fact upon my readers—that *the generation of fibrin is in no way dependent upon the generation of muscular fibre, but that the former of these two processes might go on uninterruptedly, even though the latter had ceased.*

In relation, then, to the generation and the appropriation of fibrin, we have learned the two following facts—namely, 1st, that *within* the vascular system takes place the *generation* of fibrin, and what, for perspicuity, I would term its *deposition*—that is, its combination with other constituents of the liquor sanguinis of the blood, whereby it becomes adapted for being conveyed beyond the capillary parietes, and for fulfilling the requirements of "nutrition;" and 2nd, that *without* the vascular system—that is, externally to the vascular parietes, or in the extravascular interstices, takes place the *appropriation* of that fibrin to the "nutrition" or *generation* of the extravascular structures.

What, then, do we collect from the contemplation of the foregoing considerations? We collect these two (as I regard them) important physiological facts—namely, 1st, that within the human mechanism there are constantly in operation *two distinct processes of generation:* the one an *intravascular* generation—namely, the generation of *fibrin*, which takes place exclusively and alone (under normal circumstances) *within* the vascular system; the other, an *extravascular* generation—namely, the generation of the extravascular structures, which takes place externally to the vascular parietes; and 2nd, that the *former* of these two processes—namely, the *intravascular* generation, or generation of fibrin, takes place altogether *independently* of the latter—that is, of the generation of the extravascular structures. These two processes of generation (during the *normal* condition of man) are *simultaneously* in operation, and observe a *fixed and constant relation*, as regards the degree of activity or energy with which they are respectively discharged—a relation which has so accurately been balanced by Nature that the amount of fibrin generated *within* the vascular system is (in the *normal* condition of man) *strictly proportional* to the amount thereof *required*, to be appropriated to the generation of the extravascular structures. An *adjustment* of this balance is essential to constitute a *physiological* state; its *disturbance* constitutes a *pathological* condition.

If, then, it be true that fibrin is the "nutriment" of the extravascular structures; if it be further true that such "nutriment" is *generated* and *deposited* in the *interior* of the human vascular system, we may, without the employment of very figurative language, regard *that vascular system* as at once the *garden* and the *granary* of the extravascular structures: the garden wherein the "nutriment" of those structures is *generated;* the granary wherein that "nutriment," when generated, is *deposited* to await the demands of the extravascular structures for its consumption. And what are the *channels or outlets through which* this "nutriment" is conveyed? What, in a word, are the *ports* of its storehouse *through which* it must pass for consumption? They are the *parietes of the capillary system.* Through the capillary parietes, and through them *exclusively and alone*, can fibrin (in the *normal* condition of the system) be extravasated from the vascular system into the *extravascular* interstices. If, then, while the *generation* of fibrin *within* the vascular system is going on *uninterruptedly*, and uninterruptedly continues to be *deposited* within that system; if, I say, while fibrin continues to be generated in *normal* amount, and in normal amount to be *deposited* in the *interior* of the vascular system; if, I say, *at the same* time that such is the case, some obstruction, either total or partial, be placed to *the extravasation* of that fibrin from the vascular system into the extravascular interstices, what must be the obvious and necessary result? The result, as it appears to me, must be obviously twofold—namely, 1st, that fibrin must accumulate to *abnormal* amount *within* the parietes of the vascular system; and 2nd, that the "nutrition" of the extravascular structures must, from a *deficiency* of fibrin, to a proportional extent, *be suspended.*

I shall illustrate for those of my readers to whom I may not convey myself clearly. Let us suppose for a moment, that *corn* is the *exclusive* "nutriment" of the inhabitants of England; let us further suppose, for the sake of illustration, that in Ireland—for though impoverished yet *fertile*, though untilled and forsaken, "*first flower of the land and first gem of the sea*"—let us suppose that in Ireland, not (it may be observed in order to point out the resemblance more closely), not, I say, a *distinct kingdom*, but simply a *distinct and isolated portion* of one and the same kingdom; let us, I say, suppose, for the sake of illustration, that in Ireland is at once the garden and the granary wherein *exclusively and alone* the *entire amount* of the corn consumed by the English is first generated, and then *deposited* to await the demand for its conveyance to *the other side* of the channel by which these two divisions of the same kingdom have been *separated.** Let us, in addition, for the sake of illustration, suppose that the *amount* of corn grown in this country and deposited in our granaries, has been so arranged as to be *strictly proportional* (in the *normal* state of things) to the amount thereof required for consumption at *the other side* of the channel. And, finally, let us suppose that the *sole channel* through which the corn generated in this country can be conveyed into England is St. George's Channel, which *divides or separates* these two portions of one and the same kingdom. If, then (on the foregoing suppositions), while corn continues to be grown in this country in normal amount, and in normal amount to be deposited in our granaries; if, I say, *while such is the case*, some obstruction, whether total or partial, be placed in the channel by which the two divisions of this kingdom have been separated—the *sole* channel through which the corn generated *at one side* thereof can be conveyed to *the other*—if, I say, some obstruction be placed in this channel, whereby the transfer of that corn from *this* to the *opposite* side, be either totally or partially prevented, what must of necessity be the obvious result? The result, as it appears to me, must be obviously twofold—namely, 1st, that corn must accumulate to overflowing in *our* granaries—that is, *at the side of the channel* at which that corn has been *generated;* and 2nd, that the inhabitants of England, *at the other side* of that channel—namely, at the side for which the *appropriation* of that corn to the purposes of "nutriment" was destined; that the inhabitants of England, I say, from a want of that corn must, to a proportional extent, perish of hunger. Let us turn from the contemplation of these two divisions

* I confess that under existing legislative arrangements, it might not perhaps be easy to have selected a *supposed* state of things which could be much more widely remote from the *fact*. Such, however, is immaterial for the purpose of illustration, which the above supposition will serve equally well as though the *supposed* state of things were in *actual* existence.

of the same kingdom to the contemplation of the constitution of *man*, and we shall no longer have a *supposed* state of things to contemplate; but shall *there* find that the foregoing suppositions exist not merely in the imagination, but as *actual realities*.

The corn of our tissues is the fibrin of our blood. The vascular system *is* at once the garden and the granary wherein *exclusively and alone* the *entire amount* of the fibrin consumed by those tissues is first generated and then *deposited*, to await its conveyance to the *other side* of the vascular parietes, to be there consumed or *appropriated* to the "nutrition" of those extravascular tissues. The amount of fibrin generated *within* the vascular system *has been* so regulated as to be *strictly proportional* (in the *normal* state of things) to the amount thereof required for consumption at *the other side* of the parietes of that system. And finally, the *sole channel* through which that fibrin can be conveyed from the *interior* of the vascular system to the *extravascular interstices is* the parietes of the capillary vessels. If, then, while fibrin continues to be *generated*, in normal amount, *within* the vascular system, and in normal amount to be *deposited* within that system; if, I say, *while such is the case*, some obstruction, whether total or partial, be placed in the capillary parietes, the *sole channel* through which fibrin can be conveyed from *one side* of the vascular system to *the other*: if, I say, some obstruction be placed in these parietes whereby the transfer of fibrin from their *internal* to their *external* surface be either totally or partially prevented, what must of necessity be the obvious result? The result, as I conceive, must be obviously twofold—namely, 1st, that fibrin must accumulate to overflowing at the *internal* surface of the vascular parietes—that is, at *that side* of those parietes where its *generation* takes place; and 2nd, that the extravascular tissues at the *external* surface of the vascular parietes—that is, at *that side* of those parietes where the *appropriation* of that fibrin to the purposes of "nutrition" was designed to take place; that the extravascular tissues, I say, must, to a proportional extent, have their "nutrition" suspended.

And what are the causes which could give origin to this supposed state of things? What are the circumstances under which the normal *extravasation* of the liquor sanguinis of our blood from the interior of the vascular system into the extravascular interstices could be suspended; while the *generation* of fibrin within that vascular system is at the same time going on uninterruptedly, and continues to be deposited therein in normal amount? What, in a word, *could obstruct* the transit of that liquor sanguinis through the parietes of the capillary system? It shall be my effort to show that *one* cause of such obstruction is what is termed "*inflammatory action*," and that all causes competent to give origin to what in pathology is termed "*acute inflammatory action*," have a tendency to cause an *obstruction to the passage* of the liquor sanguinis of our blood, *from the interior of the vascular system, through the capillary parietes, into the extravascular interstices*.

If, then, I can show that all causes which are capable of producing what we term "*an acute local inflammation*," tend to a corresponding extent to put a check to the extravasation of liquor sanguinis *through the parietes of the capillary system generally*—that is, through the capillaries diffused universally throughout the *entire* of the system; if, I say, I can satisfy my readers that such is the fact, I shall, as I regard it, have established my first proposition—namely,

"That during acute inflammatory action, there is not (as is, I believe, generally supposed) any augmentation whatever of the normal amount of fibrin contained within the *system generally*; that, on the contrary, the actual amount of fibrin contained within the general system is not necessarily affected in any way by the occurrence of inflammation; but that the *local* accumulation of fibrin—that is, the augmentation (on the occurrence of acute inflammation) of the amount of fibrin normally contained *within the vascular parietes* is the result of the normal extravasation of fibrin from the vascular system into the extravascular interstices having for the time been suspended—that is, the fibrin which normally would have been extravasated from the vascular system into the extravascular interstices (to be there appropriated to the purposes of nutrition) is, during the inflammatory process, retained *within* the vascular system, thereby causing an accumulation within the vascular parietes of that fibrin, which, under normal circumstances, would have existed *extravascularly*."

This brings me to the close of my *first division* of the general subject of inquiry—namely, to the conclusion of my observations upon *the generation and appropriation of fibrin*. I shall next proceed to the consideration of the *second division* of my subject—namely, to an inquiry into *the nature of the mechanism of the human circulatory apparatus*.*

(To be continued.)

* The perusal of the foregoing observations may perhaps (to some of my readers) have suggested the following question—namely, What *practical* deductions are to be collected from all that has hitherto been advanced? What inferences are suggested by the foregoing considerations which can be regarded as of any *really practical* value to the *purely practical physician?* To those of my readers who have habituated their minds to reflect upon physiological questions, it is needless to observe that *every step* made in physiology, in the true path of inquiry, *must* eventually be suggestive of truths of value to *practical* medicine. Lest, however, the foregoing question may have suggested itself to any who may have perused my remarks, I shall endeavour to point out to such *how or in what manner* (as it appears to me) practical suggestions *should be sought for* from all such inquiries. In seeking for inferences from *physiological* researches of *practical* application to *pathology*, the following is the line of inquiry I am in the habit of pursuing—namely, I endeavour to ascertain, 1st, the nature of the *physiological* condition I am desirous of *restoring*; 2nd, the arrangement *Nature has adopted* for preserving that condition; and 3rd, the immediate or proximate cause of the *pathological* condition. I shall apply this order of inquiry in seeking for *practical* suggestions from the foregoing observations upon the generation and appropriation of fibrin. I shall suppose two opposite pathological conditions of the system with regard to the fibrin of the blood—namely, I shall suppose, 1st, that fibrin is generated in *deficient* amount within the vascular system; and 2nd, that fibrin exists within that system *in excess*. First, then, let us suppose that we have learned (from a wasting of the system, from an analysis of the blood, or by any means whatever which could afford such information to the physician), let us, I say, suppose we have learned that fibrin is generated in *deficient* amount in the system. This constitutes the *pathological* condition which it is supposed has first arrested our attention. First, then, the *physiological* condition we are desirous of restoring is *the normal generation of fibrin*; secondly, as regards the arrangement *Nature has adopted* for preserving this condition, we have made ourselves acquainted with the following three facts—namely, 1st, that fibrin is generated by an organizing agent; 2nd, that the "nutriment" of this agent (which latter is situated in the *interior* of the vascular system), that the "nutriment," I say, of this agent (*from or out of which* it generates fibrin) is *albumen*; and 3rd, that albumen is *caused to enter* the vascular system (and there come in contact with the agent which generates therefrom fibrin), that albumen, I say, is caused to *enter* that system by a force of attraction which exists between *albumen* and the fibrinous atom. From this latter fact, we see *a necessity* for the following well-known physiological fact—namely, that when *muscular fibre* has been partaken of as the food of an animal, it must be *reduced* to the condition of albumen in the alimentary canal, in order to admit of its being *drawn* to the interior of the vascular system. So much we have learned as regards the first and second order of inquiry—namely, as to the *physiological* condition we are desirous of restoring, and as to the *means Nature has adopted* for preserving that condition. Let us now, on the application of our *third* order of inquiry—namely, as to the immediate or proximate cause of the *pathological* condition—that is, as to the immediate cause, in the present case, of the deficient amount of fibrin in the blood; let us, I say, suppose we have learned that this pathological condition has arisen *from a deficient amount of albumen having been conveyed into the interior of the vascular system*, which would render it impos-

CURABILITY OF INTERNAL ANEURISM.

By James F. Duncan, M.D.

In your Number of the 11th inst., you have given Dr. Bellingham's able and important paper on this exceedingly interesting subject, read before the Surgical Society at their meeting on the 24th of January. As I had not the good fortune to be present on that occasion, perhaps you will permit me to express through the columns of your journal my deep obligation to Dr. Bellingham for his communication, and for the able manner in which he has treated his subject. I have long been of opinion that medical men are too much in the habit of abandoning as hopeless all cases of thoracic aneurism, whose existence has been established by the improved methods of diagnosis at present in our possession. Anything that tends to dissipate this impression must be productive of incalculable benefit to the interests of science. That cases of aneurism in this situation have been cured can scarcely be doubted; Dr. O'Bryen's paper in the 24th volume of the *Dublin Medical Journal* appears to my mind fully to establish this important fact. In the principles of treatment laid down by Dr. Bellingham, I almost entirely concur. There are, however, two points of considerable practical importance which he does not appear to me to have alluded to, and which, from a case that I had under my care in Sir Patrick Dun's Hospital, about three years ago, appear to me deserving of attention. These are the continued application of cold, by means of pounded ice or refrigerant lotions, to the seat of the aneurism, and the use of a moderate quantity of wine or malt in persons who have been accustomed to stimulants. The former of these I adopted on the authority of Dr. O'Bryen's paper already alluded to, and with the greatest advantage; and the second from reasoning, as Dr. Bellingham has done, that the true principles of cure consist in rest and in having a rich blood of limited amount circulating through the system.

On looking over my papers for the notes of the case, I find that they have been unfortunately mislaid, so that I am obliged to give a brief abstract of its history from memory. It was, however, seen in the hospital by Drs. Lees, A. Smith, Steele, and others, during the period of the man's continuing under treatment. The patient, whose name was Eason, was a Scotchman of between 50 or 60 years of age, a stone-mason by trade, and at the time of his admission, laboured under that form of bronchitis which depends upon the inhalation of the gritty particles of the stone at which he was in the habit of working. His breathing was short and laboured, and there was nothing in his history or appearance to indicate the existence of arterial disease. On examining his chest, however, I discovered an obscure dulness, about the second or third ribs, on the right of the sternum; in this spot there was a distinct impulse unconnected with the heart, and a double bellow's murmur. There was no tumour externally; he had no dysphagia; there was no perceptible difference in the radial pulses at the wrist. Over the entire chest there were sibilant and sonorous râles of varying intensity. The treatment consisted of the application of cold to the spot indicated, which was kept up, with occasional intervals, for several weeks; of perfect rest in the recumbent posture; of a restricted but nutritious diet; of small doses of alum administered internally; and of a small quantity of wine or porter. This was continued for about three months. The impulse gradually subsided, the murmur became less intense, then changed to a single thumping sound, and finally disappeared almost entirely. It became so obscure that but for a knowledge of its previous existence, it would scarcely have been detected. The dulness remained. Meanwhile no improvement was effected in the state of the patient's breathing, but his general health improved. He left the hospital, and after an absence of some two or three months, returned with the signs connected with the supposed aneurism in the same state, but with the pulmonary symptoms increased, and with great increase in the debility of which he complained. After a short residence in the hospital, from which he derived no advantage, he removed to the neighbourhood of Kilmainham, where I continued to visit him in the hope that I might be enabled to satisfy myself, by post-mortem examination, of the precise state of parts in the neighbourhood of the heart, as he was evidently sinking. In this, however, I was disappointed. The distance was too great to allow of my going to him as frequently as was necessary, and on my going out on one day after an absence of about a week, I found that he had gradually sunk from increasing debility and dyspnœa, but without anything to indicate the occurrence of hæmorrhage, and was actually two days buried at the time. The impression conveyed to my mind by this case has been that the aneurism was cured by the deposition of fibrin within the sac, and that in the production of this result the assiduous application of cold to the part had been productive of more benefit than any of the other means employed.

Gardiner's-place, February 20, 1852.

---

sible that a normal amount of fibrin could be generated. Let us further suppose that upon further investigation, we have ascertained the existence of a form of *dyspepsia* (which is well known to the practical physician), in which the *reducing power of the stomach* has been either suspended or so impaired that *muscular fibre* partaken of as food remains in the alimentary canal either wholly or partially *unreduced*—that is, in other words, *unconverted into albumen*, and consequently *incapable* of being eventually converted into *fibrin*. We here recognize the *remote* cause of the lesion which first attracted our attention—that is, the remote cause of *the deficient amount of fibrin in the blood*, and therewith acquire *a practical suggestion*. The suggestion—not, as I regard it, altogether unimportant in its *practical* application—to which I refer is the following—namely, in those forms of dyspepsia wherein the *reducing* power of the stomach has been so impaired as to incapacitate that organ from converting *muscular fibre* into *albumen*, benefit (as I conceive) might result to the *general system*, if (at the same time that the physician directs his treatment to the *removal* of the dyspepsia) a diet of *muscular fibre* be *altogether abstained from*, and in the place thereof be substituted a *purely albuminous diet*. Upon the *nature* of this reducing power of the stomach, as also of the form of dyspepsia to which I refer, I trust at some future period to be permitted to enlarge; at present, however, I have merely referred to the subject in order to enable me to point out to such of my readers as set a value merely upon *practical* facts *in what manner*, as it appears to me, such considerations as the foregoing may be suggestive of *practical deductions*.

Any observations as to the practical inferences to be derived from a contemplation of an *excess* of fibrin in the blood, I shall postpone till we have entered more fully into the *causes* of such excess.

INFIRMARY REPORTS.

REPORT OF THE QUEEN'S COUNTY INFIRMARY FOR 1851.

By John Jacob, M.D., F.R.C.S.I.,
Surgeon to the Institution.

Close scrutiny and investigation of the financial statement of the infirmary for the past year, and of the number of patients treated, will show that the usefulness of the institution is unimpaired, and that the funds have been expended with becoming care. An examination of the accounts, year by year, will prove that such fluctuations as occurred, have depended on the variation of the circumstances and facts of eventful times. Our annual reports have generally been expressive of satisfaction as to the operation of the establishment. They have been truthfully so, because the infirmary has been continuously administered with an earnest desire to render it as useful as possible to the sick poor; while the utmost circumspection has been observed, with respect to the expenditure of the funds, the respectability of the character and appearance of the establishment being at the same time upheld, so as to maintain it creditable to our county, as it has ever been since the period of its erec-

tion. A reduction has been effected in the annual expenditure, though the number of beds occupied has been increased, as has also the number of individuals treated within the year, the wants of the sick poor have been supplied, in so far as this establishment was concerned, every applicant for admission, who was a fit object for an hospital of this class, having been received, while of the hundred beds established in the infirmary, an average of sixty-four and a half only were kept full; there having usually been three wards vacant, and available for the reception of any fit cases that might apply. Due caution has been observed to prevent the infirmary from being burthened with patients, not in need of hospital relief, or who, from the character of their complaints, might be more appropriately located in the hospitals of the workhouses of the county. A sum, less by £200 as compared with the preceding year, was received by presentment. The institution was kept free of debt, which incumbered it for so many years; and a balance retained which enables the governors to seek aid from the county, less in amount by £300, for the ensuing, as compared with the past year. A diminution of no less than £800 in the amount of the presentment for the year having being progressively effected within the last few years, in proportion as the demands on the institution diminished in amount, consequent on a reduction of the population and other causes, concomitant with a considerable abatement of the cost of supplies from the famine prices of a few years since.

It is a gratifying circumstance to observe that an increase has taken place in the subscriptions received for the year. Our year's subscriptions amounted to close upon £150; some considerable arrears of subscription remain unpaid, which are still expected to be received, and will, if paid, restore the list close to the standard of the most prosperous times. A large proportion of the respectable classes of the county know, by observation and experience, that a vast amount of benefit is conferred, by means of the infirmary, upon their humble neighbours when sick, and that considerable satisfaction is experienced by those instrumental in introducing the suffering to the advantages of the institution. Such parties should make known these advantages amongst their friends and urge them to uphold the infirmary by their subscriptions, and thus aid in maintaining it, as at present constituted, a well-ordered asylum for the reception of decent and generally independent poor, when it might be their misfortune to suffer from accident or disease.

A grievous falling off may be observed under one important head of income—petty sessions fines. At one period the receipts by the infirmary from this source, amounted to no less than £156 within the year, and for several years approached nearly to as high a sum, while during the past year, £2 12*s*. 7*d*. was only received. This money previously made available, in a benevolent spirit, for the relief of the sick poor in the district in which offences were committed, and probably where the offenders lived, has been, by a recent enactment (14 and 15 Victoria, cap. 90, sec. 13), transferred to the crown. In fact this means of support to local charities has been withdrawn from this impoverished country to add to the store of the nation's wealth. Henceforward this item will probably no longer be found in our accounts.

An act of parliament, introduced and conducted by the Right Honourable Sir W. Somerville, Chief Secretary for Ireland, and Member for Drogheda, having passed the legislature last session, which has altered the preëxisting arrangements for medical relief of the poor by means of dispensaries, and which also exercises some influence upon the interests of infirmaries, it would be a serious omission, a dereliction of duty, to pass it unnoticed in what should be a faithful history of all important facts relating to the infirmary which may have occurred within the year. In the form in which the act passed, it bears upon the infirmaries in two particulars only, the subjecting them to the visits of the inspectors under the act—an arrangement to which no reasonable objection could exist; the other, much to be lamented under all, but more especially the present circumstances of this country, prostrate as it is from a visitation of Providence, which, by its results to all classes, will mark this century as the period of the greatest of the tragedies of Irish history The withdrawal from all county infirmaries, after the existing surgeons shall cease to be connected with the institutions, of the trifling aid which these establishments, of truly national importance and usefulness, had previously received from imperial funds, of the hundred pounds per annum late currency voted by parliament, in the fifth year of the reign of George the Third, to pay the salary of a surgeon, taken in connexion with the transfer of petty sessions fines from the relief of the sick poor, must be considered as events to be deplored, let them be viewed how they may. It was certainly no boon to the Irish charities to throw the charge of the salary of future surgeons as an increased burden on the general funds of the institution. Had the bill, in the form in which it was introduced into parliament, become the law, our infirmary would, before this time, have passed from the hands of those by whose liberality it was erected and who have been supporting it for a long series of years by benevolent and voluntary contributions. It is no vain boasting to state that this infirmary has ever maintained an honourable distinction. With its earliest history distinguished names have been associated. It rose under the patronage and care of a brother of the noble veteran who is recognized by all as the most distinguished in the empire, beyond the pale of royal connexion. It has been liberally and continuously supported by one of the most respected and esteemed of the members of the present administration; and it has been firmly, perseveringly, and successfully defended in parliament, by the three members sent by the Queen's County and Portarlington. The Hon. Thomas Vesey, the Right Hon. J. W. Fitzpatrick, and Colonel Dunne, all sustained the rights of the governors and the interests of the sick poor, the first and last of these gentlemen having firmly resisted, to the end, and triumphantly, the transfer of the infirmary from the hands of those who cared for the sick poor, when unprovided with other means of relief—a service in which they were ably assisted by Lord Naas.

The total number of indoor patients treated amounted to 825, of outdoor to 2497. Of the indoor 522 suffered from diseases designated surgical; 138 cases were of the mixed medical character, and 165 were fever; 554 were discharged cured; 188 were made outdoor patients, and 29 died, 54 having remained at the end of the year; close on 500 of the 825 were received from districts beyond five miles distance from the infirmary—"facts and figures" which disprove the assertions, inaccurately made, that the benefits conferred by the infirmary were limited to the districts contiguous to the institution. Within a period of ten years terminating at the end of 1851, 4274 persons were received as *indoor* patients from within a circle of five miles radius round the infirmary, 4413 from a circle outside five miles and within a radius of ten, and 2540 from beyond ten miles; 6953 having been taken into the house from beyond a distance of five miles within ten years. The cost of relief was little over £14 for each bed occupied during the year, and £1 2*s*. for each individual treated indoor.

It is worthy of notice that outdoor patients continue to attend the infirmary from all parts of the county, even the most remote; and that both subscribers and patients appear to value the arrangement to afford advice and medicine to such of the sick poor of the whole county as may apply.

If an anticipation may be offered of the prospects of the infirmary for the ensuing year, it may be of rather a cheering character. There is reason to hope that the pressure on the institution may be moderate, with funds sufficient to meet all reasonable demands. The late contract taken for milk may be expected to effect a saving of about £80 within the year.

The following abstract presents at one view an outline of

the more important facts relating to the operation of the institution for the year:—

Number of beds in general medical and surgical hospital	64
Do. in fever wards	36—100
Average number of beds full throughout the year in general hospital	52½
Do. do. in fever wards	12—64½
Number relieved by each bed in general hospital within the year	12½
Do. do. in fever wards	13¾
Average number of days each patient was under treatment in general hospital	29
Do. do. in fever wards	26½
Total number of patients treated in general hospital in the year	660
Do. in fever wards	165—825
Of whom were admitted from within a circle of five miles radius round the infirmary ...	347
From between five and ten miles	286
Beyond ten miles	192
Number of individuals treated as extern patients	2497
Number of prescriptions of advice and medicine to extern patients	5080
Number of domiciliary visits to sick poor of the town and vicinity	315

The following averages of expense have been struck according to two methods. The first charging the entire amount of expenditure, including the cost of relief of out-door patients at the infirmary, and the domiciliary attendance which the sick poor receive at their own houses, and the attendance of the infirmary surgeon on the gaol, for which no remuneration is received. The second, more correctly, making a deduction of £150 for dispensary expenses, and of £65, the sum allowed by act of parliament for medical attendance on the gaol, but not granted. In the second calculation, the intern patients are charged with those expenses only which were incurred exclusively on their account:—

Total amount of expenditure within the year,	£1121	15	7
No. 1. Average cost of each bed full during the year (charging cost of medical attendance on gaol, dispensary, and domiciliary attendance at the houses of the sick poor) ...	17	7	10
No. 2. Do. do. (deducting £150 on account of dispensary, and £65 for medical attendance on gaol)...	14	1	2
Average cost of each individual treated (calculated according to No. 1)	1	7	2¼
Do. do. (calculated according to No. 2)	1	2	0

February 21, 1852.

LONDON HOSPITAL REPORTS.

THE MIDDLESEX.

Morbid habit of swallowing Hair.

By Dr. Crawford.

Dr. Thompson has alluded, in this journal, to the case of a girl who used to swallow her hair, and had lately vomited packets of it. The patient has, since then, passed, per anum, a large mass of the same organic product; this circumstance induced us to inquire more minutely into the case, and we learned from the girl the following facts.

She is a servant, aged 23, now pale and thin, but formerly ruddy and stout, and was admitted November 16, 1851, under the care of Dr. Crawford, with very obstinate constipation. The patient began to menstruate at the age of twelve years, and at thirteen, while in a comfortable situation, contracted the habit of picking off her hair, biting, chewing, and at last swallowing it. She went on satisfying this depraved taste for four or five months, when, being reprimanded, she gave it up, and has never resumed the custom since.

Soon after this, the patient began to feel a pain under the false ribs, on the left side, just over the spleen and the large extremity of the stomach. She was treated in various ways, and at different hospitals and dispensaries, during several years, for this pain, no one, nor herself, suspecting that the above-mentioned habit was the source of her malady. The general belief was, that she suffered from a tumour in the vicinity of the spleen; pain in that region, constipation of bowels, and wasting, being the principal symptoms.

At last, about a fortnight before admission, she was seized with fits of vomiting, and, among the rejected matters, a solid concretion, about the size of a walnut, was noticed; but this attracted no attention, until a second and much larger one was likewise brought up in the hospital. The nature of the affection became now apparent, but the constipation was very obstinate, and went so far as to produce stercoraceous vomiting. No more hair was noticed after these symptoms abated, until January 26, about nine weeks after admission, when a very large hairy concretion was discovered in the fæces. It was of the size of the dilated rectum, measured five inches in length, and was of a deep black colour. (The girl's hair is of a light tint.) The patient states that she felt this in the right iliac fossa, and she is now under the impression that more hair will be evacuated. The health has of late been rather weak, but the appetite is pretty good, and the intellect clear; but the patient complains of flatus, and of the bowels rolling in knots. This is another and very striking example of the difficulty of treating disease, when we do not know *every particular* of the history.

Encephaloid Cancer mistaken for Aneurism.

By Mr. Moore.

We pointed out, in a late number, that a case of aneurism of the arteria innominata had been admitted into this hospital, under the care of Mr. Shaw; another patient, supposed to be affected with the same arterial disease, has since been received; but it was the external iliac artery which was thought to have suffered in this latter instance. The patient, a man aged 52, was admitted, January 20, 1852, under the care of Dr. Seth Thompson, for pain and swelling of the left leg.

The limb had been œdematous, and the skin permeated with large veins, for about ten weeks before admission; and it was soon discovered that this state of things was owing to the existence of a pulsating tumour situated within the abdomen, and easily felt between the umbilicus and Poupart's ligament. The patient was now transferred to Pepy's ward, and placed under the care of Mr. Moore. The tumour could be distinctly felt through the abdominal parietes, lying in the course of the external iliac artery, and yielded to the hand a strong pulsation, synchronous with the cardiac action. The tumour and the pulsation increased rapidly; and as there was no distinct evidence of their being other than aneurismal, and a preponderance of opinion that they were of that nature, Mr. Moore proceeded to the deligation of the common iliac artery. The pulsations of the tumour ceased immediately, and the patient went on pretty well for a little while; but his system seemed unable to resist the shock of the operation, and he died a few days after the deligation of the vessel.

On a post-mortem examination, it was found that the tumour was of the encephaloid kind, and lay between two large arteries, which had communicated to the tumour the pulsations felt during life. It will be recollected that unavoidable errors of this kind have happened once or twice before in our hospitals; and it is plain that the most careful examination, and the most consummate surgical skill, can hardly preserve from such misapprehensions (notwithstanding stethoscopic skill).

ST. MARY'S.

Removal of Exostosis of the Orbit.

By Mr. Haynes Walton.

Two cases have lately been treated at this hospital; they will show forcibly how different are the manifestations in different subjects consequent upon irritation of parts. In fact, it

would appear that before long we shall be driven back again to an almost purely humeral pathology, for how could otherwise be explained such phenomena as these? Three persons, in apparent health, receive an accidental blow, or meet with a slight bruise, on some portion of the body. One hardly notices the circumstance; the healthy process of inflammation, and subsequent cicatrization, are rapidly gone through, and no trace of the accident is left. The second sees a slow and sluggish congestive inflammation take place, an unhealthy discharge follows, and if a joint have been implicated, there is much likelihood of its complete disorganization. The third experiences little or no pain, but after some time the part becomes indurated, inflammation slowly sets in, and the ulceration which ensues assumes the unmistakable characteristics of a cancerous fungosity.

We shall be told of course, that the first individual was in perfect health; that the second was under the influence of the scrofulous, and the third of the cancerous, diathesis. But what is the nature of this diathesis? In what structures does it lie? Can its principle be isolated, either from the solids or the fluids? Can we chemically or microscopically discover it before any tangible manifestations have occurred? Shall we rely on the theory of retrograde metamorphosis, so cleverly advocated by Dr. T. Addison, in his work on Scrofula? Whichever way these questions may sooner or later be solved, it is extremely probable that, by the aid of chemistry and the microscope, the fluids will be found at fault. But we at once proceed to narrate the case; it will certainly prove replete with useful suggestions.

Case.—Exostosis.—E. H——, aged 40, a carter by trade, fell down stairs a few years ago, and struck the edge of the orbit against a hard substance. In the space of about two months an enlargement of the part began to appear; it was at first but small, but it gradually increased, and within about three years the eye was overhung with a hard tumour, evidently an osseous growth, which so much intruded on the orbit as to compress the eye, threatening by its further development to destroy vision.

Under these circumstances the patient applied for relief, and Mr. Walton, after carefully examining the part, thought that it was imperative for the safety of the eye that the exostosis should be removed. The characters were not surrounded by any doubt; hardness, immobility, slow growth, continuity with the bone, absence of pain and inflammation, &c., were all sufficiently marked. The patient was therefore brought into the theatre, in July, 1851, and having been narcotized with chloroform, Mr. Walton made a crucial incision over the tumour; the growth having then been isolated, it was removed from the edge of the orbit by means of a small saw. The parts were brought together in the usual way; the inflammatory action did not run very high, nor materially interfere with the globe of the eye, though that organ was so near the parts operated upon. After a few weeks the patient was discharged, and up to this period has done well, no tendency to a recurrence having been manifested.

GUY'S.

Excision of a Pen-holder from the Urethra.

By Mr. BIRKETT.

We put upon record some time ago, a case of extraction of a fragment of catheter from the bladder under the care of Mr. South, at St. Thomas's Hospital. It will be recollected that the patient recovered perfectly, and that no small difficulty was experienced in removing the foreign body. A case of a somewhat similar kind, though less formidable, occurred lately at Guy's Hospital; Mr. Birkett succeeding likewise [illegible] by extracting the extraordinary object which had [illegible] into the patient's urethra. The facts are these:—

C. S——, aged 25, a waiter at a coffee-house, was admitted into Philip ward, under the care of Mr. Cooper, October 17, 1851, in consequence of having passed a piece of wood into his bladder. The patient is a spare, delicate, irritable, or rather excitable man, hard worked, but living well. He has enjoyed good health, and has never had any venereal disease whatever. About four months since, he experienced a difficulty in micturition, and only passed a little urine at each effort. After his urine had cooled, a pink sand and a quantity of thick matter (probably mucus) used to adhere to the bottom of the vessel. Such was the state of the renal secretion on the evening previous to his admission, when thinking (as he states) "to stir up the sand and get rid of it at once," he introduced the holder of a "magnum bonum" steel pen into his urethra. The piece of wood slipped from his fingers, and in his efforts to withdraw it he pushed it farther into the canal.

In the absence of Mr. Cooper, Mr. Birkett first saw the patient about ten a.m. The end of the piece of wood was easily felt in the urethra when pressure was made in the perineum, and Mr. Birkett tried to extract it by the meatus with long forceps. He readily grasped and caught the wood, but was unable to draw it forwards, as the forceps slipped off it when traction was made. Fearing to lacerate the urethra by these manipulations, Mr. Birkett incised the perineum over the projection caused by the end of the piece of wood, about a quarter of an inch behind the scrotum, and extracted the pen-holder.

The man had not stated the nature of the foreign body in such a manner as to lead any one to suppose that it was so long; or, as Mr. Birkett observed afterwards, it is probable that by depressing the end which was in the bladder from above the pubes, the anterior extremity might have been so influenced as to enable him to withdraw it by the urethra. As it was placed, however, the more forcible the traction, the more firmly it became impacted against the floor of the urethra. The patient was evidently suffering from chronic catarrh of the bladder, and to improve this condition he was ordered, at the suggestion of Dr. Rees, saline mixture, one ounce, tartrate of potash, one drachm, three times a day.

The incision, which for a little while allowed some drops of urine to pass through the perineum, cicatrized in about ten days. The urine soon assumed its normal characters, the patient's health improved, and he left the hospital quite well. There was at this time no impediment to the passage of a full-sized elastic catheter.—*Lancet.*

ANEURISM OF THE AORTA BURSTING INTO THE TRACHEA.

By Dr. W. H. GOOCH, of the Kent and Canterbury Hospital.

THE subjoined case was read to the East Kent and Canterbury Medical Society, and is an instructive example of aneurism of the arch of the aorta, which was not discovered during life, but produced symptoms resembling those of chronic laryngitis.

A carpenter, married, aged 44, of strumous habit, middle sized, and temperate, was admitted September 20, 1850, into the Kent and Canterbury Hospital. It appeared that about a twelvemonth previously he fell from the top of a house, and soon afterwards spit a little blood; the hæmorrhage, however, did not return. Four months afterwards he began to complain of a sense of fulness and tenderness about the upper part of the windpipe, which he attributed to a neglected cold, as he coughed a little at the time. Nothing was done for the relief of these symptoms for three months. He was then blistered, the medical attendant regarding his complaint as inflammation of the chest. No relief ensuing, he sought admission into the hospital. He was then reserved and dejected, and much wasted. He complained chiefly of a sense of obstruction behind the thyroid cartilage, with tenderness and soreness in that situation when he spoke or coughed. The cough was hoarse, and often shrill, and at the end of each fit of coughing the breathing became extremely hurried, especially at night, so that he could sleep but little. His voice was hoarse, and sometimes whispering, and he expectorated a scanty frothy mucus.

Auscultation disclosed a feeble respiratory murmur throughout the *left lung*, particularly at its apex, without rhonchus. The vocal resonance was morbidly loud, and the sound on percussion dull anteriorly and posteriorly. In the *right lung*, with the exception of a little sibilous rhonchus in the upper lobe, the sounds heard by the stethoscope, and percussion, were natural. The systole of the heart was feeble, but the sounds and rhythm were healthy. No unnatural arterial pulsation was discovered anywhere. The pulse was 84, soft, and weak. The appetite was impaired, but the tongue looked clean.

Considerable relief was afforded by cupping in the interscapular region, by counter-irritation on each side of the larynx, and by mercurials, with expectorants and sedatives. Dyspnœa was alleviated, and sleep secured, by a nightly dose of chloroform. Slight œdema of the ankles now appeared, but with that exception the patient had improved and gained strength, from a nutritious diet and cod-liver oil, when soon after midnight of the 23rd of November he was seized with a sudden and very violent fit of coughing, during which an enormous quantity of blood rushed from his mouth, and he was dead in an instant. A slight aggravation of the cough had been noticed for a few days before the awful event.

Post-mortem examination second day after death.—The larynx and trachea showed no marks of disease. The *right lung* was emphysematous, and did not collapse when the chest was opened. The lung at its upper part was adherent to the costal pleura by long bands of lymph, both anteriorly and posteriorly. Several large red patches were scattered over the surface of the middle and lower lobe, which condition was thought to depend on the entrance of blood into the minute divisions of the air tubes, several small coagula being found in the larger bronchi. The *left lung* was universally adherent by a thick firm layer of lymph, and did not crepitate, the whole of its tissue from apex to base being in a state of gray hepatization. Three or four cretaceous deposits were found, of the size of half a gray pea, on making sections of the lung. The bronchial ramifications appeared dilated, and their lining membrane thickened, and intensely injected. The pericardium contained the usual quantity of fluid, and presented some white fibrinous patches on the surface of the right ventricle, together with adhesions between the surfaces at the base, around the great vessels. The heart was somewhat large, but its cavities and valves were natural. The aorta presented in its first portion patches of white thickening of the inner coat, and atheromatous deposits, and at more than one spot a circumscribed superficial dilatation of the coats had taken place. Immediately beyond the left subclavian artery there appeared a large opening, that would readily admit the fore-finger, which communicated with an *aneurism*, of the size of a small orange; it was situated between the aorta and trachea, and contained a small loose mass of fibrin, but had no concentric laminæ. The rings of the lower part of the trachea were bare in the posterior wall of the sac, for a space equal to the circumference of a sixpence. At this spot there were two distinct openings that passed into the trachea at its bifurcation, one of these, more properly speaking, led into the commencement of the right bronchus. The margins of these openings on the tracheal side were surrounded with tufts of lymph, adhering pretty firmly. The left recurrent nerve, after passing round the corresponding bronchus, became embedded in the wall of the aneurism. The glands between the bronchi were much enlarged, and filled with a hard cretaceous substance.

In reflecting on the case now detailed, one cannot fail to be struck with the undoubted relief afforded by the treatment to the more urgent symptoms, at the same time that the aneurismal disease must be considered to have been advancing. To the congested and hepatized condition of the lungs diagnosticated during life, and discovered after death, we may point as satisfactorily explaining this apparent anomaly.

But the great practical lesson which the case suggests has reference to diagnosis; fresh proof is afforded by it of the obscurity which surrounds the progress of aneurisms about the commencement of the aortic arch. In the majority of instances the symptoms that result from compression of the surrounding organs, offer only equivocal evidence; it remains for a pulsating tumour, or a sudden arterial hæmorrhage, to reveal the true nature of the affection. Sometimes, indeed, the trachea, the œsophagus, or the recurrent nerve, sustain such impediments to their functions from pressure, that the diagnosis is not a matter of difficulty. On the other hand may be cited, as a striking contrast, the case recorded by Mr. Lawrence in the Medico Chirurgical Transactions, vol. vi., where an aneurism of the arch of the aorta so pressed on the trachea as to ulcerate its lining membrane, and yet the patient did not experience any dyspnœa, death arose from a different cause, and the discovery of the aneurism, which was small and filled with firm laminated coagula, was quite accidental.

Laennec, when speaking of aneurism of the thoracic aorta, remarks—"It cannot be known with certainty till it shows itself externally; it can hardly be suspected even when it compresses some important organ and greatly deranges its functions."

And in support of the same doctrine, the case of the late Mr. Liston may be adduced. At first, it will be remembered, his symptoms were attributed to tubercular condensation of the superior lobe of the lungs. It was thought doubtful whether the dyspnœa depended on enlargement of the bronchial glands, or on aneurism; the latter was only suspected by the distinguished physicians in attendance. This suspicion proved to be correct, for a false aneurism of the aorta was found of the size of an orange, which had burst into the trachea, and, of course, had led to the copious hæmoptysis that took place five months before death.

In the Catalogues of the Museum of the Royal College of Surgeons, and of St. Bartholomew's Hospital, three cases of aneurism pressing on the trachea are described, in two of which an opening was made into the trachea to relieve the symptoms.

In the instance under consideration, the absence of all physical signs indicative of disease of the heart or its large vessels, the evidence of solidification in the left lung, the peculiar character of the voice and cough, with other symptoms, led to the inference that the chief lesion was strumous laryngitis, probably advanced to the ulcerative stage (with preëxistent pneumonia).

Post-mortem examination corrected the error by discovering another and an adequate cause of the affection of the throat, in the fact of the recurrent nerve being involved in the aneurismal sac; while the condition of the left lung, and the position of the aneurism, explained the paroxysms of difficult breathing.

It is right to add that a suspicion of some unusual pressure upon the recurrent nerve, like that which would be caused by enlarged bronchial glands, had been expressed by me shortly before the patient's decease.—*Prov. Jour.*

Hæmaturia.—Dr. Rees mentions two forms of hæmaturia; the one produced by calculus in the kidney, and the other by malignant disease. The same remarks made with regard to alkaline urine from irritation of the mucous membranes, may be applied to the presence of a calculus in the kidney. Our object must be to render the urine as unirritating to the mucous membrane as may be, and enable that membrane thus to bear the presence of the calculus with as little inconvenience as possible. To relieve the spasm of the canal, we should combine alkaline and demulcent remedies with such sedatives as the patient can bear without injury to the stomach. The best styptic is perhaps tannic acid; it should be given in the form of pill, at intervals between the doses of iron, in doses from four to eight grains three times a day. It should not be given in solution, on account of its being rapidly converted in the stomach into gallic acid.

REPRODUCTION OF LACTATION.

By Dr. Ariel Ballou, of Rhode Island, U.S.

Case 1.—In the autumn of 1836, Mrs. J. G., aged between 30 and 40, of sanguine temperament, robust constitution, and the mother of several children, was confined. The presentation was natural, and no unusual circumstances attended her delivery. Subsequently she suffered from an attack of phlegmasia dolens in both of the lower extremities, attended with high febrile action, and, as is usual in such cases, extreme suffering. The secretion of milk ceasing early in the disease, the child was removed to a wet nurse, with whom it remained three or four months, during which time there was no return of milk. In the spring of 1837, the family being about to move a short distance from the village, where they could enjoy a better air and a more unrestricted exercise, the mother was anxious to take her infant with her, but did not like to deprive it of the advantages of the breast during the then coming warm season. I advised the mother to take her child and apply it to the breasts in the same manner she would do if she had a flow of milk; assuring her it was my confident opinion that in two or three weeks she would have milk, and a sufficient quantity, at least her usual supply. She did so, and in about two weeks the secretion of milk was reproduced. She continued to nurse her child for more than a year, producing her accustomed quantity of milk.

Case 2.—Mrs. N. D., aged about 25, was confined in December, 1841. Nothing worthy of note transpired during her confinement and recovery. In April following, her child weaned itself in consequence of a sore mouth. Her milk soon entirely disappeared. In July following, I was called to see her child, which was suffering from an attack of cholera infantum. Having lost several children about that time from this disease, I expressed my regret that the child was deprived of the benefits of the breast, adding that, in my opinion, its chances of recovery were diminished in consequence. The mother was informed of the course I had advised in other cases where it was desirable to reproduce the secretion, and of the results. On my visit the succeeding day, she informed me that she had applied the child to the breasts, and that it nursed, and seemed pleased and more quiet; but she was not aware that any milk was obtained, or that she had any for it. I advised her to persevere in the application of the child to the breasts, which she did, and the child recovered, and in the course of a week or ten days obtained a full supply of nutriment from the breasts. The mother continued to nurse for months with as full and perfect a secretion of milk as though no interruption in the secretion had occurred.

The following case I report as having an important practical bearing on the treatment and disposal of a class of cases which occur in our community at the present day, to cure which, or otherwise dispose of satisfactorily to the physician, is often found difficult.

Case 3.—Mrs. O. H. H., aged about 21, of feeble constitution, and nervo-lymphatic temperament, was confined in July, 1847. Previous to her accouchement, she was troubled with chronic aphtha, red canker, or with that condition of the system which is well known as "sore mouth attendant on pregnancy and lactation." Nothing unusual occurred at the time of delivery. No considerable loss of blood was sustained. As in similar cases there was a remission of diarrhœa and sore mouth for a few days after accouchement, giving rise to a hope that, being relieved from the condition of pregnancy, she would recover the powers of digestion and the assimilation of nutriment, so as to enable the system to sustain the calls upon it consequent to lactation; but in the course of ten or twelve days after accouchement, the sore mouth and diarrhœa returned with increased violence, producing great debility. The secretion of milk was copious; her pulse 120; the tongue flabby; there were frequent copious dejections of yellowish water; the face and extremities bloated, &c. Fearing the worst results for my patient, I advised the immediate removal of the child from the breasts of the mother to those of a wet nurse, at the same time informing the parents that, on the recovery of the mother, she could at pleasure reapply the child to the breasts, and have a full supply of milk, and be enabled to perform all the duties and functions of a mother for an indefinite period of time. The child was given in charge of a wet nurse, the milk gradually disappeared, and the patient recovered under the use of tonic remedies and a generous diet. Between two and three months after this, the mother called on me, having the appearance of restored health, and inquired if she might now take her child home with a hope of realising my former assurances that she would be able to reproduce her milk. I assured her there was no doubt in relation to such a result, and her ability for the future to nurse the child. She took the child, applied it to the breasts, and in the course of two weeks had a good supply of milk. I met her some nine months after, when she informed me she was happy in the enjoyment of good health, and, to use her words, she "had as good a breast of milk as if she had never dried it up."—*Amer. Jour. of Med. Sci.*

DIFFERENTIAL DIAGNOSIS OF THE DIFFERENT KINDS OF GENERAL PARALYSIS, BY THE AID OF GALVANISM LOCALLY APPLIED.

By M. Brierre de Boismont.

The author thinks that there exist two species of general paralysis, which differ completely in their nature and their seat. The first species of these progressive paralytic cases, without alienation of mind, exhibits as its essential character, a weakening, a diminution, and an abolition of irritability, more marked in proportion to the greater duration of the disease. This alteration may begin in a muscle, or in a limb, generally in the inferior extremities; then it attacks, successively, all parts, and reaches the tongue. In many cases, the autopsy, made with the greatest care, has revealed no lesion in the brain or the spinal cord, in spite of the long duration of the disease. M. de Boismont cites the case of a lady in whom first the left upper extremity, then the lower, and, successively, those of the other side, lost their power. The fingers were contracted, and it became difficult for her to hold objects; walking was effected only incompletely. The paralysis reached the tongue, and the patient pronounced, with slowness and hesitation, the words suggested by her mind. Sensibility was preserved, the intelligence was unimpaired; the disease lasted more than a year. The digestive functions were well performed; the urine and the fæces were under the patient's control. The electrical apparatus produced no contraction in the lower limbs. The tibialis anticus, the peronæi and the flexors, remained immoveable under the influence of the current. This phenomenon was remarked in a less marked degree in the muscles of the superior limbs; the muscles of the trunk were feebly contracted. To this case another is added, of a patient who died under the care of M. Andral, with all the symptoms of general paralysis, without mental aberration, which had lasted for more than a year. In this case, irritability was completely annihilated, although he could still execute some movements. Consciousness remained unimpaired to the end. The autopsy, made with care under the superintendence of M. Andral, revealed no alteration; and a microscopical examination, made by M. Lebert, exhibited only a fatty deposition in some of the muscles of the thigh. The muscular fibre of the muscles of the leg, in which irritability was extinguished, showed no alteration. It was interesting to contrast these results with those furnished by the examination of the general progressive paralysis of the insane. M. Boismont and M. Duchenne accordingly instituted experiments upon three paralytic insane patients, who were paralytic in different degrees. The first had only an intermittent stammering; the second was at the second period, but considerably emaciated; the third, who had been paralytic for several years, stood with difficulty, and was no longer able to answer questions. In all three, irritability existed in a marked degree. These experiments were repeated at the Bicêtre, and the patients were selected indiscriminately, among the most advanced cases, the most aged, and those who had kept their beds for several months. Irritability was ascertained to exist in the six cases examined, two of whom had arrived at a great degree of emaciation, and even of atrophy, especially in the inferior extremities. Almost all these patients passed their fæces and urine under them. It may, therefore, be advanced, as a constant circumstance, that in cases of general paralysis with mental alienation, there is preservation of irritability. M. de Boismont remarks, that, with regard to the seat of general paralysis, it is impossible to admit that it can always be localized in the nervous centres. There are cases of this disease which depend upon the spinal cord; others, upon the great sympathetic. There are some which are *perispherical*, and several which are not connected with any appreciable lesion of the nervous centres; and there are a certain number of cases which depend upon disease of the brain.—*London Jour. of Med.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MARCH 3, 1852.

OPHTHALMIA IN THE IRISH WORKHOUSES.

Nothing contributes more effectually to the settlement of disputed questions as to medical practice, than records of results made by persons not interested in the defence of doubtful methods. A man writes a long "paper," or perhaps a goodly pamphlet, possibly even a portly volume, to prove the certainty of the success which follows his "treatment" of some disease, and puts in evidence an overwhelming number of "cases" to establish the truth of his views; but in process of time, other men give their version of the result, and so the matter ends, About a year and a half ago, all Europe was gladdened by the pleasing intelligence that thenceforth the scourge of Irish pauperism, ophthalmia, had been arrested in its onward course; and that, like the Egyptian ophthalmia of old, its occurrence was to be but matter of history, in consequence of the unparalleled success of new and potent remedies. It now, however, appears that this somewhat sanguine view was premature, for we learn from official sources that in one union at least "99 are found totally blind, 134 blind of one eye, 80 under treatment, 9 about to lose both eyes, 6 to lose one eye, and 6 others are in great danger," and all notwithstanding the "methods of cure" which had proved so successful. Thus does the envious tell-tale Time betray the real state of the case; and thus is the country warned of the truth of the old adage, that "prevention is better than cure;" and the sooner the Poor-law Commissioners see it the better. Cure there is none for such a state of things: the only resource is to prevent its occurrence. But there lies the difficulty. This very ophthalmia suggests the question of questions—What is to be done with pauper children? The aged and infirm may be provided for without much stretch of ingenuity, or even much expense, and the sooner the able-bodied are left to their own resources the better; but the children, what are we to do with them, so that they become not blind or crippled? We put the question without any intention to attempt answering it ourselves, in order that those who are bound to do so should seek a solution. The members of the medical profession have called loudly for an opportunity to display their abilities as hygienic reformers, and now that they have it they must make good their promises. A very different report touching this matter must be laid before Parliament in 1853. We do not say this with any desire to throw blame on any one, much less to indulge in sinister predictions. We notice the matter to remind our official brethren that this is *one* of the great difficulties.

A CHAPTER ON HOMŒOPATHY.

In Ireland here we seem to view this episode in medical history more philosophically than our neighbours, perhaps because experience has taught us that human nature is not so perfect as others suppose. We perhaps see in it, too, the means by which another evil may be cured or corrected which far more endangers the character of the medical profession and obstructs the progress of medical science. Whatever tends to check the public appetite for drugs must be accepted as a benefit, however mischievous it may be in other respects. We have always said, we never minced the matter, that Hahnemann was a knave, an accomplished Dousterswivel; and we have always maintained that his medical disciples are, without exception, worthy of their master; but they are making a valuable experiment with impunity which honest men could not attempt. They are teaching us how far disease may be allowed to proceed unchecked without affecting the bills of mortality, for it amounts to that: they give no medicine whatever. This at a time when the practice of an honourable profession is every day degenerating into a vulgar and dishonest trade by the adoption of an opposite course is no small advantage. In fact, we shall presently discover the numerical results of the two methods of man-slaying, omission and commission, and ascertain whether the undertaker owes more to the homœopath than to the allopath. We are alluding to the two extremes, absolute denial of all medicine and poisonous drugging; we point at the one who sees his patient die before his face sooner than spoil his trade, and at the other who risks his life to swell the bill. What the result may be some may easily guess: we back the allopath against the homœopath in the contest. But be this as it may, one thing is clear, that honest men will have less cause to complain of the man of the small globules than of him of the large. The one puts him out and takes his place, the other puts him out and "calls in" a rival; the one corrupts not our profession, the other cannot live without doing so. Here, however, is the text which suggests these comments. The petition, the petitioners, and the petitioned, we leave to our readers:—

> The presentation of a monster petition to the superintending body of a university, praying them to concuss the consciences of its professors in the honest discharge of one of their most responsible duties, is an unprecedented event in the history of medicine in Britain, which deserves to be recorded in some more approachable quarter than the inaccessible records of a burgh magistracy. Therefore, as the petition has been printed and circulated, and thus becomes a legitimate object of criticism, we shall take leave to acquaint the reader with its contents, as well as its authors.
>
> It is well known that last year the Medical Faculty of the University of Edinburgh found it necessary to remit for farther examination a candidate for the degree of Doctor of Medicine, whose principles of practice appeared to them unsound and dangerous, and who also showed an imperfect acquaintance with some branches of medical learning. Instead of rejecting him at once, as the faculty were fully entitled to do, they humanely granted him an opportunity of informing himself farther on the points in which he did not satisfy them, and allowed him a new trial in good time for the year's graduation, in the event of success. But the misguided youth, preferring to be made the tool of designing men, withdrew his name from the list of candidates, and has thrown himself into the arms of the enemies of his university. Of the various devices contrived by these enemies, with a view to damage its interests, and at the same time to keep themselves in the public eye, the newest is a petition to its patrons, the Town Council of the city of Edinburgh. This petition, after recounting the particulars of the candidate's adventures, as reported in our number for October last, proceeds to charge the Medical Faculty of the University of Edinburgh with "requiring from a candidate an explicit pledge, limiting his future course and practice," being "a fundamental change," adopted "arbitrarily, and without the authority, or even the knowledge, of the Senatus, or of the patrons of the university." It represents, "that this innovation, if adhered to, will be highly injurious to the progress of science, and to the morality of students, as well as greatly detrimental to the usefulness and to the reputation of the University of Edinburgh; and that those who find themselves thus debarred from pursuing their studies in whatever direction truth seems to call them, will be driven to other, and possibly to foreign universities, or to separate and independent institutions." It then goes on to glorify the species of quackery which has found favour with the petitioners;

prays that the patrons of the university will show it countenance; requests their "intervention, in order that any undue attempts to interfere with the full liberty of the students of medicine may be prevented in future, and that the honour, independence, and distinguished reputation of the university may be preserved." And it concludes by requesting more specially that "the honourable patrons will cause the irregularity complained of to be brought under the immediate notice of the senatus of the university, or will act otherwise as to their wisdom shall seem best."

The substance of the petition may be set aside in a few words. The sapient subscribers, who have maliciously, ignorantly, or inconsiderately signed it, object to a candidate for medical honours being required to give satisfaction that he is competent to practise medicine, with credit to the school where he was educated, and with safety to her Majesty's lieges, according to the views entertained on these points by his examiners and teachers. But they have no objection—on the contrary, they have taken a world of trouble—to require, that these examiners shall, in the discharge of the most solemn and responsible of all their public duties, violate their consciences and let loose upon society a set of men whom they honestly regard as either infatuated or designing, and in either capacity alike dangerous to the well-being of the community.

Looking at the matter in the point of view most favourable to the petitioners, and least favourable to the Medical Faculty, it is plain that, if the patrons of the university entertain the prayer of the petition, they will have to decide whether there is to be a concussing of the consciences of one or two possible young men, who will be thought by all but the petitioners to be in the wrong, and to whom, by their own showing, it is open to go elsewhere for what they want: or of twelve indubitable professors, who are believed by the world in general to be in the right, and who cannot evade a duty—at all times disagreeable—except, indeed, by the resignation of office, which it is possible that the patrons of the university will look upon as not a very desirable alternative. And as to the special and very unusual mode here chosen for guiding the judgment of the patrons, it is equally plain that they will have to choose between the opinions of 3337 labourers and bricklayers, carters and ploughmen, sailors and tailors, masons and quarrymen, weavers, bakers, joiners, shoemakers, policemen, &c. &c., and peers—whose names we find appended to this petition—and the sentiments of thousands of the educated classes of the community, and even in the medical profession alone, who would come forward in aid of the Medical Faculty, were the patrons entitled by law to interfere, and inclined to settle the question on the arbitrement chosen by the petitioners—that is, by the public voice.

But who are the petitioners? Eight peers, three members of the Commons, not being peers, eight generals, five admirals, a sprinkling of baronets, an Irish bishop and 170 clergy, chiefly of the English Church; a less proportion of the other educated classes of society, and a multitude of the merest labouring population; some of them so low in the scale of society that they can with difficulty write their names, or spell their designations. The peers are, the Earls of Wilton, Airlie, and Erne; Viscount Newport; Barons Kinnaird, Colville, Lindsay, and Gray. The members of the House of Commons, besides Lord Newport, are Lord Robert Grosvenor, Allan Elliot Lockart, and Charles Powell Loftie. The only bishop is the occupant of the see of Down and Connor. The generals are, Lieutenant-Generals Birch, Brook, Doveton, Greenstreet, Hawker, Herbert; and Major-Generals Simpson and Willshire. The admirals are, Rere-Admirals Cator, Gambier, Henderson, Hole, and Trowbridge. In this list of twenty-six individuals, constituting the *Dii majores* among the patrons of homœopathy in the three kingdoms—for England, Scotland, and Ireland have all been ransacked for subscriptions—we are not aware of any one remarkably known for wisdom, or possessed of any other qualification entitling him to dictate to others on a question of conscientious conduct in a profession of which they are all profoundly ignorant. As for the peerage, we confess ourselves to be agreeably surprised that it is so scantily represented; and as to the number of the clergy, we feel no surprise at all. Long before the invention of any English noun ending in *opathy*, England had constantly enjoyed the singular distinction among nations of possessing a genial clime for quackery. This singular privilege she greatly owes to two of her chiefest blessings—her peerage and her church. In these two orders of society, both of them alike powerful, alike opulent, and similar in some mental weaknesses, there has always existed throughout the country an atmosphere ready to propagate any delusion or imposture in physic, however gross. Whence may have arisen a connexion so startling, it is not necessary now to inquire. Sufficient for the present is the pregnant practical fact, that quack medicines, quack doctors, and quack theories, have ever found in England the readiest acceptance among its nobility and clergy. Homœopathy, therefore, like antecedent quackeries, could scarcely fail to find a peer and a churchman to back it.

A detailed analysis of the whole subscriptions is out of the question, because we have not the requisite local knowledge of the districts in England which principally supply them. But a sketch of those who constitute the great mass of petitioners north of the Tweed, will satisfy most readers what right these people have to obtrude their advice in such a matter. In the town of Selkirk, a dissenting clergyman heads a congregation, consisting of the town-clerk, a weaver, a dresser, a pressman, a slubber, a joiner, a mill-wright, a shoemaker, four cabinet-makers, and two tailors. In the adjacent parish of Ashkirk, the Free Church minister leads a flock of one stocking-maker, one joiner, one steward, a farmer and his two sons, two farm-servants, two labourers, and two millers. Not far off, in the same county, a farmer is followed by his gardener, two shepherds, six hinds, and two ploughmen; and at Ashkirk Mill, the miller and his men themselves contribute four sturdy signatures On the other side of the Forth, the whole gardeners in the grounds of Camperdown, seven in number, give their support to the cause. And in the same county, the stone quarries of Lochee, under the guidance of an aboriginal, who graduated last year at Edinburgh by successfully hiding his homœopathic talent, have supplied the heavy-handed autographs of three carters, four quarrymen, and fifteen masons.

In Edinburgh itself, 560 individuals have been prevailed on to sign the petition. Probably sixty of these, or seventy at the most, belong to the educated classes of the community. The remainder consists mainly of all sorts of handicraftsmen; among whom cabinet-makers, confectioners and carters; porters, printers, and painters; smiths, spirit-dealers, and shoemakers; bakers and bookbinders; labourers, grocers; joiners, masons, and tailors, are the most conspicuous—accounting, in fact, for at least 240 subscriptions. We must not omit to add, nine policemen, seven sailors, and three soldiers of the garrison. Preëminent above all tradesmen are the tailors, who alone number forty-six; and one sheet contains thirteen of them in a row, who seem to have signed as they sat on their board, and to have then smoothed down the sheet with their goose. At one place a builder is followed by no less than twenty of his masons. Hard work some of the poor fellows must have had to put down their symbols, and indicate their calling. One styles himself a "pinafortrte-maker." Alexander Murdoch is a "coach-bulder, Soutth clark streat;" Andrew Oliver is a "cabnit-maker;" and William Wilmore, a "jewller," might improve the orthography of a brother in trade—Thomas Jackson, "gewler," London. John Vickory, who designates himself "gentleman," appears to have dined before signing. Another, after vainly endeavouring to identify himself by a few desperate hieroglyphics, has been enabled by some fair hand to describe himself as "servant, George-square."

Among the educated classes of Edinburgh, are particularly distinguished four advocates, six clergymen of the dissenting communions, three accountants, five military men, six esquires of some place, chiefly temporary residenters, the Rector of the High School, the Auditor of the Court of Session, and eleven medical men, of whom eight may possibly be engaged in practice, two are retired practitioners, and one, who signs himself an "intending M.D.," was, to our certain knowledge, in the same predicament at least eleven years ago. We wish our limits would allow us to analyze the whole of this flaming catalogue. The result would surprise the reader. But for brevity's sake we must confine ourselves to the two most important denominations—the lawyers and the medical practitioners.

As for the four advocates, whose profession may seem, in such a matter, to give their opinion more weight than that of others, they possibly deserve little mercy at our hands for putting their honoured title to such mean uses; but, having more consideration for one or two of them than they have had for themselves, we shall simply say—what the fact entitles, and their interference calls on, us to do—that it is not the position of any of them at the bar which has warranted them to give the colour of a legal sanction to these proceed-

ings by appending their signatures and designations; and that, if the petitioners have no better authority for the lawfulness of the measures which they desire the patrons of the university to attempt towards the Medical Faculty, we apprehend the faculty may safely regard the question proposed to be raised as not yet absolutely decided against them.

The eight signatures of medical practitioners are the following:—George Edward Allshorn, M.R.C.S., Edinburgh, Homœopathic Chemist; George B. Cochran, M.D.; James Lawrie, M.D.; John Rutherford Russell, M.D., Edinburgh; John F. Paisley, M.D., Glasgow; James Russell, M.D., F.R.C.S.Edin.; George Easson Stewart, M.D., Edinburgh; Dionysius Wielobycki, M D., Edinburgh. These, for aught we positively know, may be all engaged in medical practice. One of them, however, we believe never to have been so engaged; two we never heard of before; two others do not even appear in the Edinburgh Post-Office Directory. Of the remainder, one is only remarkable for being second editor of a periodical print called *The British Journal of Homœopathy*, another is remarkable in no respect whatsoever; and the last is an expatriated Pole, who, with his brother, was educated for four years by the Medical Faculty of Edinburgh, and exempted from all university fees—a small kindness, for which both of them have expressed their great gratitude in the only way in their power, by signing this gagging petition. We miss the signature of the Coryphæus of Scotch homœopathy. Possibly he foresaw that a request to coerce twelve professors, if refused by the patrons, might be disagreeably suggestive of a plea and necessity to concuss the remaining thirteenth. Enough, we presume, has been said to illustrate the way of getting up a petition in favour of homœopathy. A few homœopathic practitioners signify their wishes to a few dupes, who have been their patients, in the learned professions and other educated classes, no matter what may be their credit in society; and straightway they come forth with a petition weighing four pounds, measuring sixty yards, and signed by a few thousand people, as insignificant, and as devoid of all weight and influence as their own infinitesimal globules and dilutions.

Much has been lately alleged of the number of Edinburgh graduates who are supposed to have been converted to the creed, or to have put on the mask, of homœopathy. We give them as they appear in this petition:—Francis Black, Clifton; John Blyth, Dublin; Samuel Brown, Portobello; George B. Cochrane, Edinburgh; William Cryer, Bradford; John Drysdale, Liverpool; James Devonport, Clapham; R. Ellis Dudgeon, London; Richard Frith, Newcross, Kent; James M. Gully, Malvern; Claudius B. Ker, Cheltenham; David C. Laurie, Brighton; Henry R. Madden, Brighton; James L. Marsden, Malvern; Charles Ransford, York; George Rogers, London; James Russell, Edinburgh; John R. Russell, Edinburgh; George E. Stewart, Edinburgh; George Strong, Ross, Hereford; William Traill, Belfast; Dionysius Wielobycki, Edinburgh; Severinus Wielobycki, London; W. Wright, Birkenhead; Neville Wood, London.

In the English Medical Directory, fourteen others are put down as homœopathic practitioners. We are also aware of the existence of one or two more; but we have to do here only with those who have given their countenance to the monster petition. Much has been said more particularly of the number of last year's Edinburgh graduates who are homœopathists; and six or seven is the number specified by the only individual who has committed his name to the statement. In this petition we find only one; who is that very individual, and a principal touter for the petitioners.—*Edin. Monthly Journal.*

PAYMENT FOR MEDICAL SERVICES.

The following is a gratifying piece of intelligence: the payment of Metropolitan Hospital Physicians and Surgeons by more legitimate and unequivocal means than usual is an improvement, and the payment of them by any means is still better. Our provincial brethren may well complain of our city officials making a bad precedent by their working without pay, and others may deplore the annual unseemly squabbles which the present system entails, but there it ends. The cure, however, for all this is "progressing," as they say in Yankee land. Hospitals once were worth something more than the paltry dividend of pupil money; they gave character, now it is otherwise:—

In the *Lancet* is mentioned the gratifying fact that the governors of the Royal Free Hospital had determined "that in consideration of the laborious and indefatigable exertions of the medical officers, one hundred guineas be presented to each of the physicians and surgeons of the hospital, and that for the future they shall receive each one hundred guineas per annum." This is a most important move in the right direction. It suggests to me to bring under your notice a subject which, for its importance, well merits your earnest attention, and the public ought to be enlightened upon it. I mean the entire non-payment of the assistant-physicians and assistant-surgeons of several of the large hospitals of this metropolis. The duties, as you know, of those gentlemen are very arduous, and yield not in importance to those of their seniors, and are even more binding as to attendance; consequently all other engagements must give way to this one duty, and often at a pecuniary sacrifice. That a body of talented and highly-educated men should be found ready and willing at all hours to bestow their time and intellect within the walls of an hospital, without any of the world's rewards, might well excite surprise, if we knew not the vast amount of unseen charity daily and hourly bestowed by the medical profession. But men ought not to be expected, in a country like ours, with a redundant, struggling, and active middle-class population, to pursue for years a course of unrewarded practical charity. The majority of the public believe that *all* the medical officers of *all* the hospitals are paid officials; and even many of the governors and subscribers are under the same impression, and many have looked rather incredulous on being told to the contrary. That the ruling powers of those establishments, consisting chiefly of men knowing well the value of time and labour, should continue to receive the benefits arising from so large a sacrifice of both, is an anomaly difficult to explain. I have been told that they uphold the practice of this injustice by alleging that the funds over which they, for the time being, preside, could not be so bestowed. I know not whether this point has ever been fairly settled; at all events we see that, from the lowest grade of porter up to an aristocratic house-governor, are all well, some liberally, paid; and upon what principle the practice is not carried out with those of the medical staff, who derive emolument from no other source, I cannot understand. We see, nevertheless, in many cases, a most lavish expenditure of those very funds in external decoration and alterations in the buildings, having no reference either to increased accommodation, the comfort, or more speedy restoration of the patients; but often to indulge the whims of a building-committee, and enrich the builder and architect. It is also alleged, that the prospective advantages to the assistants are great. But before these are realised, death may, as it has in several cases, remove from this sphere the hard-worked assistant; his services alike unrewarded, unrecognized, and soon to be forgotten. Is this a fair state of things? Is it what the benevolent donors meant? I think not. I believe that if the case were properly represented, many persons holding the doctrine that "it is better to be just, before they are generous," would willingly so apportion their gifts, as to provide a fund, from the interest of which a proper remuneration could be given to the at present hard-worked and unpaid assistant-physicians and surgeons; and this without encroaching upon the purely charitable funds of the hospitals.—*Letter in Lancet.*

CORRESPONDENCE.

THE GORT UNION.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I find by your last impression that Dr. Nolan of Gort has again attempted to justify the course he has thought proper to pursue in reference to the working of the Medical Charities Act in that union; and that with that view, he not only denies the accuracy of the report which appeared on the subject in the Medical Press of the 21st ult., but that he actually charges your correspondent with "misrepresentations and misstatements" generally; and adds, that he has "cushioned" those parts of the discussion which might tell to *his* advantage with the readers of the Press.

If the fact of his having alluded to the additional duties of "attending bridewells and vaccinating" (which had been alluded to by others as well as by him), can un-damage him with his professional brethren, I have no objection that he should have the benefit of that "important point;" but certain it is that he can lay claim to no other defence of the interests of the profession (as far as I know or could learn) during the entire discussion, which, be it remembered, your correspondent did not profess to give in full. Had he done

so, and had you published it, it would have occupied your entire space, to the exclusion of all other matter. He, however, gave a strictly correct (Dr. Nolan's assertion to the contrary notwithstanding), though brief, account of *the argument adduced in justification of fixing the salary at so low a figure as £50 per annum*,* and that was—"That Dr. Nolan, having for the last twelve months attended ten electoral divisions (half the union) for £50 per annum—having never applied for an increase of salary—in fact, having never murmured or complained that his salary was too small, it was presumed he was content; and that being the case, what right would the board have to give a man more than what he asked; and if one medical man was content to attend half the union for £50 per annum, why should not the other half of the union be attended for the same?"

Such was the argument not alone on the first day of the discussion, but on every day since that the subject was before the board.

I now repeat, that Dr. Nolan being present on that (first) day, did not (at all events in the hearing of the speakers) utter a single syllable in reply to that argument. If he protested against the reduction of his salary when it was originally reduced from £91 5s to £50, as he stated in his first letter to you he did, why did he not say so when the contrary was asserted in his presence? Why did he allow an able and clever disputant to say in his hearing (in order to strengthen his argument and gain his point) that he never complained of £50 being too small a salary for the onerous duties to be discharged by him, and permit him to lay it down as the staple of his argument, if such was not the fact? But he says he "*did object*," and adds, "I have the satisfaction to know that there was present on the occasion an officer of the union of high character and veracity who heard my objection: it is possible my words may not have reached the ears of your correspondent."

Most certainly no such words reached the ears of your correspondent, although he was anxiously, but in vain, looking out for them. He, however, heard the complaints (after the discussion was over) of two as respectable officers as there are connected with the union, who expressed their surprise at the *studied* silence of their medical officer on the occasion; and one of them remarked to your correspondent—"One would suppose that he was afraid to open his lips:" and I would be very much mistaken if both one and the other of those officers would not be ready to come forward to repeat that observation at any time, if necessary.

I do not wish to say—by mentioning this incident—that Dr. Nolan did not tell the truth, when he says "he did object," nor that his observation was not heard by *an* officer of the union (*my* maxim being *not* to charge any man with a misstatement until it is so proved). What I wish to convey is this, that his objection was not heard by the speakers; and that, if made at all, it was made in so low a voice as neither to be heard nor noticed by the parties engaged in the discussion, and consequently of no value.

With regard to that paragraph in his letter which would certainly do justice to any special pleader of a nisi prius court, and in which he says—"My workhouse salary was *never reduced;* my workhouse and fever hospital salaries were *never united;* the motion of the guardians to reduce my salaries was *never defeated*, except by the Poor-law Commissioners refusal to sanction the reduction proposed; and on *no occasion* that the reduction of my salaries was under discussion was there a guardian present bearing the initials of D. J. H." I have only to observe, that of the presence or absence of "D. J. H.," or of the part taken by him on the occasion in question, it is not my intention to say another word, consoling myself with the reflection that he did but his duty, and that perhaps there is not another officer connected with the union who would think it his convenience to forget that he did so, except M. D. Nolan himself.

I must, however, claim your indulgence while I revert to the remainder of his *italicized* denials. He says his "workhouse salary was *never reduced*." I never said it was. But I said, on the occasion of a second attempt being made to reduce his salaries (those of the dispensary and fever hospital were previously reduced from £182 10s., to £100; consequently making this the *second* attempt) his fever hospital and workhouse salaries were included in one item, or *united* for the purpose of reducing them, and that the attempt *was defeated*. But he says "they were never united." I have before me at this moment the schedule made out by the clerk of the union for the board, on the occasion in question, and Dr. Nolan's name appears in it as follows:—

Names of Officers.	Appointments.	Present Salary.	Proposed Salary.
M.D. Nolan, M.D.	Dispensary,	£50	£40
M.D. Nolan, M.D.	Workhouse and Fever Hospital,	125	100

To be reduced from £175 to £140 by those very gentlemen who, as appears from Dr. Nolan's defence of them, are anxious to pay for every duty in regard to itself.

That scale was forwarded to the Commissioners, who wrote back to know the grounds upon which the board proposed to make those reductions before they would sanction them. A very able and explanatory report on the state of the union, showing cause for these reductions, was drawn up by the originators of the motion, and submitted to the board for adoption, as a reply to the query of the Commissioners. That report *was never adopted*, and consequently *never forwarded* to the Commissioners. Does Dr. Nolan pretend *not* to know to whom he is indebted for that fact?

I trust I have now shown the fallacy of the foregoing *italicized* denials. Indeed I had hoped that Dr. Nolan would have appreciated my forbearance in not being thus circumstantial in my former communications, and that instead of complaining of the obscurity of my diction, he would have felt obliged to me for not having entered into particulars which cannot redound, in a professional point of view, to his credit, although it may earn for him the esteem of poor-law guardians.

I never entered on a task that gave me greater pain, but I had a duty to perform, and his last letter left me no alternative. I would have willingly permitted him to enjoy the benefit of his fulsome flattery of a board of guardians, whom he once gloried in being instrumental in dismissing from office, even though that adulation was intended to damage your correspondent, with the "equivocal" initials to his name, in the eyes of those guardians; but I could not permit even him to designate what I, anxious for the welfare and independence of the medical profession, felt it my duty to do, "a misrepresentation and misstatement of facts," without at all events placing those facts in a clearer light than I have hitherto done before the profession; and leaving the profession to judge now between us, and assuring you that I shall not again trouble you on this subject, unless new matter be introduced, I remain, with many thanks, your obedient servant,

D. J. H.*

Kinvara, February 21, 1852.

[The above letter arrived too late for insertion in our last Number.—Sub-Ed.]

We have rather reluctantly devoted more space to this controversy than our subscribers may desire; but having somewhat inadvertently been the cause of its protraction, we could not in justice to either party cut it short. The subject is one of importance, and may perhaps be as well handled in this way as by editorial comment, which we always refrain from where "doctors disagree." Without expressing any opinion whatever respecting the matter at issue here, we may venture to say that, however essential to the general welfare the adoption of certain principles may be, in the present unsettled state of medical affairs individuals cannot be expected to assert them so firmly as they should on other occasions.

Appointment.—Mr. Toynbee has been elected Consulting Aural Surgeon to the Asylum for the Deaf and Dumb in London

* Since this discussion has occurred, the Loughrea board, acting on the precedent therein established by their neighbours of Gort, fixed the salaries of *their* medical officers at £60, instead of £80 (contemplated); and the Ballinasloe guardians, following both examples, reduced the £100, originally agreed upon, to £60 also!

* As these initials appear to be unintelligible to some parties, I refer them to you in the first instance for their meaning, and to Dr. Nolan of Gort in the next place, who, I am sure, will give all the necessary information on the subject to all parties concerned.

ON THE GASTRIC JUICE.

By Dr. H. Bence Jones, F.R.S., &c.

The action of gastric juice is promoted, first, by temperrature; for, at an ordinary temperature, say from 54 to 60 degrees, the temperature of this [lecture] room, no solution takes place. I have the contents of a stomach, which have been here for many hours, and probably there is not now a particle more in solution than when the contents were first removed; the temperature of the room has been sufficiently low to check all further action, and it must be raised to 96 degrees for a further solution to take place. The next great agent is motion. During the time of digestion a certain motion is, without doubt, constantly taking place in the stomach; but digestion may take place without any such contraction or gentle rubbing as one may suppose the stomach to be undergoing. This is proved by the fact that food will digest when placed in perforated balls which allow the mixture of the food with the gastric juice. Thirdly, salts are of importance in the process of digestion. Common salt, without doubt, promotes the secretion of acid by its irritation and by its chemical action on the mucous membrane of the stomach. If very much common salt, however, is taken, the process of digestion appears to be retarded. So also with other salts. It is probable that even calomel has this property of stimulating the mucous membrane of the stomach, and thus, at times, of aiding the digestive process. Another great agent in promoting the action of the gastric juice is, the removal of substances as soon as they are dissolved. As soon as the substances are dissolved they are enabled to escape, some of them by being absorbed into the veins, and some of them by passing out through the pylorus. That some of these soluble matters are constantly being removed from the stomach by the veins is proved by tying the pylorus, and finding that in the case (for instance) of a stomach filled with milk, the watery part of the milk will be taken up from the parietes of the stomach by the veins, whereby the casein is left and is much more slowly dissolved, it is certain that the solution is always going on, that a part of the contents of the stomach is always being dissolved, while the process of digestion is proceed ng. Lastly, it has been shown by the experiments of German physiologists, that atmospheric air is not at all necessary to aid digestion. If the contents of a stomach be placed in a perfectly air-tight vessel, and exposed to a proper temperature, digestion will take place.

We come, then, to the conclusion that the ferment in the saliva is the substance which acts chiefly upon the most important non nitrogenous constituent of our food—namely, starch; and that the ferment in the gastric juice acts chiefly upon the albuminous or nitrogenous constituents. Agents that stop fermentation stop digestion; for example, strong acids, alkalies, heat, alcohol. The stomach ferment differs from the saliva-ferment, in losing its action when heated, or when treated with strong acid or alcohol; also by its necessary union with an acid. The acid determines the mode of action and regulates it. If carbonate of potash or soda is added in excess, a totally different action of the ferment ensues, decomposition begins. Slightly altered ferment, like slightly altered yeast, may set up lactic or butyric acid fermentations, and there is reason to suppose that acetic acid fermentation may also occur.—*Braithwaite.*

TELEGRAPH IN ST. GEORGE'S HOSPITAL.

Messrs. Thomson and Grafton's telegraph for hospitals, prisons, and similar public institutions, has been in operation for several months, and continues to give great satisfaction. It has nothing whatever in common with the electric telegraph, is liable to none of the derangements of the latter, and costs absolutely nothing to keep it in work. It was constructed to convey orders and intelligence from the entrance hall to every ward in the hospital. In the hall there is a column about three feet high, having on its top a dial on which there are engraved a number of signals; on the walls of the wards throughout the hospital there are similar dials similarly engraved, but of a much larger size, that they may be seen from the remotest parts of the wards. On the dial in the hall there is an index or pointer, which can be moved by a handle to point to any of the signals on the dial. All the indices throughout the hospital are connected by mechanical arrangements with the index in the hall, so that when it moves all the others move precisely in the same way, If, for instance, it is desired to intimate to visitors that it is time to leave, the index in the hall is made to point to "visitors out," and not only will every index throughout the different wards of the hospital, point to the words "visitors out," which are painted in large characters on the dials, but at the same time a little hammer on the index will fall on a small bell, to draw attention to the fact that the index has moved. In this manner a vast number of signals are transmitted to the wards of the hospital, without the least noise or confusion. Formerly, when orders had to be conveyed to the nurses and attendants, the hall-porter rang a great bell in the hall, until it drew all the nurses into the corridors, and then, with Stentorian voice, shouted out the orders he had to transmit to them. It is obvious that all this noise must have been a source of discomfort to the patients. Since the adoption of the telegraph, upwards of fifty signals, amounting, for the twenty wards, to 1000 signals, are transmitted daily without the least noise, or any possibility of error. The adoption of this invention by the governors of St. George's Hospital, is an additional proof of their unceasing care for the comfort of the patients in that excellent institution.—*Lancet.*

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SUGDEN PRIZE ESSAY.

NOTICE is hereby given, that the PRESIDENT and COUNCIL of this COLLEGE offer the SUGDEN PRIZE of TWENTY GUINEAS for the best Essay that shall be presented to them on the following subject—viz.:

"HYPOCHONDRIACAL INSANITY; ITS PATHOLOGY AND TREATMENT."

The Essays, distinguished by fictitious signatures or mottoes, must be lodged at the College on or before the FIRST day of October, 1852. Each Essay to be accompanied by a sealed letter containing the name of the writer.

By order of the Council,
H. MAUNSELL, Secretary.

February 18, 1852.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

THE Examination of Candidates for the Degree of M.D. will be commenced on Monday, 12th of April, and will be continued daily, till finished; immediately after which the Graduation will take place. Those intending to become Candidates are requested to forward the necessary documents, on or before Thursday, the 1st of April, to the Professor of Medicine.

REGULATIONS.

I.—Those who possess a licence or diploma from any of the Royal Colleges of Physicians or Surgeons, or from the Apothecaries' Company, and who have been engaged for at least five years in the practice of Medicine, will be admitted to examination on producing their licence or diploma, along with satisfactory evidence of good moral character, and of having studied the classics at a university or at an academy of acknowledged reputation.

II.—Those who commenced their medical studies before October, 1840, and who have not been in practice for five years, will be admitted to examination on producing, along with their diploma, evidence of attendance at the classics, of good moral character, and of having been engaged in the study of medicine for four years, during which they must have attended, in a recognized school of medicine, the following courses of lectures:—

SIX MONTHS' COURSES.

Anatomy	Two courses.
Chemistry	One course.
Materia Medica	One course.
Surgery	One course.
Institutes of Medicine and Physiology,	One course.
Practice of Medicine	One course.
Midwifery	One course.

THREE MONTHS' COURSES.

Dissections	Two courses.
Practical Chemistry	One course.
Medical Jurisprudence	One course.
Clinical Surgery	One course.
Botany	One course.
Clinical Medicine	Two courses.

In addition to the above, Candidates must have attended for two years the wards of an hospital containing one hundred beds, and during three months a shop or dispensary for the compounding of medicines.

ANDREW FYFE, M.D.,
Professor of Medicine.

Aberdeen, February 12, 1852.

N.B.—Attempts having lately been made to impose on medical practitioners by offers to procure for them diplomas from the University and King's College of Aberdeen, without undergoing examination, it is hereby intimated that this University does not grant Degrees in Medicine unless Candidates submit to examination, conducted by the Medical Examiners, in presence of the Senatus.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Twelve months, ...	£1 5 0
Six months, ...	13 0
Three months, ...	6 6

Dr. JACOB in the chair.

ON SUDDEN DEATH IN THE PUERPERAL STATE.

By ALFRED H. MCCLINTOCK, M.D., F.R.C.S.I.,
Ex-Assistant of the Dublin Lying-in Hospital.

IT may be asserted without fear of contradiction, that the subject of death from sudden or latent causes is one which claims the deepest attention of the physician and the medical jurist. At any time the occurrence of this casualty excites painful and universal interest; but under no circumstances does it create feelings of such profound regret and dismay to all parties concerned as when it happens to a newly-delivered woman, and I question whether a man can meet with any reverse in his practice which so seriously or so unjustly prejudices his character in the estimation of the public.

Professor Meigs, in his treatise upon Obstetrics, has made the following remark:—"A woman lies down on the *lit de misère*, in order that she may give birth to a child; an attack of puerperal fever too often converts it into her bed of death. A man goes to his bed in fever under the apprehension of approaching death; he is *rescued* by the physician, but the accouchée who perishes is *lost*. There is a great difference in the sentiment connected with the cases." Now, if this observation be true of a death in childbed from obvious and progressive disease, and where the fatal result has from the first been apprehended, with how much more force does it apply to the cases of rapid and unexpected death in childbed? Occurrences of this kind happily are rare; but they are long remembered, and the panic they give rise to spreads far and wide, to the no small disparagement of the medical attendant's reputation. The records of innumerable examples of this fatal accident are to be found scattered through the periodicals and other works on medical literature; but notwithstanding their confessedly obscure nature, and the interest with which they are invested, no one, so far as I am aware, has made any attempt at collating them, or putting together in a connected, tangible form whatever fragments of information we possess on this most important subject. This, sir, constitutes the only apology I can offer for bringing the present communication under the notice of the Surgical Society. In it I shall endeavour to lay before you some at least of the causes which experience would seem to show were adequate to the sudden destruction of life in the puerperal state. In justice to the late Dr. J. Ramsbotham, it is right to state that he is the only author I can find who has given a distinct consideration to this subject. In the *Medical Repository* for 1814, he published some cursory observations "On sudden Death after Delivery," and these, with a few additions, reappeared in his "Practical Observations upon Midwifery," under the title of "Collapse after Labour." He relates four instances from his own practice of death taking place rather suddenly and without any very manifest cause soon after delivery. His remarks, however, do not tend to throw any light upon the pathology of this accident, and of the four cases which he recites one only was examined post-mortem, but without yielding any positive result.

Writers on medical jurisprudence recognize three diseases which may rapidly extinguish life and leave no morbid appearance, and these are, the simple apoplexy of Dr. Abercrombie, syncope, and the asphyxia idiopathica of M. Chevallier. No unequivocal example of the former in a puerperal patient has come to my knowledge, but of the two latter some instances may be adduced.* Idiopathic asphyxia "causes death almost instantaneously, or in a few minutes, or sometimes not for an hour and a half. The symptoms are those of fainting merely, and the only appearance in the dead body is flaccidity of the heart, with an unusual or total want of blood in its cavities." (Christison.) A very instructive example of this mortal affection has been recorded by Professor Beatty. The subject

* It may be remarked here, that some very competent authorities look upon the mortal affection described by M. Chevallier, as merely a form of syncope; and certainly very strong evidence can be adduced in support of this opinion.—(*Vide* Dr. Wright's "Pathological Researches on Suffocation and Syncope:" London, 1850.

of it was a healthy woman, aged 40, who was in the ninth month of pregnancy. She complained first of weakness and sick stomach, and almost immediately after fell back dead. He examined the body with the utmost care, and the appearances disclosed were such as directly led to the conclusion, that the cause of death was idiopathic asphyxia.

M. Chevallier's original paper on the disease was published in the first volume of the *Medico-Chirurgical Transactions*, and he there narrates an example of sudden death from this cause in the person of a lady who had given birth to twins about three hours previously. He himself conducted the post-mortem examination of the body, and from what he there found he inferred that death could only be attributed to this peculiar species of asphyxia. The same author also cites from Morgagni a case of rapid death in childbed, in which the necroscopic appearances led him to think that the woman's existence was terminated from the same cause. I am much indebted to the kindness of Mr. Barker of Cumberland-street for the permission to mention here the circumstances of two cases that came under his own observation some years ago, which serve very forcibly to illustrate this part of my subject. In each of these cases death took place quite suddenly and unexpectedly, not very many days after delivery. In both instances a coroner's inquest was held, which was the occasion of Mr. Barker's knowing anything about them. As may be well supposed, he submitted the bodies of these women to a very extensive and close scrutiny, but he failed in discovering anything to account for death, except an unusual flaccidity of the heart, with a complete absence of blood in its cavities. We may fairly conclude with him, therefore, that dissolution was the result of idiopathic asphyxia, or of some cognate syncopal affection.

These cases require no comment. The evidence they contain of death having been produced by the operation of a cause similar to that pointed out by M. Chevallier, is to my mind conclusive. That there are not more instances of the kind to be found recorded may in some measure be accounted for by the attention of observers being too exclusively directed to the abdomen in their examination of these cases post-mortem; and secondly, from the fact of the subject of M. Chevallier's paper not having been as generally known and understood as it ought to be. If the actual possibility of such a cause of death as this be admitted, there is no reason that I can see why a puerperal woman may not be the subject of it. Further, if we look upon the idiopathic asphyxia of M. Chevallier as nothing more than a variety or form of syncope, the liability of its invading a woman in childbed becomes still more apparent from the state in which her constitution is left by the act of parturition—a state of which the prominent characteristics are, an unusual proclivity to diseased action—an excitable condition of the vascular, and a morbid susceptibility of the nervous system. The shock of labour is not recovered from for many days, and during this period (the length of which necessarily varies under different circumstances) the *vis vitæ* is minus: hence any impression of a severe kind, whether affecting the mind or body, is not met by the same vital resistance as at other times. With these well-known facts before us, there need be little hesitation in our drawing the conclusion that many of the unexplained cases of sudden death in the puerperal state are to be ascribed to idiopathic asphyxia, or fatal syncope. Under the head of "Dystocia Syncopalis," Dr. Merriman gives the following history:—"An accoucheur was once attending a young woman in labour of her first child. Soon after it commenced, and during his absence, she fainted without any obvious cause. On his return the circumstance was mentioned, but as by this time she appeared perfectly recovered, no further notice was taken of it, and she was safely delivered without any other unusual symptom. On the third day after delivery she took a dose of some aperient medicine, and while in the act of relieving herself fell back and immediately expired. Probably no care would have prevented this unfortunate event. It was perhaps inexpedient to give the patient a purgative under such circumstances, a clyster would have been a more appropriate remedy, and at all events an erect posture should have been strictly forbidden."

Let us now pass on to the consideration of some of the other reputed causes of this catastrophe. It is an acknowledged law that protracted pain exhausts the principle of life, and in this way it is attempted to account for some of the anomalous cases of speedy dissolution after delivery. Touching this point, Mr. Travers has given some observations which it would be culpable to omit, coming from so high an authority. "Pain," says this author, "when amounting to a certain degree of intensity and duration, is of itself destructive. Difficult and protracted parturition is every now and then fatal from this cause; and even in cases in which neither extraordinary difficulty nor protraction was experienced, a fatal prostration has sometimes supervened which has admitted of no other explanation. The delivery has been complete, without any degree of physical injury, and not more than an ordinary quantity of blood has escaped from the vessels of the uterus. Yet the woman, in spite of the encouragement derived from the consciousness of safety to herself and infant, and of comfort from the conclusion that her sufferings were at an end, has never rallied either in strength or spirits; but after an interval, not exceeding a few hours, passed in a low and sinking state, has unexpectedly, and with little perceptible alteration, expired." (Inquiry, 2nd ed., p. 48.)

In a large proportion of the cases where this state of prostration or collapse has manifested itself, there had existed for some time previously a strong mental impression or foreboding of disaster, which presentiment, as it is termed, must have contributed materially in bringing about the fatal result. That a lengthened occupation of the mind by one dominant idea of a gloomy character should exercise a marked depressing influence upon the vital energies, is a fact of which every physician is fully aware, and of which there are innumerable examples on record. "I am well convinced of the fact," says Dr. J. Ramsbotham, "that the existence of a permanent despondency during the latter stages of pregnancy has a powerful influence in diminishing the beneficial agencies of those powers by which the necessary changes subsequent to labour are completed." (Pract. Obs., p. 119.) Mr. Travers even goes so far as to admit that among newly-delivered women "cases have undoubtedly occurred demonstrative of the fatal effect of this depressing cause;" and in illustration he relates two cases, one of which may be here quoted:—"A young lady, happily married, impressed probably by some unexpectedly fatal occurrence in the circle of her friends, entertained, from the commencement of her pregnancy, a morbid fear of death in childbirth, which, although unwarranted by any indication, became, from its continuance and increasing strength, a source of anxiety to one of her immediate and confidential relatives. She was attended by a skilful and experienced accoucheur, who was also her relation. He assured me that the labour was in all respects easy and safe, and that not a single unfavourable circumstance attended it. The child was still born and imperfect. The mother died suddenly in six hours after delivery. Every region of the body was examined with care by an eminent anatomist, and presented the appearance of health." Many other examples of a similar nature could be brought forward were it necessary for my purpose, or did time permit.* One case, however, of recent occurrence I must here relate, as it cannot be so appropriately introduced elsewhere. My best thanks are due to Dr. Gartlan of Dundalk for favouring me with the notes of this case, and also for the permission to lay them before the Society. Although the history is imperfect in so far as there was no examination of the body after death, still it is deeply interesting, and may serve to illustrate some of the pathological features of this melancholy class of cases:—"The late Mrs. K., aged 35, was confined of her first child, a live

* The uncle of Dr. Merriman, the author, once met with a very striking instance of the fatal effects of violent mental emotion in a parturient woman.

girl, on the 16th of March, 1850, after a tedious labour, which I had to terminate with the forceps. She recovered well, and after nursing for about four months, again conceived. Towards the end of her pregnancy she became full of apprehensions and fears for the result of her illness. She expected her accouchement in May, and about the middle of that month her anxiety and alarm so much increased as to require my paying her a morning and evening call, though in every other respect her health was perfectly good. On the evening of the 26th she felt more than usually uneasy and nervous, and early the following morning she awoke from a sound sleep, in pain, and after a very brief illness gave birth to a large and healthy girl. In three quarters of an hour after the expulsion of the child, she had a gush of about eight ounces of blood, whereupon I immediately removed the placenta which was lying in the upper part of the vagina. She then seemed as well and as free from all uneasiness or hæmorrhage as any patient could be, and continued so for about an hour, when she reiterated her forebodings that "something bad might still happen." In about half an hour from this she complained of pains like after-pains, and felt getting weak, so that I gave her some sherry and water, and at her own request a little brandy. Being apprehensive of hæmorrhage, I made a most careful examination, and satisfied myself there was no bleeding outwardly, nor into the cavity of the uterus, which was perfectly contracted. This examination I repeated several times subsequently. In spite of an opiate the spasmodic pains persisted, and the abdomen began rapidly to swell, accompanied with oppression of the breathing. I then applied a turpentine stupe to the belly, administered an enema, and gave a stimulating carminative draught, containing ether, laudanum, and aromatic spirits of ammonia. No improvement followed this treatment; on the contrary, the tympanitic distension of the abdomen had proceeded to such an extent that the patient exclaimed she would burst unless relieved. This induced me to send to my house for the long rectum tube. At this period Dr. Brunker gave his valuable help in the case, and we introduced the tube, and repeated the stimulants, but all to no purpose, as she was visibly sinking, the act of respiration being seriously impeded by the enormous bulk of the tympanitic abdomen. She expired six hours after delivery, and four from the first sensation of pain and distension." Such is Dr. G.'s history of this case; he has appended a few observations which I think it well to read. "I am fully convinced that hæmorrhage could have had nothing to do with this lady's death, as there was none externally, and both Dr. Brunker and myself repeatedly ascertained that the uterus was well contracted, thus showing there was none internally. She was a very fat person, of a nervous leucophlegmatic habit, she occasionally had complained of some pain in her left side, but never evinced any symptom of heart disease. During the menstrual periods, she had always been affected with great gaseous distension of the abdomen. The most remarkable feature, however, in her history was the strong presentiment she entertained for some time before her labour that she would not survive it. The mother of this lady, I may remark, died rather suddenly two or three days after her birth; and the knowledge of this fact very much fostered, if it did not actually give rise to, the long train of dark anticipations which possessed her mind for so many weeks before the occurrence of labour." It is sufficiently plain, I think, that the mere loss of blood in this case was not *per se* sufficient to destroy life, as the labour was rapid and easy. After a protracted and difficult labour, it is surprising how small an amount of hæmorrhage will occasionally prove fatal; in illustration of which I would beg leave to narrate the facts of a case which was communicated to me within the last few days. It occurred to Dr. Cuppaidge of Castlerea, who obligingly favoured me with its history. It is as follows:—"In the beginning of last month I was sent for one morning at ten o'clock a.m. to see Mrs. C., a farmer's wife, who was the mother of five children, and of rather delicate constitution. Her last labour had been very tedious, and was terminated by instrumental assistance, the forceps I believe. On my arrival I learned that she had been in strong labour for three days and nights. She seemed much exhausted and was perspiring freely, with a feeble rapid pulse. The pains were frequent and violent, the fœtal head was pretty low in the pelvis. After waiting some time, and seeing that the child made no advance, I applied the forceps, and extracted it with ease, but not in time to save its life. The placenta came away in a very few minutes, and I put on the binder tightly. In about a quarter of an hour, observing her to yawn and appear restless, I examined if there was any discharge, and put my hand over the uterus. It felt rather relaxed, and on making pressure it contracted, expelling a small quantity of blood. By this she seemed improved, but in about twenty minutes began again to sigh, and yawn, and toss her arms about, which made me grasp the uterus more forcibly, whereby a few coagula were dislodged. Symptoms of prostration, with extreme restlessness, dejection of countenance, and rapid intermitting pulse, now began to develop themselves, and though I gave her abundance of burnt whiskey—the only stimulant procurable—she continued to sink, and expired an hour and a half from the time of delivery. I can safely say the whole amount of hæmorrhage in this case did not exceed what I have repeatedly seen to occur in other patients, without producing the slightest symptom of weakness or syncope."

About the year 1808, Le Gallois, in the course of some experiments upon animals, observed in three different cases air to penetrate into the vena cava from the uterine veins, and that this was followed by instantaneous death. His son, writing twenty-one years afterwards—viz., 1829, after citing these experiments, asks this question: In many of the cases of sudden death after delivery, might not this event have been caused by the entrance of air into the circulating system through the uterine vessels? We find Ollivier repeating the same suggestive query in 1833, in the article "Air" of the *Dictionnaire de Médecine*. Since then, the advance of obstetric knowledge has placed nearly beyond a doubt the possibility of such an occurrence, and thus added one other to the manifold causes of death in the puerperal state. To Dr. Rose Cormack belongs the praise of having elucidated this very obscure subject; and of his instructive essay I have largely availed myself in the subjoined remarks. His experiments and reasoning, together with subsequent observations, justify our drawing the following conclusions—1st, that the admission of a certain quantity of air into the current of the circulation is capable of destroying life almost instantaneously—a fact, indeed, which the records of surgical practice fully corroborates; 2ndly, that the possibility of air occasionally finding an entrance into the vascular system through the uterine vessels, seems highly probable; and 3rdly, that in some few instances of sudden death soon after delivery, the only cause for the catastrophe which a minute inspection of the body could discover, was the existence of air-bubbles in the heart and vena cava.

It would be irrelevant to my present purpose to enter into the general question of the history and pathological effects of the presence of air in the veins. Those who are desirous of an enlarged acquaintance with this interesting topic, I would beg leave to refer to an essay by the late Dr. John Reid, published in the same volume with his other researches. This will be found to contain a most able and comprehensive analysis of all that is known on the subject.

The mechanism, so to speak, by which the introduction of air into the uterine veins can be effected, admits of being explained in a few words. The veins of the gravid womb present four remarkable characters—namely, their extraordinary large size; their freedom of inosculation; the total absence of valves; and their termination on the internal surface of the uterus at the site of the placenta, by large open orifices. If the uterus be examined soon after delivery at the full term, the majority of these apertures will readily admit a goose quill, and some will even

allow the little finger to penetrate without laceration. During contraction of the uterus, all these openings are hermetically closed, but when it is relaxed they again become proportionately more or less patulous. From this it is manifest that the same condition of the organ which causes flooding, is exactly that which is indispensable for the ingress of air; so that the latter, when it does take place, is almost of necessity preceded or accompanied by hæmorrhage. This fact is of some value, viewed in connexion with the history and progress of those cases where it was supposed that air had gained admission into the circulation through the uterine veins after delivery; for Amussat found in his experiments upon the entrance of air into the venous system, "that the period of death was hastened considerably in those animals whose vessels had previously been depleted of part of their blood." (Reid.) But, it will naturally be asked, does the air ever gain access to the uterine cavity, for otherwise it could not possibly find its way into the vessels of the womb? This question, I am of opinion, can safely be answered in the affirmative. Confining ourselves to the simple matter of fact, it may suffice to state, that Professor Meigs assures us he noticed the expulsion of air from the uterus immediately after delivery, "a great many times." Dr. Rose Cormack has made the same observation; and I have myself remarked a similar occurrence on at least three or four different occasions. Dr. Meigs, in his Letters to his Class, minutely describes the process by which the air is drawn up into the uterus; but it is unnecessary to delay you by quoting his remarks. With these considerations before us, then, we are in a position to adopt the language of Dr. Cormack:—"I have, therefore (writes this gentleman), not only no difficulty in believing, but am constrained to admit that, should any impediment be offered, in such cases, to the free exit of air by the os uteri, it must be forced into the uterine veins, were their mouths not protected by coagula; and thence it would rapidly pass, by the current of the circulation, up the vena cava into the right auricle." *(London Journal of Medicine*, vol. ii., p. 941.)

The intensity of the symptoms when air is taken up by the uterine veins would seem, as in other cases, to depend very much on the quantity, and on the condition of the patient. Death may ensue in a few moments from the rapid distension of the right auricle with air, and its consequent inability to contract. This first danger over, she may still perish at a remoter period from asphyxia, induced by gradually augmenting pulmonary obstruction.

Dr. Cormack refers, in support of his views, to seven cases from different authentic sources, in all of which death was supposed to have been more or less directly occasioned by the passage of air through the uterine veins into the vena cava and heart. These cases, taken collectively, form a body of evidence which it is hard to refute. In six of them, the presence of air in the veins was demonstrated upon inspection of the body, and no one of these cases exhibited any other morbid lesion adequate to account for death. In all, with a single exception where there was prolonged retention and putrefaction of the after-birth, the fatal event took place within a very few hours after parturition. The symptoms which presented themselves in these cases were very various; and those most frequently observed were by no means pathognomonic. Great anxiety of countenance, embarrassed respiration, with a sense even of impending suffocation, and a weak, rapid, faltering pulse, seem to have been the prominent features of the cases where there was time for the development or observance of symptoms.

Besides the seven instances above alluded to as being adduced by Dr. Cormack, I find another recorded in the *Provincial Medical and Surgical Journal* for November 27, 1850, by Mr. Berry. The leading features of this case it may be well to give. A woman, aged 22, was delivered of her first child after a natural labour, at seven in the evening of June 17, 1850. The placenta came away in twenty minutes, unattended by any immoderate loss of blood. At half-past eight, she expressed herself comfortable, and at eleven took some gruel. At one o'clock of the same night, her husband, who lay in the room with her, became alarmed by the patient's difficult breathing and feeling of faintness, and immediately sent for her medical attendant, but before his arrival, at two o'clock, she was dead. She lived seven hours after delivery. "The cause of death could not be accounted for as there was no hæmorrhage, and apparently nothing in the condition of the patient to prognosticate such a termination. . . . . Upon opening the abdominal cavity, the uterus was seen midway between the umbilicus and pelvis, the peritoneum covering it, and the intestines healthy, but pale; the stomach contained a small quantity of fluid; liver healthy; the kidneys presented a granulated appearance, and the urine which remained in the bladder was ascertained to be, by the application of heat, slightly albuminous. Upon cutting into the uterus it was found empty, and the vessels where the placenta had been attached, patulous; the vagina contained, at its superior part, a moderately sized clot of blood; within the chest, both lungs were congested, and contained scattered tubercles within upper lobes; the heart was the size of a male heart, and apparently distended. Upon making an incision into it, a gush of air escaped, and the organ became flaccid; no blood was found in its cavities. About an ounce of serum was observed in the pericardium. The brain was healthy in every respect. No signs of decomposition existed in any part of the body." From the remarks of the writer of this case, it is plain the impression on his mind was, that the immediate cause of death could have been no other than the air in the heart. If this conclusion be denied, we are met by the question—How, then, is the woman's sudden decease to be accounted for? It is hardly possible, I think, that the granular disease of the kidneys which she appears to have had, could have brought about the fatal event. This, however, I leave for the Society to determine. One point in the case deserves some consideration before admitting it to possess any value, and it is this, the examination of the body was not made for at least fifty hours after the woman's death, which, be it remembered, took place in the month of June. Mr. Berry has expressly stated that there were no signs of decomposition present; still the fact I have mentioned diminishes in some degree, perhaps, the importance that would otherwise justly belong to the unusual circumstance of air being present in the heart. Dr. John Ramsbotham narrates a case which I am tempted to introduce here, from the resemblance in many of its features to the foregoing history, and from the presumptive evidence it affords that if special search had been made for it, air might probably have been found in the heart, and thus explained the cause of the patient's unexpected death. It was the lady's first child, and the labour was tedious, requiring the use of the forceps. "A dead child was soon produced into the world without any particular difficulty or accident, and as soon as it was born a quantity of offensive gas, with that olive coloured fluid elsewhere mentioned, escaped from the vagina. Uterine action did not seem disposed to return, and after waiting some time a separated placenta was withdrawn. After this the uterus felt well contracted, and the woman was left in a favourable state between two and three o'clock. In the evening my friend called to inform me that this poor woman had died very suddenly and unexpectedly between five and six. All he knew about the matter was, that he was called in a hurry to the poor woman, who was represented to be in a fit, but he found her dead, with her belly much swelled. Anxious to learn the cause of so melancholy an occurrence, leave was obtained to open the body, which was inspected the next morning. . . . . On dividing the parietes the intestinal canal was seen somewhat distended with gas, but the rest of the viscera were healthy. The uterus was much extended and felt flaccid; and on pressing it a quantity of fœtid gas escaped from per vaginam; after its escape the organ became still more

flaccid. On opening into its cavity there was only one small coagulum at the os uteri. The appearance of the uterus on dividing the abdominal parietes was not unlike one at the fifth or sixth month of pregnancy. I must confess (continues Dr. R.) that before the uterus was handled or opened, I suspected death to have been occasioned by internal hæmorrhage: that certainly was not the case." (op. cit., p. 122).

Now, sir, from what has preceded, it may be safely asserted, that if the possibility of death from the admission of air into the uterine veins be not established on conclusive evidence, enough has still been adduced to show the absolute importance of making special examination for its presence in all obscure cases of sudden death following parturition. In conducting this examination our attention should be chiefly directed to the heart and vena cava. If air exist in the latter, it will probably be discoverable through its coats; at all events, before cutting into it the heart should be taken out. Previously to doing this the great vessels leading to and from the organ should be tied, and then after its removal the right auricle and ventricle are to be carefully opened under water, by which process the escape of any air will at once be demonstrated.

There are strong grounds for believing, as has been already hinted, that the idiopathic asphyxia of M. Chevallier is merely another name for syncope. Discarding all preconceived opinions, and looking only to facts, we find very many examples recorded of sudden death from fainting, in which the condition of the heart was precisely similar to that described as having existed in M. Chevallier's cases. The decision of this question, however, does not affect my present object, nor the remarks which I have ventured to offer, though I admit that it is one of no small interest and importance.

I must now, sir, bring this communication to a close; on a future occasion I hope to resume the subject, and to proceed with the examination of the other causes which may suddenly destroy life in the puerperal state. So far you perceive I have been chiefly occupied with two only—viz., syncopal attacks and the entrance of air through the uterine veins. If I have succeeded in placing the detached fragments of our knowledge with respect to these in anything of a tangible or connected form, my humble endeavours will have been amply rewarded.

Dr. H. Kennedy said that although he could not speak from experience, concerning the causes of sudden death in puerperal patients, yet he might say that he had met with it in other instances, which might be considered—at least to a certain extent—as bearing upon the subject of the present communication. In phthisis, for example, he had on some occasions known sudden death to occur long after the general symptoms which might lead to that result had subsided; and upon examination of the body after death the heart was found in the same flabby or atrophied condition, as it was found in the majority of cases of sudden death connected with the puerperal state. He was at a loss to understand why the heart should not be as frequently affected with debility as the brain, lungs, and other organs of the body. For his own part, he had reason to believe that a weak acting heart was far more common than was supposed, and if the heart of a puerperal patient was in this state, it was easy to understand how sudden death might take place in the way described by Dr. McClintock. With regard to the presence of air in the heart and veins, he was inclined to suspect that it was, in every case, the result rather of secretion or exhalation than of the entrance of air through the veins of the uterus, as suggested in the communication before the Society. He had seen it in connexion with a fatty heart, and in one case the air had formed under the mucous membrane of the stomach. In two or three instances he had seen it in the heart and veins. In the case at Dundalk, mentioned by Dr. McClintock, the patient was remarkable for fatness, and if a search had been instituted, air would in all probability have been found in the heart and veins. Dr. Kennedy also observed that in many cases of fever, death had rapidly supervened during the convalescence of the patient. In his own practice he had not met with any instances where death had taken place under these circumstances; but many such were upon record; and he had seen one case where death suddenly occurred, in a patient who made an exertion, which the system was not fitted at the time to undergo, in consequence, as he supposed, of the weak action of the patient's heart.

Dr. McClintock said that Dr. Kennedy's statement appeared to him to be one of considerable value. He (Dr. H. K.) had stated that on two or three occasions he had found air in the heart and veins. The cases in which he had seen it, were not, he believed, puerperal cases, but that circumstance did not affect what he was about to say. It had been assumed by Dr. Rose Cormack, that air never, under ordinary circumstances, existed in the vena cava, as, for example, in the case of a woman who died after a rupture of the uterus or some other accident, not resulting from positive disease. Such was the assumption, and certainly it was the most probable side of the question; but it should be borne in mind, that in questions of a medical or physiological nature, nothing ought to be taken for granted; and though Dr. Cormack had assumed that air had never been found in the heart or vena cava at a post-mortem examination, yet it was easy to believe that if air had made its way into those cavities, it might readily enough escape observation. With regard to the air being a secretion, he supposed he was to understand from what Dr. Kennedy had advanced, that it was secreted before the patient's death. Now, if such were the case, it seemed reasonable to expect that some symptoms would have occurred to throw light upon the post-mortem fact; but if, on the other hand, the air was generated after death, he must look upon it as a fact of great importance, and worthy of further investigation.

Dr. Kennedy mentioned that some time since Professor R.W. Smith laid before the Pathological Society the details of a case of flabby heart, in which a quantity of air was discovered in the vena cava.

Dr. Geoghegan—Devergie has recorded more than one case in which sudden death took place where no cause capable of explaining it could be discovered, except a spontaneous evolution of air which was observed in the right cavities of the heart and vena cava. The bodies were quite free from putrefaction. With reference to the entrance of air *ab externo* into the uterine sinuses, such an occurrence was rendered probable, not alone by the fact stated by Dr. McClintock of the occasional indications of air in the maternal passages after labour, but was also borne out by analogous facts observed lately in some inquiries relative to the condition of the cerebral veins after decapitation. These latter were found loaded with air-globules, which had no doubt entered through the patulous orifices of the divided venous trunks. Now, between the condition of the inner surface of the uterus immediately after delivery, and that of a recent wound, there is (as maintained by French writers) a good deal of analogy.

MEDICAL SOCIETY OF LONDON.

Mr. Haynes Walton exhibited some calculi, containing beans, that were taken from the bladder of a man by the operation of lithotomy, by Dr. R. Mackenzie of the Royal Infirmary of Edinburgh. David S——, a labourer from the county of Kinross, aged 46, admitted under Doctor Mackenzie into the hospital, September 17, 1851, suffering from the usual symptoms of vesical calculus, which had been more or less urgent for six months previously. The lateral operation was performed on the 13th of October, and five stones were removed. The prismatic shape and uniform size of the calculi were remarked at the time as being curious; but the presence of a foreign body as a nucleus was not suspected till some days afterwards, when the stones and their nuclei having been deprived of their moisture by evaporation, it was accidentally discovered that one of them rattled. The history of the origin of the patient's symptoms was very imperfectly obtained at the

time of his admission into the hospital; but on a more strict investigation, after his recovery from the operation, the following account was obtained:—About the end of March of the present year, after a carousal with two fellow-labourers, with whom he lodged in a barn attached to his master's farm, a quarrel arose, in which he was knocked down and overpowered by his two companions. From the injuries he received, and his state of intoxication, he was rendered senseless, and while he was in this condition, the following cruel trick was perpetrated on him by his assailants:—He was stripped of his clothes, and a quantity of beans (the common field or horse-beans, used for feeding cattle) were thrust into his mouth, and into the rectum, and several were introduced into his urethra. The manner in which these found their way into the bladder is unknown; but it is probable that several were introduced, one after another, into the orifice of the urethra, and then pushed back along the canal by pressure of the fingers on the penis and perineum. On the following morning he was found in a state of insensibility, with his genitals covered with blood. His companions had made off, and have ever since escaped detection. A number of beans were vomited, and passed per anum, on the day following the assault, and during this and the subsequent day he suffered great pain in voiding his urine, which was mixed with blood, and contained several fragments of broken beans. He was confined to bed for several days, but at the end of a week he had nearly recovered from his injuries, and his urinary symptoms had considerably abated in severity.—The patient made a speedy recovery, and left the hospital in perfect health on the 27th of November, the wound having been quite healed for ten days previously to his dismissal.

Mr. Canton brought before the Fellows of the Society, a beautiful specimen of

COMPLETE OSSIFICATION OF THE RETINA AND CAPSULE OF THE LENS,

which he had removed, after death, from the eye of an elderly man. An accident had, many years previously, destroyed the sight, and the eyeball by degrees had become atrophic. Calcareous material had been deposited in the cornea at the site of the injury by which vision was lost; and the specimen was shown which demonstrated this point. Mr. Canton stated that the so-called ossification of the retina he believed to be a deposit of bone-salts exterior to the membrane, and that the retina itself underwent absorption in consequence of the pressure thereby exerted upon it. Though similar instances had been recorded, the *extent* of the deposits in the present example might be regarded as rare.

Dr. Wagstaffe read a paper

ON TOPICAL MEDICATION IN THE TREATMENT OF DISEASES OF THE PHARYNGO-LARYNGEAL MEMBRANE.

After remarking upon the value of topical medication in the treatment of many local affections of the mucous membrane, he gave a history of the introduction of the plan of treating diseases of the pharyngo-laryngeal membrane by local applications by Sir Charles Bell, in 1816, and of its adoption by many physicians, awarding to Dr. Horace Green, of New York, the merit of having furnished to the profession irrefragable proof of the harmlessness and efficacy of this therapeutical measure. But while he thus accorded to Dr. Green great praise for the energy and talent which he has displayed in the development of this important branch of practice, his experience obliged him to state, that he could not agree with the assertion made by Dr. Green, of the facility of introducing a sponge-pointed probang through the rima glottidis into the trachea, and down even to its bifurcation. After several years' experience in the use of this remedial measure, he (Dr. Wagstaffe) had arrived at the positive conclusion, that an instrument cannot be passed with facility, and without danger, below the rima glottidis. But he was equally decided in the opinion, that a practised and skilful manipulator will seldom find a case in which he will be unable, after a suitable education of the parts, to pass the sponge-armed probang into the cavity of the larynx down to the chordæ vocales. He thought that much of the opposition that existed against this valuable plan of treatment had arisen from the assertion of the ease which attends the passage of an instrument to the bifurcation of the bronchia, and also from the exaggerated claims for its almost universal efficacy and applicability. Dr. Wagstaffe then exhibited the instruments which he employs for effecting an entrance into the larynx. These, he said, varied but slightly from those used by Dr. Horace Green, and consisted of a bent spatula, fixed in a handle, slightly concave on the under surface, so as to conform somewhat to the convexity of the tongue, and a whalebone probang, variously curved to suit the different conformations of the mouth, to the end of which a small, rounded piece of fine sponge is firmly attached. By pressing the tongue firmly down, and drawing it forward from its base with the spatula, the laryngeal surface of the epiglottis may be exposed; when this organ is in view, its posterior base being insensitive to touch, it may be used as a guide for the introduction of the sponge into the larynx. Dr. Wagstaffe also exhibited an instrument for introducing powders into the larynx and trachea—the process of insufflation. He has found a combination of nitrate of silver with sugar, in the proportion of one part of the former to six of the latter, triturated to an impalpable powder, a useful application in some chronic alterations of the mucous membrane of the trachea and bronchia. He applies the crystallized nitrate of silver, dissolved in water, in strengths varying from twenty to eighty grains to the ounce. In passing the sponge into the back of the mouth, much care should be taken to avoid a contact with the pillars or the pharynx, as the moment these are touched a more or less violent retching action is produced, by which the larynx is elevated to a contact with the epiglottis, and thus the possibility of entering it is for a time entirely precluded. He observed that, in the short space of time allotted to the reading of a paper, it would be impossible to give a detailed account of the various affections in which he had found topical medication with a solution of nitrate of silver efficacious; he would therefore confine himself to a brief statement of the diseases, and the manner in which the application might, in his opinion, be employed with the greatest prospect of success. He then gave an account of the method in which he employs these topical medications, and their value, in acute and chronic catarrhal affections of the pharyngo-laryngeal membrane, and the organic alterations which result from these, as well as from acute and chronic inflammations of this organ; also of its use in those various forms of chronic laryngeal disease which have been usually spoken of as one affection, termed "clergyman's sore throat." He likewise remarked upon its use in laryngismus stridulus, hooping-cough, and true membranaceous croup.

Dr. Cotton remarked that the operation to which the paper had reference was a very important one; it would be difficult at first, but would be facile after a few attempts. He had found a spatula for pressing upon the tongue, somewhat in the form of a horse-shoe, better than the one employed by Dr. Green. By depressing the tongue with this, the epiglottis might be seen distinctly; he had seen the sponge enter the glottis. He had found the application of nitrate of silver of much use in cases of loss of voice, in hawkers, and others who called their goods; in hysterical aphonia, and in laryngeal phthisis, when the pulmonary disease was not far advanced. He saw no use in passing the sponge beyond the larynx, because when the sponge was passed into the larynx, a spasm came on and squeezed the sponge, the fluid from which trickled down the trachea. He had never passed the sponge beyond the rima glottidis, though he had seen Dr. Green pass it to the bifurcation of the trachea.

Dr. Halley mentioned a case of cut-throat in University College Hospital, in which great difficulty was experienced in passing an ordinary probang into the trachea. He had found it difficult to pass the epiglottis in a child.

Mr. Harding said that the passage of the sponge was easy enough: the idea of difficulty had arisen from the fear of spasm, consequent upon the irritation which would arise. He had been the subject of laryngeal disease, and could pass the sponge into his own larynx, with the greatest facility, at least fifty times. There was by no means the irritation produced which some had asserted, by passing the sponge into the larynx. The irritation was not distressing. He had retained the sponge for fifteen seconds at a time. He had not found the sponge pressed upon by the sides of the larynx in the manner mentioned. The passing of the sponge was easy both in adults and children; in the latter the pressure of the finger was alone sufficient. He could not believe that the instrument had been passed down to the bifurcation of the trachea. He had never succeeded in passing it beyond the larynx. There was no pain from the application of the solution of the nitrate of silver of a drachm to the ounce. He believed that the solid nitrate might be used without suffering. He deprecated its use in the early stages of hooping-cough, in which he had seen it do great injury, producing chronic irritation of the larynx of a permanent character. In acute inflammatory diseases, he thought its use was questionable.

Dr. Cotton said that the irritation differed in different persons. He had not seen dangerous spasms in his own practice; but had seen one instance in which almost fatal effects resulted from an attempt to pass the sponge violently down the larynx; and in another case severe cough and hæmoptysis followed the use of the sponge. He had employed it in about 100 cases, and in nineteen out of twenty with such benefit that the patients wished for its repetition.

Mr. Hird remarked that no one would deny the value of the application of the nitrate of silver to diseases of the mucous surfaces. He was at a loss to understand how it could do good, however, in hysterical aphonia. He had had some experience in applying this remedy to the larynx, and he could not believe that Dr. H. Green had passed the sponge to the bifurcation of the trachea; there was no necessity, in many cases, to pass it even into the larynx, for when the tongue was pulled forward and depressed, the epiglottis could be seen, and the sponge might be squeezed by means of a forceps, and the fluid would pass into the larynx. He had seen unpleasant effects from too much fluid having been used, but they soon passed off. In cases of local inflammation, he thought we should apply the nitrate before the inflammation had arrived at its climax.

Dr. Cotton had merely mentioned the fact of the remedy affording relief in hysterical aphonia, without attempting to explain it.

Mr. Dendy had not applied the solution of caustic to the larynx, but had found no difficulty in using the solid stick in cases of tonsillitis, &c., without any spoon or spatula. The nitrate of silver might do good in cases of hysterical aphonia, by acting as a powerful astringent on the relaxed mucous membrane of the larynx.

Dr. Handfield Jones said that the glosso-pharyngeal was the incident nerve to the par vagum, and thus the pharyngeal contractions were brought about when the foreign substance was in the neighbourhood of the epiglottis; and that, when such substance was in the upper aperture of the larynx, or in the rima, the stimulation of the superior laryngeal, which was incident to the recurrent nerve, induced contractions of the muscles of the larynx.

Mr. Harvey, having thanked the author of the paper, expressed his regret that no case in detail had been related. Were the local applications the only means employed in these cases? Had the author of the paper observed, in follicular disease of the throat, that there was occasionally noise in the ears, &c., from the extension of the disease to the Eustachian tube and tympanum? He had found cases like many of those alluded to in the paper, connected with cachexia, and requiring tonic treatment. When Dr. H. Green's book appeared, he (Mr. Harvey) had gone fully into its merits, and agreed with the pathological views which had been advanced by that author. He questioned, however, whether the treatment advocated would be found so generally efficacious as Dr. Green had stated.

Mr. I. B. Brown had cured a case of crowing spasm by two or three applications of the solution of the nitrate of silver to the epiglottis. He had used no medicines except aperients. The solution of the nitrate of silver should be applied in the active stage of the inflammatory sore throat; in scarlet fever it prevented the spread of the disease to the deeper tissues.

Dr. Wagstaffe, in reply, said he had been much pleased to find that no Fellow of the Society doubted the possibility of performing the operation which he had recommended in his paper. He thought the spatula which he had exhibited, had one advantage over that of Dr. Cotton, inasmuch as the handle was out of the way. He must express his doubt of Dr. Green having passed the sponge down to the trachea; he thought it must have passed down the œsophagus—a mistake, he believed, often made. He had not seen cases like Mr. Harding's, in which the instrument was allowed to remain for any time, for almost immediately on its introduction it gave rise to an expulsive effort. Notwithstanding the fact that in Mr. Harding's case no trickling from the sponge occurred in consequence of the spasm, still this was a common result. He had found the application to the larynx useful in cases of hooping-cough, but it was most difficult in young subjects to use the remedy continuously and assiduously. With regard to its use in hysterical aphonia, he had known one instance in which it appeared to do good in that affection, after an uterine disease connected with it had been treated with success. He thought it should be used early in cases of inflammation of the mucous membranes. Constitutional treatment was also of course necessary in cases in which the local treatment was adopted. He had not seen any cases in which follicular disease of the mucous membrane of the throat had been associated with noises in the ears, or in which the glands of the Eustachian tube had become enlarged. He had used the nitrate with success in a large number of cases of true croup.—*Lancet.*

When we copy such articles as this from the London journals, our readers will of course understand that we do not vouch for their value as helps to prudent practice. There is evidently a rivalry prevailing amongst candidates for "general practice" in England which leads to dangerous interference in the treatment of disease. All deviations from the ordinary condition of parts are to be "cured," and whoever "cures" his patient with the greatest amount of physic and the most violent methods is the greatest doctor. To allow a patient to "get well" is sheer imbecility and gross ignorance of the resources of the healing art.

LONDON HOSPITAL REPORTS.

St. George's.

Hip joint Disease; Removal of the Head of the Femur.

By Mr. Cæsar Hawkins.

We had occasion to mention, but a very short time ago, that Mr. Stanley had removed the head of the femur, at St. Bartholomew's Hospital, for scrofulous disease of the hip joint in a little girl. The same operation was performed February 12, 1852, by Mr. Hawkins, on a little patient of the same sex, and about ten years of age, who had been suffering from hip-disease for the last four years. It may well be supposed that during that period the best efforts were used to obtain anchylosis, but it would appear that no favourable results were obtained.

Mr. Hawkins made a longitudinal incision over the joint, which brought the trochanter into view; and when the dissection had fully laid bare the latter process, a portion of the shaft, and the head of the bone, which was lying upon the dorsum ilii, Mr. Hawkins sawed through the shaft about one inch below the trochanter; the latter, with

the head and neck of the bone, were then easily removed. Portions of the acetabulum had now to be cut off by the common bone forceps, and a few vessels were tied. The shaft was so soft, that a few splinters were removed with the ordinary scissors.

Mr. Hawkins stated that the little emaciated patient was so situated, that even had she recovered, which event had appeared doubtful, the limb would have been completely useless. He did not consider that the removal of the head of the bone was justifiable, as long as anchylosis was likely to occur; and that the success of this case depended mainly on the state of the acetabulum. Mr. Hawkins had found that cavity, after the removal of small portions of its rim, covered with lymph, and of a pretty healthy aspect, and he hoped that a soft substance would be thrown out between the acetabulum and the shaft, to facilitate the movements of the part after recovery. He had removed some part of the shaft, in order that no obstacle should be offered to such movements. Mr. Hawkins further stated, that diseased action might nevertheless go on in the acetabulum, but the patient had certainly at present a better chance of recovery than before the operation.

In examining the parts which had been removed, it was found that a great portion of the head of the bone had been destroyed by caries; there was no actual necrosis, but the cancelli of the process had evidently undergone the changes usually effected by a slow ulcerating process. A little hæmorrhage took place after the child's removal into the ward; but this was easily arrested, and the progress was pretty favourable for a couple of days. Still it would appear that the little patient's strength had been so materially diminished by the long-continued diseased state of the hip, that she could not withstand the shock of the operation, as she died on the third day after it.

The post-mortem examination did not reveal any facts of importance, except as regards the state of the acetabulum. This cavity was filled, as had been stated by Mr. Hawkins, with a fibrinous mass, which occupied almost the whole area of the acetabulum. As this product was not firmly adhering to the bone, the finger could easily be insinuated under it. By this examination, it was found that the bottom of the cavity was in a carious condition, the centre being completely perforated, so as to allow the index-finger to impinge on the fascia lining the iliac fossa.

London.

Gunshot Wound of the Eye.

Mr. Curling has for the last few weeks had under his care a youth, aged 13, who suffers from amaurosis of the right eye, the cause of which is rather obscure. The boy was admitted January 19, 1852, and it appears that about two months before that date, whilst walking by the side of a hedge, he received in his face a charge of shots, fired, doubtless inadvertently, by a person on the other side.

The patient was not knocked down by the blow, though he bled much from the face, which was considerably ecchymosed. The parts around the left eye swelled immediately; the globe, however, remained uninjured, for the boy says that by raising the œdematous lid he could see very well. The right eye suffered a little more, some conjuctival inflammation (as it would seem) occurred, and some shots lodged in the maxillary bone, just below the inferior lid, where they can now be felt. But the inflammation did not run high; by simple means the patient was pretty well in a week, with good sight on the left side, but loss of vision on the right.

When admitted for this latter symptom, the globe of the right eye presented no abnormal appearances, *except a small clot under the conjunctiva*, which clot was being rapidly absorbed. The pupils of both eyes acted pretty equally, and though somewhat sluggish, answered the stimulus of light. When the left eye is closed the patient endeavours to obtain some vision on the right side by forcing the globe of the eye towards the inner canthus; but this effort, though it gives him a slight perception of light, does not allow him to distinguish any object. When he attempts to walk towards a given part of the ward, with the left eyelid held down, he takes the proper direction, but slants gradually away from the place which he is trying to reach. Mr. Curling ordered small doses of mercury with opium, so as to bring the patient under the influence of the metal, but this measure had no influence on the amaurosis. Blisters on the temple were also used, but no improvement took place.

St. Bartholomew's.

Amaurosis preceded by Hæmatemesis.

By Mr. Lawrence.

James P——, aged 49, was admitted into Henry VIII. ward, October 8, 1851, under the care of Mr. Lawrence, with complete amaurosis. The patient is a strong healthy-looking man, a cabinetmaker by trade; he is married and has several children. His habits were not very intemperate, but he used to drink pretty large quantities of malt liquor up to the time of the present attack. No blow or fall on the head can be remembered, but there was at the scrobiculus cordis, about a fortnight before the loss of vision, a sense of sinking and gnawing; these symptoms did not, however, prevent him from working at his trade.

After this uneasiness at the stomach had lasted about two weeks, the patient felt, at four o'clock in the morning, when getting up, a great depression of spirits; at six, after taking some coffee and an aperient pill, he felt suddenly sick, and threw up about a quarter of a pint of florid red blood. Up to this time, the sight had been extremely good, though it was sometimes much tried by reading. The man became naturally alarmed; he took some brandy and a little exercise; but at ten o'clock he threw up about the same amount of blood, but much darker than on the previous occasion, and looking very much like coffee-grounds. Some medicine was now obtained at the London Hospital; but at four o'clock in the afternoon of the same day, he vomited about three pints of clotted blood, which was so firm, that it looked, as he terms it, like pieces of liver. Much debility naturally followed this loss of blood. The patient was now attended by a surgeon, and went on for several days, throwing up now and then a little blood, and becoming very weak. Questions were carefully put to him, to avoid confusion between hæmatemesis and hæmoptysis; but it remained clear that the blood was all this time coming from the stomach.

On the sixth day after the onset of these symptoms, the patient experienced towards the evening a sensation in the left eye, as if the setting sun were surrounded by a brilliant circle. He went to bed, and on rising the next morning he was completely blind. During the whole week which preceded this sudden amaurosis, he had had a sensation in his head as if he heard a steam-engine working noisily and regularly, the sounds being louder and more distinct when his head lay on the pillow; but there was no actual cephalalgia, nor had there been any flying pains in the head.

This state of complete loss of vision lasted for about three weeks, after which the power of distinguishing light from darkness was regained. The patient now sought relief at different hospitals, among which was the Ophthalmic Institution in Moorfields. The treatment was mostly of the tonic kind; but no improvement was obtained; and when admitted under the care of Mr. Lawrence, the total blindness had lasted eleven weeks. No vomiting of blood had occurred since the attack of amaurosis, nor had the patient lost the use of any of his limbs.

On admission, the pupils were found motionless, the cæcity complete, but no visible alteration had taken place in the structures of the eyes, which presented the usual fixity so characteristic of amaurosis. Mr. Lawrence ordered good diet, steel, and blisters behind the ears. A very slight improvement was at first noticed; the general health continued very good; the man became very stout; but no actual change in the state of vision took place; and the patient was discharged six weeks after admission, in about the same condition as he was when first received into the hospital.—*Lancet.*

ORIGINAL COMMUNICATIONS.

CASE OF DIFFICULT LABOUR FROM EXTREME RIGIDITY OF THE SOFT PARTS.

By Alexander Cullenan, M.D., of Kilmacow.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—The following case, which I consider peculiarly interesting, I beg to submit for your perusal, and if you think it merits a place in the Medical Press, I will feel obliged by your publishing it.—I have the honour to be, sir, your very obedient servant, Alexander Cullenan, M.D.

Kilmacow Dispensary, February 26, 1852.

I was called on last Saturday evening, January 31st, to Knockmoyland (Thomastown Union), to attend a woman, aged 35, in her first confinement. On the previous Wednesday night, she was suddenly awoke by a pain, which ruptured the membranes, when a gush of water immediately followed, alarming her very much. From that period she had lingering pains up to six o'clock on Saturday morning, when the most *violent labour* set in; this I was led to believe continued, almost without intermission, during the day. At the time I first saw her (six p.m.), she had what I would call *raging* labour at intervals of less than two minutes: her agony was intense, and the only idea I could give of my own feelings, heartrending indeed, and those of the other beholders, is what is felt by persons witnessing the most violent puerperal convulsions, which I much apprehended would take place. I found it nearly impossible to make an examination per vaginam, in consequence of the extraordinary and perhaps unprecedented rigidity of the soft parts, both internal and external. Having at length succeeded, I found a hand in the pelvis, the lateral diameter of which could not be more than two inches, whilst that from the pubis to the sacrum was of a natural proportion. The head of the child was pressing on the upper aperture, the pressure being only slightly increased by the *action* of the uterus being more of excessive irritability than contractile force.

Under these distressing circumstances, without much hope of her being delivered even with the crotchet, I intimated to her friends my wish to have the coöperation of another medical person, and advised them to send to Waterford for my friend Dr. Mackesy, or his son Dr. J. P. Mackesy. To this they assented, and a messenger was forthwith dispatched. Finding that she passed no urine from an early hour in the morning, I relieved her with the catheter, and administered an enema, the bowels being for some time constipated. To allay the excessive irritability of the uterus, I gave forty drops of tinct. opii; but finding after the lapse of three quarters of an hour that it had no effect, I gave thirty drops more, which in a short time caused a slight remission of her sufferings. I afterwards gave twenty drops. From this time (half past eleven) until a quarter to one (when Dr. Elliott, one of the physicians to the Workhouse and Lying-in Hospital, arrived, both of the Drs. Mackesy being preëngaged), her sufferings, although very severe, were not of the agonizing character which she before endured. Dr. Elliott agreed with me that it was one of the most embarrassing, and apparently the most untoward case he ever met. In course of the night a more regular and bearing-down labour set in; but so violent were some pains that we thought a rupture of the uterus almost inevitable, and were impressed with the belief that the Cæsarian operation would be the only means of giving her a chance of her life. About eight o'clock in the morning the head of the child was about half way in the pelvis, firmly impacted, the hand and wrist immoveably jammed between it, the head, and the pubis; whilst the humerus was as immoveably fixed between the other side of the head and the sacrum, the forearm forming as it were a belt or hoop round the presenting part, and almost entirely blocking up the passage to it, owing in a great measure to the narrowness of the pelvis, as well as to the still unyielding state of the soft parts. At this crisis we determined on the expediency of delivery in some shape, and having placed her in a proper position, I commenced, under a forlorn hope, to introduce an unusually long forceps, both of us having failed in the attempt some time previously; however, by patiently manœuvring, to my great satisfaction, I succeeded in adjusting both blades, and locking them. By gradually increased exertion, of course resting occasionally, in about twenty minutes I brought down the head, preceded by the forearm, hand, and part of the humerus. After having extricated the other arm there was a slight effort at respiration in the infant; I then finished the delivery quickly as the case admitted, and divided the funis after a slight pulsation, which was there, ceased. I must here remark that the child never could pass through such a pelvis, with the other circumstances of the case, only it was rather small, and the bones of the cranium capable of much overlapping. Dr. Elliott then took charge of it, whilst I tended the mother. Owing to his (Dr. E.'s) continued and judicious exertions, animation was completely restored. It was also owing to his unremitting attention that a laceration of the perineum did not take place, in consequence of its extremely rigid state. In about half an hour regular pains commenced, which gradually brought down the placenta, the poor woman exclaiming that "she was quite well," that "she was in Heaven." When preparing to take our departure after a reasonable time, we asked to take a peep at the child, which, to our mortification, we found *killed with kindness*: the woman who had charge of it, wrapped it up in a large woollen shawl, covering the head, and placing the face against her bosom. She then rolled her cloak round herself and the child "to keep it warm," of course excluding the air, which must have caused immediate suffocation. Thus ended one of the most tragic scenes I have witnessed: from the extreme intensity of the patient's sufferings for some hours, the extraordinary rigidity of the soft parts, even the glutei muscles, more like tanned leather moulded to the shape than flesh, the narrowness of the pelvis, the curious position which the hand of the child after it was first found in the pelvis assumed, and lastly, the manner of its death.

DEATH FROM A FOREIGN BODY IN THE LEFT BRONCHUS.

I was requested to visit a child aged two years and a half. On entering the room where the child was, I was forcibly struck by its appearance as it sat before me on its mother's knee. On inquiry, I learned that about five weeks previously the child had been at play in the garden with its brother, and was carried in to the mother by a neighbour, who accidentally found him apparently suffocating; and his little brother, four years and a half old, said he had swallowed a stone. A surgeon was immediately sent for, and he was of opinion that the foreign substance was something large and rough, which had passed down the œsophagus and lacerated the throat in passing. He was led to this conclusion by finding blood on his finger, and feeling, as he said, a hard substance when he introduced it into the child's throat. Beyond this, and administering an emetic, he seems not to have done much; never examining the chest by means of percussion or auscultation. Thus seventeen days passed. The child, however, getting worse every hour, with constant and harassing fits of coughing, and wasting of the body, I was asked to visit him. As I before said, I was forcibly struck with his appearance: it was that of a person labouring under hectic fever; and whilst I sat looking at him for a few moments, before proceeding to examine the chest, as I at once surmised that it was there I should find the cause of all his symptoms, he was seized with three or four fits of very distressing cough, and my attention was arrested by a peculiar whistling or cooing sound in the chest, and which I remember once before hearing in a similar case. On stripping the chest and making percussion over it, I found a dull sound pervading a space about four inches in diameter, an inch or two below the left clavicle, and a little to the same side of the sternum;

on applying my ear directly to this part (which I did for two reasons: first, that I had forgotten my stethoscope, and secondly, that from the restless state of the child, it would have been almost impossible to apply it accurately), I heard most distinctly, not only the cooing sound before mentioned, but also a peculiar rough, rasping sound, as of air passing a foreign substance which had almost blocked up the tube. On applying my ear posteriorly, directly opposite this place, the same sounds were heard. I then examined the right lung, in which I detected puerile respiration and moist crepitus, and at once informed the parents that the substance was lodged just at the bifurcation of the bronchi, rather more in the left one; and from the debilitated and wasted state the child was in, my prognosis was very unfavourable. In answer to the mother's inquiry, whether anything could be done, I explained to her the possibility of recovery by having recourse to the operation of tracheotomy; that in all probability the admittance of cold air into the lungs would bring on a fit of coughing, and that the substance, whatever it was, might be expelled; if not, I would advise inverting the child, and applying percussion between the shoulders. Being urged to invert the child without this operation, I at once pointed out its danger; stating that unless a counter-opening existed, there was risk of suffocation. The father not being at home, I recommended them to wait and consult with him. I said that even before I would undertake the operation, I should wish for a second opinion, and I also warned them that it was not at all unlikely that death might ensue suddenly, should the foreign body become loosened in the bronchus, and be coughed up into the trachea or larynx.

The parents could not make up their minds to the step I recommended, and the result was, that on Sunday morning, February 8th, the father came for me in a great hurry, saying he was afraid I should not reach his house before the child was dead. Having nearly a mile to go, the result was as I had foretold: a violent fit of coughing had come on after the child had breakfasted, and the mother stated that she heard the substance come up into the throat, when the child fell back in her arms, became black in the face, and after one or two gasps for breath, *ceased to breathe*. When I arrived, life had been extinct for five or ten minutes. On examination of the trachea, the larger bronchi, and the root of both lungs, a horse-bean was found impacted within the two upper rings of the trachea, and at the root of both lungs were evident marks of *recent inflammation*; there was purulent infiltration on the left side, and a considerable quantity of pus issued from the bronchus on the right side. There was a roughness on the surface of the upper portion of the *left* bronchus.— *r. McCormack of Southampton in Lancet.*

MEDICAL TRIALS.

IMPORTANT TO DRUGGISTS.—FRAUDULENT USE OF SIR JAMES MURRAY'S NAME.

BAKER *v.* LANGMAN.

In this case Mr. Rupert Kettle of the Oxford Circuit, instructed by Mr. Pinchard, appeared for the plaintiff, and Mr. Whitehouse for the defendant, in the Wolverhampton District County Court, before Mr. Sergeant Clarke.

Mr. Kettle, in stating the plaintiff's case, said that Thomas Baker was the plaintiff, and Mr. F. Langman, who carried on the business of a chemist and druggist in this town, was the defendant; and although the action was brought to recover a very small sum of money (2*s.* 9*d.*), being the price paid to Mr. Langman for certain boxes of pills, purporting to be "Sir James Murray's Concentrated Cod-liver Oil Pills," yet the question was of very great public importance, and his Honour would infer from the fact of the plaintiff's case being entrusted to counsel that the plaintiff was the agent of other parties, who had taken these means for the purpose of endeavouring to prevent the continuance of a gross fraud upon the public, and a great injustice to that eminent chemist, Sir James Murray. Now he should satisfy his Honour from experiments of analysis (as far as the advanced state of chemical science would permit) what these pills really contained, and that they were utterly useless for the purpose (as stated in the printed advertisements) for which they were sold. He should call Sir James Murray himself, who was in attendance, to give evidence. He (Mr. Kettle) would read from a small handbill (in which the pills were wrapped up) a statement of what Mr. Langman professed to sell to the public. The handbill commenced with the words "Under Royal Patronage. Consumption Curable by the Use of Sir James Murray's Concentrated Cod-liver Oil Pills." Now, that there might be no mistake as to who the individual here referred to was, the bill went on to state—"Murray's Concentrated Fluid Magnesia having proved a great and lasting benefit to the public, has induced him to turn his attention to the concentration of Cod-liver Oil." Now, this statement would, in the first place, induce any one to suppose that it was possible to concentrate cod-liver oil as a medicine, which was most absurd, and could only delude the ignorant portion of the population of this district. But the bill went on to say, "and happily for the public he has succeeded, by a process known only to himself (the gentleman who would be called as a witness—Sir James Murray), in concentrating the whole of the medicinal properties of an ounce of the finest oil into four pills." Now, an experiment had certainly been made to show that this was impossible. Perhaps it was not necessary to go into that excessive proof, as the possibility of producing such a result was quite absurd. The bill went on to say—"which he now offers to the well-thinking public, for the cure of coughs, colds, influenza, asthmas, consumption, and all diseases of the chest and lungs." The bill then proceeded according to the usual course adopted by empirics of this kind, to quote all the eminent names of physicians in Europe in order to prove that they had used cod-liver oil, and that it could be concentrated in the way stated. In one of the bills, specific directions were given for the use of the pills. It was stated—"In consumption, two pills should be taken every four hours, with a teacupful of linseed or dandelion tea after each dose," and it was also stated that one pill might be given to a newly-born infant; the words used being—"It may be added here, that this medicine is so perfectly innocent that it may be given to an infant immediately after birth." Now, Mr. Langman had sold these pills. On one occasion he was seen personally by the plaintiff, and said that the pills were quite as efficacious as cod-liver oil, and that they were now selling a large quantity of them. Now, he should call Sir James Murray, who had succeeded in doing that with magnesia which had been done with Peruvian bark, where chemists had been able to disengage the valuable part of the plant, or of the substance, and concentrate it in a form convenient to administer as a medicine, and disengage it entirely from those matters which were rather an incumbrance to the medicinal part of the plant. He would prove that Sir James Murray had nothing to do with these pills—in fact, that he was indignant that his name should be used in such a way; and he would also prove by a practical chemist of competent skill, who had analyzed the pills purchased from Mr. Langman, what they were composed of, and that it was impossible to concentrate cod-liver oil into pills.

His Honour here said it was unnecessary, in order to sustain this action, to prove that it was impossible to introduce cod-liver oil into pills. It was sufficient to show that they were not pills prepared by Sir James Murray.

Mr. Kettle observed that he wished to show that they did not contain cod-liver oil.

His Honour replied that, for the benefit of the public, he had no objection that this should be given in evidence, but it was not necessary in order to sustain this action.

Mr. Kettle resumed—It had been found that these pills contained prussic acid in the shape of bitter oil of almonds.

His Honour—Not quite the thing for a new-born infant.

Mr. Kettle—Yes, not quite the thing certainly for a new-born infant. They also contained (as far as could be ascertained) a small quantity of liquorice, ammoniacum, and magnesia, but not the smallest portion of cod-liver oil; and these were the pills as to which Mr. Langman advertised that "None are Genuine unless signed Sir J. Murray's Cod-liver Oil Pills, on the Government Stamp, to imitate which is Felony." He would now call the witnesses in support of the case for the plaintiff.

Thomas Baker stated that on the 15th of November last, he went to Mr. Langman's shop and asked for "Sir James Murray's Cod-liver Oil Pills," when he received the box produced, for which he gave 4½*d.*; he went again on the 28th of November, and purchased two boxes; he saw Mr. Langman

on that occasion, and asked him whether the cod-liver pills were as efficacious as the cod-liver oil itself; Mr. Langman replied, "quite as much, and more palatable to take;" he (witness) said to him, "I suppose you sell a great many of them," he replied, "Oh! yes, we can't make them fast enough" (loud laughter); he bought some other boxes of the same pills on the 19th of January in the present year; he had paid 2*s*. 9*d*. altogether for the boxes he had purchased. In cross-examination by Mr. Whitehouse, witness said he had occasionally carted goods for Mr. Bailey, the chemist; he was not in his service when he purchased the pills; he had not taken any of them, but he should have done so if he had not afterwards been informed that they were not Sir James Murray's pills; had they been his pills he would have tried them on the reputation of Sir James Murray; he had seen Mr. Bailey in reference to this case since he had bought the pills; it was Mr. Gibbons, manager for Mr. Bailey, who informed him that they were not Sir James Murray's; he was not told this until after he had bought the first box; he then said, "If they are not Sir James Murray's, I'll go and see if they will try to impose upon me; he was sure he did not take any of them; from the information which he had received, he should say that they were more likely to kill a man than to cure him (the droll manner in which the witness gave utterance to this sentiment drew forth loud laughter); in point of fact, he (witness) was appointed to purchase the boxes in question; he should have taken the pills if they had been genuine; Mr. Gibbons had paid him the 2*s*. 9*d*. which he had given for them; he had not returned the pills to Mr. Langman, or tendered them at his shop; he bought the pills for Mr Gibbons.

Sir James Murray stated that he resided at Monkstown, Dublin, and was a physician and a licentiate in pharmacy and chemistry; he was also the original inventor of the process of making fluid magnesia, and Mr. Bailey was the agent for the sale of that chemical in this district, but it is still prepared under his (Sir James's) own care.

His Honour—And a remarkably good medicine it is.

Sir James Murray—He had never concentrated cod-liver oil into pills; it was impossible to do so; it was a monstrous fraud to say that it could be done; he had never given instructions to any one to use his name as the manufacturer of such pills; he would not be guilty of such a fraud and deception on the public; he had submitted these pills to analysis, and had seen them analyzed; the result of the experiments showed that they contained no cod-liver oil, but an oil which was very fatal to human life—the oil of bitter almonds, and this could be proved by any one who rubbed them in a cup in hot water, which would produce a smell that would fill that room; the pills also sent forth a garlicky kind of smell, but the prussic acid overcame all the rest when the pills were rubbed in hot water; a pennyworth of the stuff of which they were composed, could be made into a pound's worth of pills, but they would not be worth a penny still; the makers of these pills knew that they were cheating the public as much as if they were issuing forged bank notes; they could not possibly cure all the diseases mentioned in the bills, because what would cure one sort of disease (even if it were a good medicine) would not be fit to administer for the cure of other diseases; it was a monstrous calumny on him to use his name in connexion with these pills; he would never be connected with such a system of roguery and fraud and dangerous imposition. First, the prussic acid was sufficient to poison an infant, and even if did not poison the child it would choke it if it were attempted to be rammed down its throat, and that was another monstrous calumny on him to say that they were fit for children, and to issue such a placard was villanous, absurd, and monstrous; it was so villanous that he did hope the parties would be punished both for defrauding the public and injuring his name. In cross-examination, Sir James said that his magnesia was called "Carbonated Solution of Magnesia;" there was a villain who some time ago gave Mr. Griffiths a very dangerous dose in London, under the pretence that it was his (Sir James's) magnesia, and Mr. Griffiths brought an action against the blackguard who cheated and nearly poisoned him; there were a thousand villains substituting a thousand forgeries for his magnesia, but there was no villian who ever substituted anything so bad as these pills; he had read the report of the trial of the action brought by Mr. Griffiths; no doubt the report of that trial had been distributed about the country.

His Honour here intimated that this course of cross-examination was irrelevant; Sir James had stated that they were not his pills, and he (the learned Judge) thought the plaintiff was justified in recovering back the 2*s*. 9*d*.

The witness further stated, in reply to Mr. Whitehouse, that Mr. William Bailey was his agent, and he was intimate with him.

His Honour remarked, that even if Mr. Bailey had employed the plaintiff to purchase the pills in question, it was not of the slightest importance with reference to this action.

Mr. Joseph Turner, chemist, in the employ of Mr. Bailey, said he had analyzed the pills in question, and found that they did not contain the slightest quantity of cod-liver oil; they contained a quantity of oil of bitter almonds, liquorice, and gum ammoniacum; it was quite impossible in the present state of chemical science to concentrate an animal oil; an ordinary dose of cod-liver oil would be half an ounce, and he had found that if this quantity were made up into pills, it would require not less than sixty—not pills, but boluses—to contain it; he did not find the slightest quantity of cod-liver oil in these pills.

His Honour here observed that it was quite possible that Mr. Langman might have been deceived by those from whom he had purchased these pills, but he must say that there was no fraud more dangerous than that such pills should be offered to the public; he had already stated that he considered all which was necessary to be proved, in order to sustain this action, was that these pills were sold as Sir James Murray's pills,

Mr. Whitehouse was about to make some remarks in justification of Mr. Langman, when

His Honour again observed that he did not impute anything to Mr. Langman; some traveller probably came down from London, and said to Mr. Langman he had got some excellent pills; Mr. Langman received them and sold them, knowing nothing himself of the ingredients of which they were composed.

Mr. Kettle remarked that perhaps Mr. Langman would get into the witness-box and submit to a cross-examination no that point.

Mr. Whitehouse proceeded to argue that Mr. Langman was not personally liable to this action; that he was not present when the sales took place; that the pills were not sold as Sir James Murray's, but as "Sir J. Murray's," which was a mere descriptive term for the pills.

The learned Judge here said there could be no doubt that whoever issued these bills did so with the grossest fraudulent pretension, in order to induce the public to believe that they were pills prepared by Sir James Murray, and that his character was used for the purpose of giving credit to those pills in the estimation of the public.

Mr. Whitehouse was about to make some further remarks, when

His Honour intimated that he had better not say any more, as it was quite clear that the pills were utterly worthless, and were falsely described. If he went into a grocer's shop and asked for three pounds of moist sugar, and he was supplied with sand instead, had he not a right to recover back the money which he had paid?

Verdict for the plaintiff, with costs.

POOR-LAW PROCEEDINGS.

BELFAST UNION.

The Clerk read the following letter from the Commissioners in reply to a communication from the Board on the subject of medical aid to certain classes:—

"Poor-law Commission Office, Dublin, Jan. 17, 1852.

Sir,—The Commissioners have had under consideration a minute of the Board of Guardians of Belfast Union, of the 4th instant, stating that a medical officer of the Belfast Dispensary District had been noticed, by a relieving officer, that he would be required to attend upon a poor woman in her confinement, which was expected to take place in eight or ten days, and requesting the Commissioners' opinion or instructions upon the question, whether the committee of management should order the medical officers to attend all such cases of labour, ordinary as well as extraordinary.

In reference to this inquiry, I am to state that the Commissioners are of opinion that the duties of the medical officer of a dispensary district under the Medical Charities Act extend to cases of labour, when required to attend such cases by a ticket signed by a member of the dispensary committee, relieving officer, or warden, in pursuance of section 9 of the act, under which it will be the duty of the medical officer of a dispensary district to attend or afford medical advice or me-

dicine to any poor person resident in the district, to whom a ticket may be given in accordance therewith, and with the regulations which have been issued under section 12 of the act. The 7th section further provides that if any person who shall obtain a ticket for medical attendance from any relieving officer or warden, or from any member of the committee, shall, at the next or any subsequent meeting of the committee after the issue of the ticket, be declared by a majority of the members then present not to be a fit object for dispensary relief, the ticket shall be cancelled and the holder thereof disentitled to further relief.

The Commissioners are not able to give any more precise definition of the persons who will be fit objects for receiving medical relief under these provisions than that afforded by the act itself. The legislature appears to have relied on the exercise of a proper discrimination on the part of those individuals who are authorized to afford medical relief, by the issue of tickets, as above pointed out, subject only to the power of the dispensary committee, collectively, to cancel orders or tickets given to persons who may be improper objects for such relief.

The Commissioners, however, deem it right to observe, that if the course indicated in the guardians' minutes of issuing tickets in such cases—eight or ten days before the time of the labour—were adopted as a general practice by the relieving officers, or other persons authorized to issue tickets, it is to be apprehended that the time of the medical officers would be occupied to so great an extent (in cases of this kind) as materially to interfere with the due performance of their duties in affording medical relief to other classes of patients receiving tickets for medical relief, and that the indiscriminate issue of tickets for medical relief, in the cases contemplated in the guardians' minutes, would be liable to lead to abuse, and to cause charges to be brought upon the poor-rates where the parties may be able to provide themselves with the requisite attendance.

The Commissioners are informed that it has been a practice at dispensaries, heretofore existing, to afford assistance in labour cases to poor women unable otherwise to obtain it, by the employment of a midwife, the medical officer's attendance being only required in unusual or difficult cases; and in the latter case it would be competent to require his attendance by the issue of a ticket requiring him to visit the patient, and the Commissioners believe that a competent and experienced midwife being employed, this course has been found satisfactory, without engrossing so much of the time of the medical officer in attendance on this class of cases as to prevent the due performance of his duties in regard to the sick poor generally.

The Commissioners will be prepared to consider any proposition which the guardians may make for providing the assistance of a midwife for poor women in labour, who may be unable otherwise to obtain such assistance, if the guardians deem the employment of such a person necessary for the Belfast district, in addition to the officers already appointed for that district.—By order of the Commissioners,

W. Stanley."

Dr. McGee here rose and said—I wish to state distinctly, and I believe the board will bear out my statements, that the desire of this board was not to heap additional labour on the medical officers—that we had no such wish or object in view in forwarding the letter to the Commissioners to which this is a reply. I think you will recollect that our sole object was to ascertain whether or not the medical men could be compelled to attend to these cases, as, if they were obliged to perform all these duties, their other duties should necessarily be neglected—that there was a desire, on the part of the board, to relieve them of these extraordinary and unnecessary duties. Some observations on the subject have appeared in a public journal, concluding with expressions of surprise—Oh! oh! Whether the meaning of that was, that the board was acting harshly, I do not know; but to prevent any possibility of misconception on the subject, I now state distinctly that it was our desire to relieve the medical men of the labour that might be thrown on them, but which should not properly be thrown on them. It now appears that the Commissioners take somewhat the same view of the matter as we did. I am glad, therefore, that the letter has been sent, because the reply states that orders for attendance should not be given in ordinary cases. If people had taken the trouble to look into the act for themselves, the matter would be set at rest, for the words of the act are, "in cases of sickness or disease." Now, an ordinary midwifery case cannot be termed a case of disease, it is merely the performance of a natural function; and as for providing attendance in such cases, which the Commissioners seem to think has been the practice with us in Belfast, it never was the practice here; on the contrary, the only case of Cæsarian section which did occur was sent into the General Hospital, in order that the operation might be there performed. There is a lying-in hospital in Belfast, but it has only ten beds, and limits admission to married females, so that it is of no use, strictly speaking, in cases where the great proportion of applicants are unmarried persons. We have hitherto used the workhouse—parties have from time to time been taken in here in order that they might be confined—but I have no hesitation in saying that, if the duty is imposed on the medical men of attending all these cases, not six men, nor sixty men, would be sufficient to do it, unless they neglected their other dispensary duties (hear, hear). The case referred to took place within three or four days after notice had been given to the medical officer; it is the first case which has occurred under the medical relief act here; the woman was not a married person, but that makes no difference in the case; the medical officer was occupied attending upon her until two o'clock. His patients remained waiting all day; they were obliged to go away unattended, and got no medical relief till the day following. That is a state of things that we should not permit; we must make some provision to meet it, and if not we do an injury to society. As for the appointment of midwives, it would lead to great inconvenience, great expense, and, perhaps, even to some jobbery. I have now to move that a copy of the Commissioners' letter on this subject be forwarded to the dispensary committees for their information, with a request from the board that they will take the whole matter into their consideration, and report to us what provisions they would suggest for securing proper attendance on instrumental and difficult cases. I would now, before I sit down, ask Mr. Senior if it be lawful for our dispensary attendants to order into the lying-in ward—as we have a ward here for the purpose—any urgent or difficult cases where the females have no husbands.

Dr. Kidley seconded the motion proposed by Dr. McGee.

Mr. Senior—Before the motion was put from the chair, said he found in no part of the united kingdom that it was the practice for persons of this class to receive medical aid generally. In England, the experience of centuries did not show any such provisions to have been made, except, indeed, in extraordinary cases of difficulty; and if such a rule was not found necessary in that country, it should not, *a fortiori*, be adopted in this, where the poorer classes were so prone to rely on the rates for aid. Nothing could be a greater incentive to vice to hold out to females of the lowest classes than the assurance that they should all be provided for on such occasions. And as regarded the power of medical attendants to send into the workhouse cases of labour in destitute persons, he (Mr. Senior) was of opinion that it should be done only through the relieving officer. The medical attendant has power to send the person into the house only in case of contagious diseases, but he may send a notice to the relieving officer, in cases of difficult or protracted labour, to make provision for the patient.

Dr. McGee—Mr. Senior reminds me of the most important part of the cases. The cases which the Commissioners point out are the very cases where the doctor cannot give effective relief in their own houses or hovels. In instrumental cases how is it possible that he can attend? It is absolutely necessary for the preservation of human life that he be given the power of sending them to some hospital.

In reply to a question from Mr. Murney, whether nurse-tenders or midwives had not been appointed in Londonderry, Mr. Senior replied that he was not aware, as that union was not in his district; and in reply to another question from Mr. Watson, as to whether it was usual in England to appoint such officers, he said it was not usual, adding, that he should hesitate very considerably before he would venture on appointing another new set of officers.

On the suggestion of Mr. Senior, a caution was then given by the Chairman to give no tickets for medical aid to persons in cases of ordinary labour.

In the course of a rather discursive conversation that ensued, Mr. Murney referred to the application from the relieving officers for an increase of salary, in consideration of the increased duties which this act had thrown upon them, and Mr. Senior expressed himself opposed to any increase in salaries, but in favour of the appointment of a subsidiary relieving officer.

Dr. McGee mentioned the rule on which relief had been

previously given from the dispensaries—none to servants living under their employers' roofs, nor to persons being members of clubs and charitable societies, of which several existed in town, nor to persons having spirit licences, nor to persons occupying the entire of a house valued at £10 a year. Any of these which they thought useful might be adopted for the direction of the relieving officers.

Mr. Senior—No person can be relieved by our relieving officer who is able to pay for his or her medical attendance.

Some other conversation on the same subject then took place, and the board proceeded to the admission and discharge of applicants.

We copy the following highly characteristic discussion to remind our readers that guardians sometimes entertain strange views:—

TRALEE UNION.

The letter of the Commissioners, calling on the board to form five dispensary districts, instead of three, as the guardians had proposed to do, was read.

Mr. Hurly, in reply to Mr. Horsely, said that when the population was greater that it now unfortunately was, no inconvenience arose from the want of those dispensaries.

Mr. Horsely said that the taxation would only come to about 1½*d.* in the pound.

Mr. Hurly—The law was made when disease was stalking through the land. If the legislature were to consider the different state of things which now exists, they would legislate differently. As to the formation of districts, as pointed out by the Commissioners, if the guardians were consulted, their knowledge of the different localities would lead them to point out proper places, instead of going to the Listowel union, and fixing on the Causeway for a dispensary station, as the Commissioners had done.

Mr. Horsely, in reply to a guardian, said it was not he who suggested the Causeway, but the Medical Inspector, who did not, it would appear, know the precise boundary of the union at that point. He (Mr. H.) only *suggested* that there should be five divisions.

Mr. James O'Connell said he was the person who had the honour of seconding Mr. Denny's proposition, that three medical should be appointed. His opinion was unaltered that, with great respect for the legislature, a more useless piece of legislation never emanated from the British parliament as regards Ireland. Of all the wants that we had—and we have had many—the want of a doctor to go about and administer mere salts and jalap was the last that any one who knew the country would have dreamed of. It was really monstrous. It was right of course that the board should bow to the opinion of the Commissioners in most cases. It was fortunate, constituted as society is in this country, that they have a veto on the acts of guardians. But questions will arise, like the present, of permanent taxation, not a farthing of which of course the Commissioners will have to pay. If in providing for the wants of the people, we must all naturally feel more interested about them, residing amongst them as we do, than the Commissioners, we ought to make a stand against them if, upon the arbitrary principle of *sic volo sic jubeo*, they insist upon inflicting five dispensary districts on the union. It is always with regret that I differ from my friend Mr. Horsely, to whose opinions I look up to on most occasions. In conclusion, Mr. O'Connell proposed, with a view to prevent all cavil on the part of the Commissioners, that there should be four divisions of the union for the purposes of the act.

Mr. T. B. Hurly said there had been frequent and ample discussions on this subject already, and the opinion of the board had been fully recorded on the matter. Now, if the guardians were of any use, they ought to be allowed to do something. Here was a board of guardians, consisting of over forty members, gentlemen and rural guardians, intelligent, well acquainted with business, and having a knowledge of the different localities, endeavouring to do everything they could for the ratepayers and the paupers; and if all their acts were to be made a nullity of by the Commissioners—if the Commissioners were to come down despotically, like a parcel of Napoleons, by a *coup d'etat*, and deprive them of the constitutional exercise of their duties as guardians, let the Commissioners appoint paid guardians at once.

Mr. Denny said that, judging from the last paragraph of the Commissioners letter, it would be well if the board would concur in Mr. O'Connell's view of the subject. Though he agreed to a great extent with Mr. T. Hurly, that a great many of the acts of the Commissioners were in no small degree of an arbitrary nature, still for all that the Commissioners were persons appointed by the government to administer the act, and if this was an unwholesome arrangement, it was for the legislature to deal with it. Guardians should deal with the act as they found it. But to come to the matter in hand: If the guardians adhered to only three medical districts, and three medical men, the strong probability was that the Commissioners would take the matter into their own hands, and appoint those five districts they so strongly suggested in their letter. That being the case—though he still thought, in the present state of the country, that it would be more prudent to adhere to three districts, and see how that would work—he would recommend that Mr. O'Connell's view should be adopted, suggesting, in addition, in order to follow out their views, that a committee be appointed to consider the districts to be divided into four.

Mr. Talbot—It would be better to give what the doctors will cost to the poor to enable them to sow a handful of potatoes in the ground. That would be the best medicine for them.

Mr. O'Connell and Mr. Denny's proposition was then adopted, and a committee appointed.

BORRISOKANE UNION.

The following resolution was proposed by Wm. H. Head, Esq., and seconded by Thomas Goold, Esq.—"That this board is of opinion that the medical officer of the workhouse ought *not* to be a *candidate* for the situation of medical attendant to any of the dispensary districts, in consequence of the very onerous duties attached to his office."

As an amendment, the following was proposed by John S. Dwyer, Esq., and seconded by Thomas B. Stoney, Esq.—"I move the direct negative, it not being expedient or within our power to pass the resolution."

On a poll there appeared—for the resolution, 11; for the amendment, 3.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MARCH 10, 1852.

SURGICAL CURE FOR MEDICAL MALADIES.

PARTURIENT mountains they say produce muscipular abortions, and the happy delivery of our medical Parnassus, so long in lingering labour, has verified the adage: notwithstanding the superhuman exertions of the professorial muses who dwell upon it, the conception has led to the birth of but a diminutive offspring. The parturition, it is true, has been happy (although the presentation was that untoward one in which another prominent part took the place of the head), owing doubtless to the matchless skill of her of the nine who discharges the functions of Lucina. In plain words, *mons parturiens, nascitur ridiculus mus.* After six months of deliberation, negotiation, stratagems, and expedients, carried on without blush or scruple, the following is the result of the late "commencements:"—

UNIVERSITY OF DUBLIN—DIPLOMA IN SURGERY.—Mr. Samuel Gibson, M.B. Scholar, T.C.D., having been solemnly examined on two several days, by the Medical and Surgical Faculty of the University, has received the Diploma of Licentiate in Surgery.

UNIVERSITY INTELLIGENCE.—Mr. Samuel Gibson, A.B., M.B., having been solemnly examined on two several days by the Medical and Surgical Faculty of the University, has received the Diploma of Licentiate in Surgery.

We print the intelligence as it appears in a morning paper, first as an advertisement, and next as a formal announcement in triumphant capitals, and we learn that great have been the rejoicings therefore. Yet when we come to inquire more particularly we discover that the event does not present such flattering prospects as the elated Profes-

sors fondly anticipate; for it appears that this proselyte to the new faith is in nowise a profitable one; being neither more nor less than the Anatomical Professor's Assistant. How far the bait or decoy may prove effectual, time alone can tell; but as the matter stands, it is but a sorry result, after all the moving appeals to students in lecture assembled, all the newspaper puffings, and all the canvassings, promises, and entreaties expended. When the "demonstrator" of the concern is the only available victim *pour encourager les autres*, there must be sore lack of converts. But there is something in this announcement which provokes a feeling somewhat graver than that which elicits irony, a feeling of deep regret that a statement should be publicly made under such sanction so devoid of truth as this before us. We every day hear of denunciations, loud and long, of the obscurer members of our profession who disgrace their order by newspaper announcements of equivocal character, but never has it been our lot to see any so calculated to wound professional character as those which refer to this matter. Here is a public announcement conspicuously paraded in the newspapers, and obviously promulgated to lead to the belief that it emanates from official authority, yet so destitute is it of authenticity that the authors do not venture to attach a name to it. Then it asserts that this "Mr. SAMUEL GIBSON" has received the "Diploma of Licentiate in Surgery," which is a deliberate assertion of what is manifestly untrue; for be the nature of the certificate proposed to be issued what it may, it cannot be a *licence*, for the University cannot grant a licence even in Medicine, much less in Surgery. Then it asserts that there is a Medical and Surgical Faculty in the University, which is another gross misrepresentation, no such body having any existence there. In these days, we are aware, that this method of "doing business" entails no reproach, public or private—*nous avons changé tout cela*; but nevertheless we cannot refrain from alluding to the matter. For our own parts, we feel no surprise, for we have long since learned the value of caps and gowns, bands and hoods, as evidence of the wearer's truth or integrity, and we have never participated in the vulgar delusion which leads to the belief that they who live in squares and ride in coaches engross all the honour and honesty. But be all this as it may, the futility of these miserable expedients are demonstrated by the results of this same "commencement." What will our readers say when we inform them that these same Professors had not one single candidate to present to the heads of the University for the degree of M.B. on the occasion? Two were presented for that of M.D., one being no less a personage than the present President of the College of Physicians, who, by the way, has ingeniously contrived to wriggle himself in amongst these University Professors: in fact, the Medical School of the University is all but defunct, and its Professors, who have brought about this happy consummation, can find no other method of consoling themselves than pulling down the College of Surgeons along with it. We would, however, fain hope that the heads of the University will open their eyes to this monstrous state of things, and even now perceive the mischief to which the institution is exposed by this unlucky combination. It is as clear as the sun at noon-day that the interests of these medical gentlemen are not identical with those of the College at large. The object of the University is of course to provide a liberal education for all classes, the medical included: the object of the Professors is to open a back door to admit the uneducated. It is literally so. While the great gate in College-green is open to admit those in pursuit of knowledge, a back door is open in Park-street for the dunces, and these dunces are to be foisted on the surgical profession. We cannot believe that the Provost and Board will still allow themselves to be so grossly cajoled by these functionaries as they have been. The mission of the University is general, not professional, education, and we can assure them that the sooner they hand over that of medical and surgical practitioners to the Colleges of Physicians and Surgeons the better.

PAYMENT FOR MEDICAL SERVICES.

IT cannot but be gratifying to the profession to learn that Drs. WHITE and NUGENT, the Inspectors of Lunatic Asylums, uphold its character and position by their advice and interference in procuring for the medical officers employed in their department an honourable remuneration for their time and trouble. The beneficial effects of this protection were well evinced at the last meeting of the Board of Governors of the Cork District Asylum, when a salary of £430 a year, with a very superior suite of apartments, was allotted to Dr. POWER, resident physician to that institution.

MIDWIFERY DUTIES OF DISPENSARY SURGEONS.

WE have to direct the attention of our readers to the report of the proceedings of the Belfast Union respecting this matter. The views entertained there, and especially as expressed by Dr. MCGEE, are both sound and rational. Had we not better at once declare that every member of the labouring class in Ireland is under poor law care, and that both wet and dry nurses should be provided for all babes requiring such attentions. Foundling hospitals, too, should be revived, with a proviso that the "medical officers" shall look after the infants without additional charge. If guardians are so gallant as to provide thus for the ladies, they must also provide for the payment of their accoucheurs, for the imposition of such duty on the Dispensary Surgeon is absolutely out of the question. In our former allusion to this matter we meant not to reflect on this Board; on the contrary, aided as they are by such an intelligent member as Dr. MCGEE, they are, we believe, doing good service.

AUDACIOUS PIRATICAL PROCEEDINGS OF QUACKS.

THE large space devoted to the trial in which Sir JAMES MURRAY successfully establishes the illegality of the practices pursued by these pests of society, prevents us from dwelling on the subject at present. It now remains for others similarly assailed to do likewise.

CORRESPONDENCE.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In the 13th section of the Medical Charities Bill, it states that—"The medical officer of every dispensary district constituted under this act, shall, and he is hereby required to vaccinate all persons who may come to him for that purpose, subject to such regulations as may be issued by the Commissioners in that behalf, and which regulations the said Commissioners are hereby required to make and issue, &c." Are the guardians bound to contract for the supply of vaccine matter to the medical officers of each union? or will each medical officer be obliged to subscribe (out of his small salary) to the Vaccine Institution, Sackville-street, in order that he may have always at hand a constant supply of genuine infection? In my opinion the eighth section of the act solves this question. It provides as follows:—" . . . . and

shall provide such medicines and *medical appliances* as may be necessary for the medical relief of the poor in the said district, &c." Surely vaccine matter must be considered as a medical appliance in the same category as splints, bandages, surgical instruments, &c. &c.—I am your obedient servant,

March 4, 1852. A SUBSCRIBER.

In this we entirely agree. It is vain to fence with the law. Medical relief must be afforded and paid for.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Allow me to suggest to the President and Council of the Royal College of Surgeons in Ireland (through the medium of your journal) the propriety of conferring on their Licentiates and Fellows the title of Doctor in Surgery, similar to the University of France. This would add to the respectability as well as the utility of the College, it being already acknowledged to be as much a College of Physicians as Surgeons in a practical point of view, qualifying the holder of its diploma to practise medicine as fully and as freely as any M.D. or member of any College of Physicians. It behoves the Council to do something at a period like this, when we have the Queen's Colleges in existence and the University of Dublin tampering with surgery by arming their students in medicine with the title of Licentiate in Surgery, under the direction of a medical and surgical faculty, and thus in a *trivial manner encroaching* on the privileges of the Royal College of Surgeons in Ireland.—I am, sir, your obedient servant,

A LICENTIATE OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

This suggestion is worthy of serious attention, and it is, we believe, in course of careful consideration. The College of Surgeons of Ireland is to all intents and purposes a College of Medicine and Surgery, and now that other institutions have raised the free trade banner it cannot remain passive. The rights of its Fellows and Licentiates must be asserted, and in no way can this be better done than by the course here proposed.

DEEP PENETRATING WOUND OF THE CALF OF THE LEG, BY A REAPING-HOOK, FOLLOWED BY PROFUSE HÆMORRHAGE.

By E. L. HUSSEY, Surgeon to Radcliffe Infirmary, Oxford.

THIS wound was produced accidentally, by means of a reaping-hook, upon the person of Isaac Carter, aged 66, and of feeble general appearance. It is described as "on the middle of the back part of the left leg, extending in a transverse direction about two inches, penetrating deeply into the muscular substance." On Mr. Briscoe, the house-surgeon, removing the handkerchief which had been tied round the leg immediately after the infliction of the injury, a gush of arterial blood followed, and it was found that the wound extended further than the finger could reach, on the tibia and interosseous membrane, under the deep muscles.

It was clear that some deep-seated vessel of magnitude was wounded, which it was imperatively necessary to secure; and as it did not seem prudent to wait, I proceeded to search for it without sending to Mr. Hitchings, whose week of attendance it was.

A tourniquet being thrown round the thigh, and the man placed on his side, with the limb partly flexed, I made an incision about four inches long through the skin upon the inner edge of the gastrocnemius, over the course of the posterior tibial vessels, meeting the tibial extremity of the transverse wound at about a right angle, and, dividing the other tissues interposed, came at once upon the anterior tibial artery, both ends of which were seized and tied without difficulty: the distal extremity, though easily recognized, was not bleeding. The artery, as well as the nerve, was completely divided by the original injury. The clots in the wound were then turned out, and some muscular branches which seemed inclined to bleed were next tied. Profuse hæmorrhage still continued with violence, but of a dark venous character, welling up from the bottom of the wound; this, however, became lessened on removing the tourniquet. To get at the source of it I enlarged the wound upwards toward the knee, and some bleeding points were tied upon a tenaculum—an operation of great difficulty, from the patient's restlessness and the depth of the wound. One vein, larger than the rest, and apparently in close connexion with some tendinous structure, seemed to be wounded at more than one point. Ultimately, the hæmorrhage was stopped by passing three ligatures, at intervals of half an inch, under this vessel and the surrounding tissues by means of a needle in a firm handle. The wound was drawn together with strips of plaster, a compress of dry lint placed on it, and the whole secured, and even pressure maintained by a bandage round the leg; and the patient, cold and perfectly pulseless, replaced in a blanket in bed. Wine and brandy were administered freely during the operation, and on his return to bed he was supplied well with hot brandy and water.

About nine o'clock at night Mr. Hitchings saw him; he was then warm; the pulse was weak, but distinctly perceptible at the wrist. The finger placed on the dorsum of the foot distinctly recognized, for the first time, the anterior tibial artery; the posterior could not be felt. He was still as restless as ever, throwing himself about, and with difficulty kept in bed; he had twice torn the bandage off the leg, without, however, any return of hæmorrhage. The muscles could be seen acting spasmodically under the bandage. A drachm of spiritus etheris sulphurici compositus, with forty minims of vinum opii, was administered in mistura camphoræ; it was speedily vomited, when a grain and a half of opium in substance was given and retained. He continued very restless till towards three o'clock in the morning, when he went off to sleep.

On the succeeding day he seemed to have rallied a little. There was a slight watery discharge from the wound, tinged with blood. Beef tea, and brandy and water were administered, and as no urine had passed, the catheter was introduced. On the 14th, however, fatal symptoms supervened, and he died quietly, forty-eight hours after receiving the wound. On a post-mortem examination being made, it was found the ligatures had been correctly placed on the divided extremities of the posterior tibial artery. The three additional ligatures had been placed upon one of the venæ comites. The tendon of the plantaris lying immediately over the vein had interfered with the application of the ligatures. It would have been better to have divided this tendon. The extremities of the vessel were nearly an inch distant from each other, owing to the retraction of the muscles. The cause of death was evidently from the inability of the system to rally from the severe loss of blood previous to admission.

The chief point of interest in the case is, that it shows with what ease the posterior tibial artery may be exposed when necessary, in the upper part of its course, by cutting through the muscles covering it; and the unfortunate termination of the case does not seem a sufficient reason for withholding the publication of it. The operation, I venture to suggest, may be done by cutting upon the edge of the gastrocnemius, and then through the substance of the soleus, with less difficulty—as it seems more directly in the course of the vessel, which there lies at less depth—than by cutting, as proposed by Mr. Guthrie, through the belly of the gastrocnemius as well as the soleus; though that operation seems more practicable than the older mode of cutting upon the edge of the tibia, and reflecting the muscles attached to it, notwithstanding the preference given by Dr. Harrison of Dublin. This mode of operating was suggested to me some years ago by Mr. Coote. On the *dead* subject it appeared undoubtedly to be preferable, but I had not till now had an opportunity of putting it in practice on the living.—*Braithwaite's Retros.*

MODE OF EXHIBITING BALSAM OF COPAIBA.—M. Guibourt uses thirty parts of balsam to four of suphuric acid, stirred together in a glass mortar. A solid mass is the result, which is readily made into pills, and covered with sugar, or silvered, according to the taste of the patient. This process affords a good test of the purity of the balsam, as if it is adulterated with castor oil it will not solidify.—*Jour. de Chimie.*

DR. BELLINGHAM ON ANEURISM.

Lately published, 12mo, price 4s.,

OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.

By O'B. BELLINGHAM, F.R.C.S.I.,
One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chirurgical Review.*

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet.*

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences.*

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review.*

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author.*

London: John Churchill, Princes-street, Soho.
Dublin: Fannin and Co., Grafton-street.

UNIVERSITY OF ST. ANDREW'S.

NOTICE is hereby given, that the next Examination for the Degree of Doctor of Medicine will commence on Wednesday, the 5th of May. Fellows and Members of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin, of the Faculty of Physicians and Surgeons of Glasgow, and Licentiates of the London Apothecaries' Company, are eligible for examination.

Every Candidate is required to communicate by letter with Dr. Day, the Professor of Medicine, fourteen days before the period of Examination, and to present himself to the Secretary for registration on or before the 4th of May.

By order of the Senatus Academicus,
JAMES MCBEAN, A.M., Secretary.

St. Andrew's, March 4, 1852.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SUGDEN PRIZE ESSAY.

NOTICE is hereby given, that the PRESIDENT and COUNCIL of this COLLEGE offer the SUGDEN PRIZE of TWENTY GUINEAS for the best Essay that shall be presented to them on the following subject—viz.:

"HYPOCHONDRIACAL INSANITY; ITS PATHOLOGY AND TREATMENT."

The Essays, distinguished by fictitious signatures or mottoes, must be lodged at the College on or before the FIRST day of October, 1852. Each Essay to be accompanied by a sealed letter containing the name of the writer.

By order of the Council,
H. MAUNSELL, Secretary.

February 18, 1852.

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

THE ROYAL EXCHANGE ASSURANCE,

Incorporated A.D. 1720, *by Charter of George the First.*

THOMAS TROUTON, AGENT,
No. 8, WESTMORLAND-STREET, DUBLIN.

Fire and Marine Assurances on liberal terms.

Life Assurances with Bonus (which has averaged 43 *per cent.* on the Premium); or, at lower rates, without Bonus.

Moderate Premiums and a fair division of Surplus.

Age.	With Profit. £ s. d.	Age.	Without Profit. £ s. d.
20	2 0 11	20	1 17 6
30	2 11 7	30	2 7 8
40	3 6 3	40	3 1 9
50	4 11 3	50	4 5 8

Exemption by the Charter from the liabilities of Partnership.

The Security of a large Capital Stock, and the moral guarantee afforded by 131 years' experience and reputation.

The soundness of a thoroughly tested Office, with all the real improvements of modern practice.

THOMAS TROUTON, AGENT,
(Successor to Richard Purdy,)
No. 8, WESTMORLAND-STREET, DUBLIN.

Dr. JACOB in the chair.

FRACTURE OF THE SPINE—HYPERTROPHY OF THE BLADDER CAUSED BY LONG-CONTINUED DISEASE OF THE SPINAL CORD.

By Professor HARGRAVE.

(Reported by Mr. ARTHUR H. TAYLOR.)

R. D——, ætat. 36, Ringsend, sailor, admitted into the City of Dublin Hospital, under the care of Dr. Hargrave, at about ten o'clock on the morning of November 3, 1851.

About half an hour previous to his admission he had been crushed under a ten-ton boat which he had been assisting to raise, it slipped, and fell on the back of his neck whilst leaning forward, thus forcibly pressing him forwards and downwards. He was kept in this position nearly two minutes before he could be extricated. When admitted, he was in a partial state of collapse, the extremities being cold, face pallid. There was an acute angular projection posteriorly of about the ninth or tenth dorsal vertebra, evidently produced by fracture of some part of the osseous column. There was very extensive ecchymosis over the middle dorsal vertebræ, and considerable irregularity of the spinous processes, both above and below the fracture, the line or curve of this irregularity deviating to the right side. There was complete paraplegia, loss of motor and of sensitive power, retention of urine, and on drawing it off with the catheter (which had to be done throughout the whole progress of the case) he did not feel the passage of the instrument. Two o'clock: Reaction having set in, pulse 98, but rather weak, he was ordered to have

Venesectio ad ʒxij.

4th. Appears better; says he has been very much better since the bleeding; the ecchymosis has decreased.

℞ Calomelanos, gr. viii.
Pulv. opii, gr. i.
Theriac. q.s. M. ft. pil. viii. Capt. i. mane nocteque.

5th. Pulse 98, stronger; slept well during the night; more natural warmth in lower extremities; still lower in temperature than the rest of the body; says he feels better, and does not complain of any pain. The following plaster to be applied over the prominence on the back:—

Habeat emplast. belladonnæ.
Fiat venesectio ad ʒviii.

7th. Partial priapism; complains much of thirst; lower extremities warm, but not morbidly so.

Aqua hordei, lb. ii.

8th. Priapism disappeared almost entirely; pulse 108, weak; on drawing off the urine to-day, some blood was found mixed with it; the bladder was washed out with tepid water, or rather water with the intense cold removed; this was done every day whilst under treatment; both urine and fæces pass involuntary; increased thirst. Ordered effervescing draughts during the day, along with the following draughts:—

℞ Acidi gallici, gr. xv.
Mucil. gum. acaci, ʒiv.
Aquæ distillatæ, ʒiiss.
Syrupi zingiberis, ʒiv. M. Divide in haust. iii.
Capiat i. tertiis horis.

10th. Pulse stronger; feels much better; less blood in urine, and much clearer.

Rept. haust. injec. enema. terebinth.

11th. Pulse 96; urine clear; no blood in it; is now becoming ammoniacal; restless night.

12th. Good night; feels drowsy; tongue dry; countenance becoming worn and hollow; some pus and blood in the urine, which is now highly ammoniacal. Beef-tea diet.

Rept. enema. et haust. acidi gallici.

℞ Decocti matico, ʒvi.
Tr. matico, ʒiv.
Tannin, gr. xxiv. M. Divide in haust. vi.
Capiat i. ter in die.

14th. Slept none; decreased quantity of pus and blood in urine; says he feels faint; this was almost the first time that he made any serious complaint; there are two large bedsores on the back over the sacrum; his back was dressed carefully every day and washed with camphorated spirit; he has also been kept on a water-bed for the last week, but without effect; for though it gave him great

ease, yet it has not succeeded in preventing bedsores; these are now sloughing. Wine ʒii.; arrow-root.

15th. Feels weak; appetite good; less blood in urine; increased purulent deposit; he says he would like some meat. Ordered a lean chop.

16th. Sleepless night, but appears better; ate his chop with good appetite.

℞ Decoct. matico, ʒv.
Tr. matico, ʒiv.
Acidi tannici, gr. xxiv. M. In haust. sex.
Capt. unum ter die.

17th. Feels a more agreeable sensation of heat about the feet; does not feel pinching; no morbid heat; bedsores increasing; scrotum excoriated by the constant dribbling of urine and irritation of the fæces, which are continually passing involuntary; urine contains a quantity of muco-purulent matter, with some blood, but less than at first; the bladder is injected every morning and evening; bedsores to be dressed with strong solution of nit. argent. and lint.

19th. He is much the same; appetite good; pulse stronger and fuller than usual; considerable deposit in urine, which has all along and now is highly ammoniacal.

Acid. muriatici dil. gtts. v. with each injection of bladder.

20th. Considerable decrease of mucus and blood; feels much better; bedsores greatly improved by the dressing with nitrate of silver solution; it completely checked all further tendency to increase; the penis has been œdematous for the last two days, and is now very much so.

27th. From the last note he went on very much the same way; appetite remaining good; bedsores increasing a little; urine, however, becoming extremely fœtid, and containing a quantity of mucus, pus, and a little blood. Ordered to have the bladder injected twice a day with the following:—

℞ Sol. chlorid. sodæ gtts. vi.
Aquæ, ʒii.

This had a great effect in correcting the extremely fœtid smell.

29th. Sinking rapidly; pulse very weak; great flaccidity of muscles of leg; foot forcibly extended by the extensor muscles of the leg. Ordered wine ʒii.

December 1st. Two very large humid sloughs separated from the bedsores; there was some bleeding from the parts, but not much; he has a slight cough; appetite failing; feet becoming œdematous; countenance haggard and sunken; the angular prominence of the fracture appears to have diminished considerably. Wine ʒiv.

3rd. Tongue dry; pulse 108; had some vomiting yesterday; says he feels very weak.

5th. Pulse very small and weak; some cough and considerable dyspnœa. Ordered to have a mustard sinapism to the chest, and pil. scillæ co. gr. v. ter in die.

6th. Patient sank slowly, and died at about eleven p.m.

Necroscopia twenty three hours after death.—Spinal column: Fracture of the body and transverse processes of one of the last dorsal vertebra. The body of the injured vertebra was shortened, thickened, or widened out, apparently owing to the cancellated structure of which it was composed having been driven into itself, or impacted. Medulla spinalis: The cord itself was bent at an acute angle over the fractured bone, and broken across. The cauda equina was ruptured, and the marrow softened. There was effusion of blood between the cord and its theca, and between the latter and the bone. There was a formation of small pellicles of an osseous nature, six or seven in number, and somewhat larger than a pin's head but flat and thin, lying on the surface of the cord between it and its membranes. Kidneys: Left kidney perfectly healthy. Right kidney enormously enlarged, and completely disorganized in the whole of its upper portion, the only part not diseased being a small portion at its inferior extremity. The urine found in both kidneys *gave an acid reaction with litmus paper.* The bladder presented an extraordinary appearance, it was highly disorganized, being sacculated and marked on its internal surface by a number of muscular bands, somewhat analogous to the carneæ columnæ of the heart. Its parietes were very much thickened, in some places being about an inch thick. Throughout its thickened structure there were depositions of round, apparently fatty bodies. The neck of the bladder was filled with a collection of lateritious substance having the appearance of common mortar. The urine found in the *bladder* was highly alkaline or ammoniacal.

The most interesting pathological fact afforded by the post mortem examination of this case was the greatly hypertrophied condition of the muscular coat of the bladder, which seems to have commenced long prior to the accident. Such an increase of muscular structure could not have taken place in the short period of four weeks and six days, for which there was no cause or impediment in any contracted condition of the urethra, as the catheter was always passed with facility into the bladder, which was perfectly passive in its functions of expulsion, as the urine and muco-purulent secretions mixed with blood were daily removed by the catheter, whatever incontinence of urine occurred being due to an over-distended bladder, still requiring the use of the catheter to remove it and the accumulated tenacious mucus, also for the purpose of injecting deterging fluids into the bladder.

This increase of the muscular fibres of the detrusor urinæ was dependent on the chronic disease in the spinal cord close to the cauda equina, as was evidenced by the osseous deposits in its structure, and which appears to me to have existed long previous to the accident.

That I am borne out in this opinion appears to be established from a specimen of pathology I prepared some years since of a boy in whom the bodies of the dorsal vertebræ, from the third to the twelfth, were completely removed in a case of Pott's curvature; their spinous processes were united by osseous matter to preserve the spinal column in something of a normal condition; the bladder was hypertrophied in its muscular coat; the urethra was perfectly free and healthy.

Dr. Geoghegan—Dr. Hargrave's case which he (Dr. G.) had an opportunity of observing while in hospital, afforded a most interesting illustration of the reflex function of the spinal cord, as developed by Dr. Marshall Hall. From the fact that the paralysis of the lower limbs coincided with a total absence of reflex movements (on tickling, pricking, &c.), he (Dr. G.) had ventured to predict that the cauda equina would be found compressed, as now seen in the preparation. As respects reflex movements, therefore, the lower extremities were in the same predicament as if the great nervous trunks supplying the latter had been divided: thus affording a marked contrast to those instances of paralysis from injury or disease higher up in the spinal column, in which such movements are remarkably evident. The paralysis of the bladder, in the present case, seems to have depended on compression of the *nervous trunks of the cauda equina*, and not *on that of the cord*; for although the lower part of the cord being enveloped by the superior portion of the *cauda* was necessarily compressed, still the pressure was exercised at a point inferior to the origin of the nerves of the sacral plexus, and hence the interruption of the excito motory circle, on which urination depends, could not have taken place *in the cord.*

Dr. Stapleton would thank Dr. Hargrave to inform him, if the retention of urine continued up to the very close of the patient's life; or if, towards the end of his days, there was not rather a dribbling of the urine?

Dr. Hargrave replied that the catheter was used three or four times a day, not only to draw off the urine, but to enable them to introduce a cold water injection, with a view to correct its alkaline and fœtid character.

Dr. Stapleton said he must dissent altogether from Dr. Hargrave's view as to the hypertrophy being produced by disease of the spine. On more than one occasion he had seen bladders, whose coats had been greatly thickened in the space of a month or six weeks, and in those cases there

was reason to believe that the hypertrophy was in a great measure due to the change which had taken place in the character of the urine. In some instances, which had fallen under his observation, ulceration of the bladder had occurred, and in one remarkable case an opening was made into the rectum, and in another at a point where it gave rise to infiltration near the neck of the bladder. His opinion was, that the hypertrophy of the bladder in Dr. Hargrave's case, instead of being induced by disease of the spine, was the natural consequence of injury which it underwent at the time of the accident, the alkaline urine having of itself given rise to induration and thickening of the coats of the bladder.

Dr. Hargrave had seen cases where urine of an alkaline character had led to some degree of hypertrophy of the bladder, and where a mortar like discharge of the same kind as was found in the present instance lined the interior of the organ; but in no former occasion had he encountered a bladder so enormously hypertrophied as the bladder of this patient appeared to have been: and coupling this state of the bladder with the existence of the morbid products found in the spinal cord, there was, in his judgment, abundant evidence to prove that the patient must have suffered from chronic disease of the spinal marrow for at least some years before he met the accident in question.

Mr. Collis inquired of Dr. Hargrave whether any increase of temperature was observed in the paralysed limb?

Dr. Hargrave replied that no increase of temperature from the time of the man's admission into the house up to the moment of his death. Neither sensation, nor reflex action of any kind, could be detected in the paralysed limb. A somewhat remarkable symptom in the case was that on the fifth day after his admission the man was affected with priapism.

Mr. Collis mentioned that a perceptible rise of temperature took place in the limbs of a patient, who was brought into the Meath Hospital about two years ago, with his spinal column almost completely severed.

ACADEMY OF MEDICINE, PARIS.

SPONTANEOUS DEVELOPMENT OF GAS IN THE BLOOD, A CAUSE OF SUDDEN DEATH.

By M. Durand Fardel.

M. Durand Fardel read a paper before the Academy of Medicine of Paris on the spontaneous development of gas in the blood. The history of the following case, which formed the principal part of the paper, may be looked upon as a description of the disease, which, notwithstanding the writings of Morgagni, of Reyrolles, and Ollivier, is still only imperfectly known.

A lady, living at Versailles, aged 56, rather tall and fat, came to Vichy, along with her husband, who was affected with gravel. It appeared that this lady had enjoyed very good health, not having been indisposed, at least for some years back. She had ceased to menstruate about six or seven years ago, and had been subject to no hæmorrhoids nor epistaxis; did not complain of headache, nor any other disorder; her digestion seemed to go on regularly; she never suffered from deafness or loss of memory; she had a good appetite, and led a regular life; belonged to the middle class of society. She did not complain of rheumatic or gouty pains, but she sometimes complained, not of palpitations, but of a slight difficulty of breathing. Her breathing was habitually short, as frequently happens to fat people, and which she never attributed to any other cause.

This lady, being at Vichy, wished, as is the fashion, to take the baths, and obtained authority for that purpose from the physician who attended her husband. She also drank some glasses of the mineral water, but in small quantity.

July 20, 1850. She proceeded to the thermal establishment to take her second bath at four o'clock in the morning. She had been in good health in the evening, had dined as usual, and had slept well. In going to the establishment, her respiration was more difficult than usual; she had to rest herself sitting before taking the bath, and the attendant seeing her so oppressed, advised her not to take the bath for that day. At the end of half an hour she wished to get out of the bath; her maid, who had not left her, had not remarked anything particular about her. But she did not feel at ease, and when she got up from the bathing-place to change her dress, she appeared agitated, and complained of oppression; then she got out, and sunk into a chair before she could be covered with a dry sheet. Respiration had become difficult, although she made violent efforts to breathe; she had lost the power of expressing herself. In the meantime, I had been sent for at the first symptoms of the affection. Five minutes had not elapsed before I was with her. She was then dead.

I found her sitting in a chair, supported by the persons who surrounded her, still covered with her wet bathing-shift. The face had completely lost its colour; the lips slightly violet; the face not distorted or disfigured; no froth on the lips; the limbs were flaccid, and quite insensible; complete absence of pulse and sounds of the heart; pupils dilated and immoveable; conjunctiva insensible to the touch.

Although this state left no doubt of the reality of the death, I made a large opening in the median basilic vein of the right arm. There flowed immediately a little blood, not black, but violet and frothy; that is to say, accompanied by bubbles of gas, of unequal volume, which came from the vein at the same time. I remained more than a quarter of an hour making useless endeavours, tickling the uvula, applying ammonia to the nostrils, &c. During this time I did not quit the arm, examining the exit of the frothy blood, which continued to flow from time to time, under the influence of pressure applied on the forearm from below upwards. One time, a jet squirted out with some force, and lasted for five or six seconds, as if driven out by a bubble of gas, which was developed in the interior of the vessel; a slight quantity of white froth showed itself at the lips.

The autopsy was made twenty-two hours after death, the 31st of July, at three o'clock in the morning. The body presented no appearance of putrefaction; some lividity only on the depending portions of the trunk and members. The heart was very large; the right cavities distended with liquid blood, rather violet-coloured than black, syrupy, very frothy; the bubbles of gas enclosed were some (very numerous) as big as the head of a pin, others, less common, as large as peas. When pressure was applied over the course of the two venæ cavæ, the blood which flowed into the right auricle was frothy, like soap and water. The parietes of the right cavities of the heart presented a superficial violet colour; the left side was completely void of blood, and not coloured; the left ventricle was considerably hypertrophied; the orifice of the heart did not present any appreciable alteration, as also the aorta. All the abdominal venous system was distended with violet and frothy blood; also numerous bubbles of gas were found in the blood of the splenic and portal vein. The lungs filled the chest; presented a few adhesions, and some appearances of emphysema; their colour was reddish outside, but of a deeper tint internally, where it presented traces of considerable sanguineous congestion, without infiltration of blood. There was considerable frothy congestion in the more depending parts. The bronchi contained some whitish frothy mucus. The abdominal organs presented nothing more worthy of notice than a considerable sanguineous congestion of the liver, spleen, kidneys, and a remarkable congestion of the veins of the epiploon and mesentery. The epiploon was very fat; the stomach rather large, and containing about half a glass of clear colourless mucus. The intestines were not opened. The encephalon did not present the same degree of congestion as the other organs; the sinuses of the dura mater contained only a little liquid blood, not frothy. The brain and origin of the spinal marrow, examined as soon

as possible, appeared completely natural, a little injected with blood; no bubbles of gas appeared in its vessels.

We publish this case in all its details, as science possesses as yet very few cases of this kind. The observations of Morgagni, wanting in certain details, do not allow of a certain judgment. M. Reyrolles, in two cases of death by hæmorrhage, found the blood frothy in the heart and veins.

Finally, M. Ollivier of Angers, published a case (*Ann. Gen. de Méd.*, 1838) which leaves no doubt as to the existence of the disease which M. Durand Fardel observed in this case. A curious circumstance, doubtless observed before, enabled M. Durand Fardel to state the existence of gas at the moment even of death. The bleeding performed at the arm gave issue for more than a quarter of an hour to blood, which, trickling from the vein of a body deprived of life, carried with it numerous bubbles of gas.

To what cause can the origin of this gas be attributed? This is a question still undetermined, and which may be perhaps solved at some future time by the chemical analysis of the gas found in the blood. Whatever it may be, the observations of M. Durand Fardel tend to prove that it is owing to a spontaneous exhalation from the veins, caused by a spontaneous alteration of the fluid, of which we know neither the nature nor the cause.—*Presse Méd. de Bruxelles.*

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

FORMATION OF AN ARTIFICIAL ANUS.

By Mr. Adams of the London Hospital.

The patient was a lady, aged 35, the mother of children. She had for a considerable time complained of great difficulty in passing her motions. This was accomplished with pain and much straining, and she was the subject of hæmorrhoids. She was hereditarily predisposed to cancer. About a year ago, a surgeon pronounced her case one of cancer of the rectum, with ulceration. The bowels were constipated nine days, and the usual purgatives were administered, and scruple doses of calomel, without effect. Her sickness was allayed by opium and sucking ice. The rectum-tube could not be passed above four inches. Scirrhous rectum, very high up, was presumed to be the cause of the obstruction. Metallic mercury to the extent of two pounds, was given, a small quantity of which passed soon after. The operation was performed according to Mr. Luke's method. The descending colon and sigmoid flexure were undistended. In the course of a few hours, a large quantity of fluid fæces passed, and the relief was complete. She continued to progress favourably, and since the operation has been better than she had been for some years. Occasionally a small quantity of fæces pass per anum, but it is nearly all discharged by the wound; there is also occasionally a small quantity of bloody mucus passing per anum. A light truss is used to restrain the constant passage of the fæces, and there is a distinct tendency to pass them twice daily. A large quantity of the mercury passed by the wound soon after the operation, but a very considerable quantity was retained until a short time ago, and it then passed per anum. The patient was slightly salivated, apparently from the calomel, the mercury being unaltered.

TWO CASES IN WHICH THE OPERATION FOR ARTIFICIAL ANUS WAS PERFORMED.

By Mr. W. J. Clement, F.R.C.S., Shrewsbury.

Case 1.—The author visited, on the 8th of October, 1841, a married woman, aged 47, who was suffering from obstruction of the bowels of fourteen days' duration, accompanied by great distension of the abdomen, hiccough, incessant vomiting, which during the last two days had become fæcal; the countenance was anxious; the pulse small, rapid, and fluttering. It appeared that for the previous seven or eight years the patient had suffered from habitual constipation, and had required the constant use of drastic purgatives. The abdomen was tympanitic on percussion everywhere except on the right inguinal and iliac regions, where it was dull. It was evident, from the fact that several pints of fluid could be injected into the colon, that the obstruction was not in its descending portion. On the 10th, the symptoms having undergone no abatement, and the patient's state being evidently hopeless unless relief could be obtained by operation, it was proposed by the author, and performed on the same day. The patient was placed on her belly; the incision was made midway between the last rib and the crest of the ilium, extending from close to the spinal column to a line cutting the anterior superior spinous process of the ilium perpendicularly. The colon was found to be distended. It was secured by a couple of ligatures passed through its coats; and a vertical incision being made into it, a large quantity of liquid fæces escaped, together with much flatus. Immediate relief was obtained; the unfavourable symptoms ceased; the fæces were passed more or less freely through the wound, and at the end of six weeks the patient was able to walk a mile. About this time the discharge through the artificial anus became gradually less; at the end of seven weeks vomiting and colicky pains returned, but ceased after the expulsion of a mass of plum-stones, when a free exit for the fæces was again established. The patient lived for more than three years after the operation, enjoying tolerable health, and able to walk a considerable distance, and to attend to her domestic affairs. Aperient medicines were taken regularly, and the passage of fæces was pretty free. Plum-stones were passed at intervals; the total number collected was 116. The patient's health declined for some months before her death, the appetite decreasing, the strength failing, and emaciation progressing. On examination, a very complete stricture was found to exist in the transverse colon, which would not admit even the passage of a bristle. It was about a quarter of an inch in length. The coats of the bowel at this point were of a dense, white cartilaginous structure. The muscular coat of the cæcum and ascending colon was much thickened, and there was great distension of the gut behind the stricture. No traces of inflammatory action were to be found in the peritoneal cavity, with the exception of three membranous bands, which extended in a lateral direction, connecting the lower part of the ilium with the cæcum and ascending colon.

Case 2.—The driver of a mail coach, a stout muscular man, aged 43, consulted the author in January, 1847, suffering from constipation and external piles. In the month of March the constipation had become more obstinate, and the patient was obliged to give up his occupation. The symptoms were relieved by cupping on the loins, calomel, and other purgatives. On the second of April, rigors, which had occurred once during the month of March, returned, and were followed by vomiting, which continued for two or three days. Examination of the rectum showed the existence of a stricture about six inches from the anus. The attempt to pass rectum bougies of the smallest size failed. An elastic gum urethra bougie passed the obstruction, and upon withdrawing it, liquid fæces and flatus were voided. This operation caused great constitutional disturbance, rendering bloodletting, leeches, and calomel and opium, necessary. The discharge from the bowels was very slight; the vomiting recurred frequently. On the 12th of May, three small fleshy bodies, with a little feculent matter, were voided. No fæces passed from the rectum subsequently. During the remainder of the month of May the patient suffered greatly from hiccough, vomiting, and most troublesome tenesmus. On the 30th, the formation of an artificial anus was proposed, but declined by the patient. On the 18th June, feculent vomiting began, and returned on the 20th, and the patient then consented to have the operation performed. Examination of the rectum with the finger had given evidence of a morbid growth within the rectum, which was increasing in bulk. The operation was performed on the 20th June. No feculent matter having passed the rectum since the 12th of May, the abdomen was enormously distended. The incision was made on the left side, in the same direction as in the former case, but of greater extent. The bowel was secured by

ligatures, and a free incision made into it, but nothing but flatus escaped. As moderate pressure over the abdomen had no effect in causing a discharge of fæces, the patient was placed in bed on his left side. The vomiting and hiccough continued; about eight hours after the operation an immense discharge of liquid fæcal matter took place, with some abatement of the symptoms. The author gives a detailed report of the patient's state during seven days following the operation, during which there was considerable constitutional irritation, with much tenderness of abdomen, and retention of urine. The catheter was passed repeatedly, but the secretion of urine was very scanty, the fæcal discharge continuing more or less constant and copious. At the end of the week the improvement was very decided, and continued for ten days—viz., until July 8th, when acute pain in the left side of the abdomen and rigors occurred, followed by enlargement of the glands in both groins; and sloughing of the skin over the sacrum and right hip, which had begun four days after the operation, but subsequently had appeared likely to cease, began again to extend itself, in spite of the partial removal of pressure by means of the water-bed, &c. It was found, on examination, that the morbid growth occupying the rectum had increased very much, and it was evident that the difficulty attending the emptying the bladder, was caused by its pressure. A tumour projected through the sphincter ani a few days before the patient's death, which bled on being touched. The enlarged glands in both groins continued to increase in size, and the skin in the left groin began to ulcerate. Death occurred on the 26th of July. No examination of the body took place.

THE DESCENDING COLON OPENED IN THE LEFT LOIN.

By A. Baker, Surgeon to the General Hospital, Birmingham.

On the 15th of August, 1849, the author was called to visit Mrs. T——, aged 62, who was suffering from severe pain in the umbilical and hypogastric regions, with retching and vomiting, fulness in the abdomen, flatulence, and constipation. The symptoms were at first attributed to her having eaten indigestible food, and were treated with that view. The symptoms for the most part disappeared, but the pain continued from time to time. On the 1st of October she had a recurrence of the symptoms, not referrible to any obvious cause; and again on the 11th. On the 9th of November, the author was summoned to her, and found many of the signs of intestinal obstruction present, and within reach of the tip of the finger the rectum was found obstructed by a firm growth, occupying its whole circumference. Attempts were made for a few days, and with partial success, to unload the bowels, by passing a small œsophagus-tube into the stricture, by injections, and the use of purgative medicines. In a few days, however, constipation returned, and with symptoms of peritonitis. These symptoms were subdued, and diarrhœa came on; but this ceased spontaneously, and constipation returned, and increased gradually; and on the 17th of January, 1850, perfect obstruction took place. On the 23rd, the symptoms were so urgent, that an operation was proposed and assented to. The descending colon was opened in the left lumbar region, an incision being made transversely across the left loin for five inches. After the division of the muscles and fascia, the quantity of fat which presented itself was so great, that it was necessary to cut away part of it. The intestine was attached by four sutures to the skin before opening it. The opening was followed by the escape of a large quantity of semi-liquid fæces. The daily reports of the state of the patient after the operation are given by the author. She went on favourably, and on the 18th of April, it is reported that she got up, three weeks after the operation; that her general health is good; and that she has gained flesh. The lumbar opening is large enough to admit the index-finger, and the motions pass easily through it. She wore an ivory plug, attached to a padded steel plate, fastened by a belt; but after a time the plate was found inconvenient, and the plug was attached simply to a plate of vulcanized India-rubber. Up to this time, she has remained free from symptoms of intestinal obstruction; but within the last few months, has been attacked with symptoms which indicate that the morbid growth in the pelvis has extended to the abdomen. The author then gives his reasons for preferring the operation in the loin, in this case, to that proposed by Littrè, which were—1st. That there was less risk of rekindling inflammation of the peritoneum. 2nd. That the presence of femoral hernia, which existed in this case, might have given rise to displacement and adhesion of the intestines, so as to interfere with the finding of the large intestine, in an operation at the groin. 3rd. That as the point of obstruction was ascertained, there was no need of any exploratory incision: and he then points out the general advantages of the operation selected. In commenting on the operation at the loin, the author adverts to the fact, that the appearance of the anterior layer of the lumbar fascia may induce the supposition that the intestine is arrived at, as it has at times a bluish-green colour, and looks like intestine. But the longitudinal fibres which characterise the large intestine will not be seen; and on making a careful puncture of the fascia, a protrusion of loose renal fat will take place; and until this fat is reached, the operator may be sure that he has not arrived at the bowel. In speaking of the tendency which always exists, after these and all similar operations, to contraction of the cicatrix, the author expresses his belief that this tendency, in the present case, was materially lessened the habitual use of the plug, which, he says, was a great comfort to the patient, as it enabled her to go about, and mix with the world, without the fear of the accidental escape of the contents of the bowel; and he adds that the patient was able herself to adjust the apparatus, and attend to the evacuations and to the dressing of the wound, without requiring the aid of any second person.

CASE OF INTESTINAL OBSTRUCTION.

By Mr. J. Luke, Surgeon to the London Hospital.

A blacksmith, aged 30, was admitted into the hospital on the 16th December, 1851, under Dr. Pereira, complaining of rheumatic pains in the hips and knees, and with a history of having suffered from rheumatic fever seven years since. It was found, moreover, that there had been no passage through his bowels for five days, that the abdomen was tympanitic, very painful and tender to the touch, and that there was vomiting of all food and drink. The last motion passed had been a copious one. There was inguinal hernia on the left side, reducible. The usual means were employed for four days after his admission, without any abatement of the symptoms taking place. On the third day, the vomiting became fæcal. A stomach-pump tube introduced into the rectum met with obstruction at four or five inches from the anus. The secretion of urine was plentiful; the pulse ranged from 80 to 90; soft and compressible. On the fourth day after admission, a consultation was held, when it was agreed that the seat of obstruction was probably in the upper part of the rectum or sigmoid flexure of the colon. Owing to some abatement of the symptoms this day, the operation was not determined upon. The next day, another consultation took place, and the patient's state having become worse in the interim, the operation was determined upon, and performed by the author. A perpendicular incision, about two inches long, was made above Poupart's ligament, on the outside of the course of the epigastric artery. The incision through the peritoneum was about an inch long, through which the finger being introduced, it was found that the portion of the rectum within reach of the sigmoid flexure, and the descending colon above it, was contracted and healthy. The small intestines were distended, and a portion of them, on being drawn through the aperture, was found to be discoloured. The incision was enlarged to the extent of three inches, and a careful exploration was made, but without discovering the seat of stricture. The patient becoming exhausted, the wound was closed, and he was sent back to bed with an opiate, which was ordered to be repeated at intervals, if

necessary. The symptoms of obstruction increased, the pulse became accelerated and more feeble, and the patient died on the fourth day after the operation. On examination, the small intestines were found to be much distended, and there were marks of recent but not very intense inflammation. The whole length of the colon was found to be empty and contracted; the cæcum contained a hard lump of fæces. About four feet of small intestine above the valve were empty and contracted, beyond which there was a sudden distension of the gut. At this point the cause of the obstruction appeared to exist in a narrow band, which completely encircled the gut from one surface of mesentery to the other, and which was considered to be congenital. About three or four inches below the band there was a diverticulum three inches in length. Adhesions had taken place between the surfaces of the wound, and also between it and the omentum lying in contact with it.

The time of the Society having expired, and there being another paper on the subject unread, it was arranged that Mr. C. Hawkins' paper should stand over until the next meeting, and the discussion on all the cases take place afterwards.

February 24, 1851.

CASE OF STRICTURE OF THE COLON, SUCCESSFULLY TREATED BY OPERATION AFTER THIRTY DAYS' OBSTRUCTION; WITH AN ANALYSIS OF FORTY-FOUR CASES OF ARTIFICIAL ANUS.

By Cæsar H. Hawkins, Surgeon to St. George's Hospital.

In this case a lady, aged about 44, was relieved by the performance of Amussat's operation on the descending colon, in August, 1851, from the effects of nearly complete obstruction in the sigmoid flexure of the colon, and continues in good health to the present time, experiencing so little inconvenience as to be able to enter as usual into society, the artificial anus being kept free by means of an ivory plug of proper size and length, the natural passage being only in part restored. The author proceeded to say, that although M. Amussat could only find six instances of artificial anus, when he brought forward his Memoirs in 1839 and 1841, the operation had been performed in almost every year since that time, and four persons were now living in London, whose lives had been saved by its performance, and therefore he thought that sufficient cases might now be brought together to show what was the real value of the operation in surgery. He had therefore framed tables of every published case with which he was acquainted, and of seven unpublished cases besides his own, for the particulars of which he was indebted to the operators. The tables were divided into those which had been operated on through the peritoneum, seventeen in number, and those in which the bowel had been opened external to the peritoneum, which amounted to twenty-seven cases; and they showed the name of the operator and the date of the operation, with references to the published accounts of each case; the sex and age of each patient; the nature of the obstruction; the part which had been opened, and the mode in which the operation was performed; and the result, with the date of the death or of the last account of the case; and finally, the cause of death and the condition of the patient if alive. The *results* of the operations were next tabulated, from which it appeared (omitting one case in which the operation was performed for fistula) that ten had died within forty eight hours after the operation, and twenty-one within the first five weeks; and that twenty-two only could be fairly considered as having recovered from the operation. It was next shown, that of the twenty-two which recovered, six died in about six months from the time of the operation; others were still alive, or were so at the last known date; and that only *nine* patients were as yet known to have survived as much as one year. Against this apparently unfavourable result the author brought forward proof that, whatever the time was that the patient had survived, the life had in every case been clearly prolonged by the operation, since Mr. Luke's case was the only one in which the fæces had chiefly passed by the natural anus after the operation; in Mr. Clement's case, which lived three years, not even flatus had passed per anum; and in Mr. Maitland's case none whatever had passed naturally after the first two years, although the patient survived the operation seventeen years. A number of tables were next brought forward, but were only partially read at the Society, to show how far the results might be influenced by different circumstances. The sex of the patients did not appear to have any influence; the table of ages showed the curious fact that of eight persons not exceeding thirty, who had been operated on, no less than five had died, while of seven exceeding sixty, only two had died; but nevertheless, the age exerted less influence than might be supposed from this circumstance, since the cases below forty and those above fifty, each showed nearly an equal number of deaths and of recoveries. The table of diseases for which the operation was performed, showed that no less than seventeen were believed to to be cancerous; but although the immediate deaths were slightly increased by the debility of cancer, the deaths of those that recovered were not produced at an earlier period than in non-malignant diseases. It was next shown from the tables of the assigned or apparent causes of death, both in those who recovered, and in those who died in the first five weeks, that scarcely any died of the operation, but that organic changes or other effects of the disease itself could in almost every case be clearly traced as the ground of want of success at first, or of death at an early period after the operation. The tables of the situation in which the artificial anus was made, led to remarks on the comparative propriety of Littrè's or Callisen's operations, from which it appeared clearly right to operate externally to the peritoneum on the right side of the body; but the question was left undecided as to the descending colon, so far as the much smaller number of eight cases, compared with twenty, could decide the point; the dangers of peritonitis, the facility of keeping open the artificial anus, and the errors of diagnosis, being discussed *seriatim*, with reference to the choice of the mode of performing the operation. With regard to the latter point of the diagnosis, Mr. Hawkins showed that very few errors appeared to have been committed in deciding whether the opening ought to be made in the right or left colon, and consequently that there was no necessity for always operating on the right side, as M. Baudens had advised, even when the obstruction was believed to be in the rectum or sigmoid flexure. But the author brought under notice several cases, showing the difficulty of distinguishing whether an obstruction was situated in the small intestines or in the large, and that even when the peritoneum was opened, the seat of the obstruction had not always been discovered, the difficulty being, as it seemed, liable to be increased still further by the existence or supposed existence of a hernia, of which some instances were also given at the conclusion of the paper.

Mr. Norman begged the attention of the Society to one or two considerations in respect to the diagnosis of such obstructions—the real point of importance and difficulty in the question. These had occurred to him for cases that had come under his notice in practice, and he thought them deserving of attention. In the first place, the existence of diarrhœa prior to the complete obstruction. This had been alluded to as occurring in the case given to the Society by Mr. Adams on the former evening, and was the occasion of doubt and difficulty in a case that he (Mr. Norman) had attended some years ago. The subject, an elderly female, had laboured for some days under an attack of diarrhœa; the purging was frequent, though not profuse; and when it ceased, vomiting, which eventually became profuse and stercoraceous, with tympanitis and entire cessation of the ordinary fæcal evacuations, showed that there was a complete obstruction of the bowel at some part. This did not seem to be in the great intestine, on account of the large quantity of fluid which could be injected in enemata, and retained, and there was an entire absence of symptoms by which he, or others who saw the

patient with him, could determine the situation of the obstruction. The patient died, and on a post-mortem examination, the coils of small intestine were found so matted together by old adhesions, that they could with great difficulty be separated from each other, and at length in the lower third of this gut was found a stricture, occasioned by the contraction of the plastic effusions of an old attack of peritonitis, which had reduced the calibre of the gut to that of a crow quill; nevertheless small scybalæ or pellets of solid fæcal matter, were found below the stricture. These had probably passed the stricture in a fluid state, and become more firm by subsequent absorption of the more liquid parts. In the next case that he would name, the diagnosis of the cause of obstruction was rendered difficult by the fact that a previous attack, of a similar character, had terminated happily under medical treatment, and several years of perfect health had been enjoyed. The patient, a respectable tradesman, aged about 50, called on Mr. Norman for advice. Two evenings before, he had "felt bilious," and had taken a dose of pills, which produced some action of the bowels, but without relieving him from any uncomfortable feeling of pain and fulness in the belly, nausea, and flatulence. Severe symptoms of intestinal obstruction, with distension of the belly, vomiting, and a constant pain on the left side of the umbilicus, set in. At length, by the various means used, the symptoms abated, the bowels began to act, the patient came down stairs, and seemed to be convalescent, so that two days before his death he cut out a pair of trousers, being a tailor. The same night, pain and the other symptoms returned with more severity, and were soon followed by a fatal termination. On a post-mortem examination, a loop of small intestine was found strictured in a ring produced by an appendix vermiformis at the end of a diverticulum of the small intestine, which crossed that bowel over the front of the spine, and adhered to the brim of the pelvis on the right side. The obstruction was altogether on the right side of the umbilicus, and below it; the pain altogether in the left side, and above the umbilicus. The patient was attended during his illness by Dr. Babington, Dr. Hare, and Mr. Balderson, along with Mr. Norman. It was in cases such as the above that information was needed to guide us in practice. As regarded the resort to surgical operations, when the rectum was the seat of obstruction, it appeared to him (Mr. N.) from all he had heard, and read, and seen, that the course was pretty clear, and that much important light had been thrown upon the subject by the excellent papers of that and the preceding evening.

Mr. Adams said that the presence of diarrhœa before the occurrence of obstruction, as a diagnostic mark in these cases, had been illustrated in his own case; and he then briefly stated the chief points in it, which will be found in the abstract preceding.

Dr. Murphy inquired whether Mr. Cæsar Hawkins had performed the operation for artificial anus on infants with imperforate rectum, and whether it was likely to succeed in such cases? He (Dr. M.) had had it performed in one case, but it failed—mainly, he thought, from having been resorted to too late.

Mr. Adams remarked that he had omitted to state that, in the case he had related to the Society, the patient now evacuated the bowels comfortably twice a day, and was healthier than she had been for years.

Mr. Cæsar Hawkins had not performed this operation on infants. It had, however, been performed, sometimes with success, sometimes without. Of course much would depend on the individual case and the seat of obstruction.

Mr. Partridge had, in one case of an infant born with imperforate anus, performed Amussat's operation. The child lived a few days.

Mr. Hodgson said that undoubtedly the diagnosis of these cases was the most important point connected with them, and was surrounded with difficulties. It had been stated that the distended appearance of different parts of the intestines would aid us in pointing out the seat of obstruction, but this was an uncertain sign, and liable to lead us into error, for in fat persons, or where the obstruction had long continued, there would be a general fulness, and no certain information could be gained from this sign. We should be aided much in our diagnosis, however, by a very careful study of the history of the case, going fully into its particulars, and inquiring as to where distension was first perceived, and other symptoms. From these inquiries, we might often form a pretty accurate guess where the obstruction was; but the most certain symptom as to whether the obstruction existed in the large or small intestines was to be found in the existence of vomiting and the history of this symptom. When the obstruction was low in the colon, the vomiting did not generally come on until some time afterwards, but when it was situated in the small intestines, it was an early symptom; and if in such cases the vomiting is not stercoraceous, the obstruction may be fairly supposed to be in the small intestines. When the obstruction was in the large intestines, the vomiting became fæcal after the obstruction had existed for a shorter time than when it existed in the small intestines. The cases which had been read at the last meeting of the Society bore out this observation. He thought the preferable operation, when it was decided that the seat of obstruction was below that point, was Amussat's, in the left colon; for it was important that the site of the artificial opening should be as low in the intestinal canal as possible. When the opening was made in the small intestines, the patient became imperfectly nourished, and soon sunk. In Mr. Clement's case, in which the opening was made in the caput coli, and the patient lived about three years, and death seemed to have been induced by atrophy, the body, when opened, was found very attenuated, probably from want of that part of alimentation which was consequent upon the processes which went on in the colon. It was best, therefore, that the opening, when practicable, should be made in the left colon. When this could not be effected, from the circumstances of the case, then the opening should be in the right colon. An artificial anus from the small intestines was justifiable, when the patient was informed that its chance of prolonging life to any considerable length was but very small. The objection to Amussat's operation was, that there was a great disposition in the orifice to contract, and to render the passage of the fæces difficult or impossible. This was no doubt the fact in some cases, but the considerations relating to nutrition above noticed, were sufficient to make an opening in the left preferable to one in the right colon, and still more so, in his opinion, than in the small intestines. After speaking of the services rendered by the authors of the papers to the settlement of the question, he said this operation, as proved by statistics, had been performed with as great a degree of success as many of the great operations in surgery.

Mr. De Morgan remarked that in a case which had been under the care of Mr. Moore, at the Middlesex Hospital, a very simple mode of proceeding was hit upon to determine, in a case of obstruction, that it was not in the large intestines. There was tympanitis to some extent. A tube was passed up the bowel some distance, and an injection thrown up. The stethoscope was then applied to the abdomen, and on changing the position of the patient, the fluid was distinctly heard to traverse the right side. From this it was inferred that the large intestines were free from obstruction. This proved to be correct, as after death a band was found encircling a portion of the small intestine.

Mr. Macilwain thought that in cases of obstruction the operation for artificial anus should be resorted to only as a last resource. He made some strong observations on the employment of powerful purgatives in cases where obstruction existed, and he related some cases, to show their evil tendency.

Mr. Cæsar Hawkins had little to say in reply. With respect to the diagnosis of the seat of obstruction by the distension of the colon above the seat of stricture, this could not be depended upon. This might be air alone, and mislead us in our diagnosis. When there was a soft

and solid state of the colon on examination, it was more likely to aid us in our diagnosis. With regard to the vomiting as a symptom of the seat of obstruction, no doubt, as a general rule, this would hold good, as this symptom generally came on earlier when the small than when large intestines were the seat of obstruction. But in many cases, however, vomiting came on as early when the obstruction was in the large intestines as when it was in the small, and the converse of this also obtained. In his own case, vomiting was an early symptom, but it ceased after a few days. —*Lancet.*

ON THE TREATMENT OF FRACTURES IN THE VICINITY OF THE ANKLE-JOINT; WITH OBSERVATIONS ON THE PRACTICE OF TENOTOMY, AS FACILITATING REDUCTION OF THE BROKEN BONES.

By Richard G. H. Butcher, F.R.C.S.I.,
Examiner on Anatomy and Physiology in the Royal College of Surgeons of Ireland, Surgeon to Mercer's Hospital, &c. &c. &c.

In the *Dublin Quarterly Journal* of last month, there is a practical paper by Mr. Butcher, illustrative of the treatment of fractures in the vicinity of the ankle-joint. A number of instances are recorded, some of them of the most complex nature, yet by the treatment laid down, and the apparatus recommended, the "integrity of the limb and its normal functions were in every instance preserved to the sufferer." Space will not permit a lengthened detail of the several cases and their management, but the concluding observations on the practice of tenotomy in similar cases, we shall transcribe in the author's own words:—

"One of my chief reasons for wishing to place these cases on record is the practice lately brought into requisition in London, in the management of the special fractures under consideration. I allude to *tenotomy*, the division of the extensor tendons, to facilitate reduction, as practised by Meynier, Bérard, Laugier, and other French and German surgeons. A lengthened discussion not long since took place before the 'Medico-Chirurgical Society of London, on the practice of tenotomy, in some cases of fracture, when Mr. C. De Morgan related some cases in illustration.'* In the first cited, the tendon was not divided until the day after the accident. 'The second case occurred in the author's own practice. The patient was a female, aged 66, of drunken habits, and was admitted into the Middlesex Hospital in March, 1849. She had been knocked down by a cab, and both bones of one leg were fractured a little above the ankle.' The report goes on to say:—'The author divided the tendo-Achillis on the ninth day, with instant relief to the suffering of the patient, and immediate removal of all untoward symptoms.' A very important feature in the management of these cases has been omitted altogether: the manipulation adopted for the reduction of the fracture, and the position in which the limb was placed afterwards. In the second case, it is stated that 'the tendon was divided on the ninth day.' I can easily understand that this might be requisite, if the fracture, with its attendant deformity, was left unreduced for that length of time; failure of the therapeutic means employed; and the spasmodic action of the extensor muscles thus prolonged; for if fractured bones be left unreduced for such a lengthened period as this, *permanent* spasm seizes on the muscles and becomes established; a fact clearly pointed out and insisted on by Sir A. Cooper. Mr. De Morgan goes on to say—'In the cases related, the chasm between the divided portions at first did *not* exceed a quarter of an inch, that being sufficient to get the bone into position; and in a short time after there was no appreciable space at all.' This admission goes still further to proclaim that there is no necessity for division of the tendon to effect reduction, if the case is seen early; for by flexing the thigh as I have recommended, we can relax the extensor muscles more than 'the quarter of an inch, that being sufficient to get the bone into position.' I am of opinion that in ninety-nine cases out of a hundred, there will be no necessity for division of the tendon to effect reduction, if the limb be treated as I have advised; nay, on the contrary, I think, in some instances, the division of the tendon would be very injurious, as removing the support posteriorly from the ends of the broken bones, and thus permitting displacement in that direction. The mode in which the fracture box, which I have described, supports the leg in a horizontal line, with the thigh slightly flexed, padded, and cushioned, as illustrated by the foregoing cases, meets every requirement of the surgeon. Dupuytren's splint, in conjunction with these means, as used in some of my cases, is a most admirable adjunct; but, taken by itself, it will not answer as well for the management of the form of fracture under consideration; for if the limb be done up as directed by Dupuytren, and placed flexed upon its side, some lateral displacement will take place; or if, with the splint so applied, the leg be allowed to rest upon the heel, it is unsteady, and rolls about, and the entire limb is in the extended position—a posture very objectionable, as making tense the tendo-Achillis.

From a review of these cases, and the observations upon them, the following facts are, I think, deducible:—

1st. That by proper position of the limb, and early reduction, co-aptation of the broken fragments can be effected, and spasm averted.

2nd. As the result of the broken bones being kept in accurate position, irritation is subdued, excess of callus prevented, and the motions of the joint left unimpaired; a fact of great practical importance here, for the experiments of M. Cruveilhier prove that various forms of irritation will make the periosteum and ligaments ossify, and it has been ascertained that in some cases of fracture near the joints the ligaments have sometimes been converted into bone, and M. Rayer has observed, from numerous interesting experiments, that a similar change may be exerted not only in the fibrous but also in the cartilaginous structures.

3rd. That tenotomy is not called for in the vast majority of cases, being perhaps only admissible when permanent spasm has located in the extensor muscles, owing to neglect of early reduction."

* I quote from Braithwaite's Retrospect.

INFIRMARY REPORTS.

REPORT OF THE SLIGO COUNTY INFIRMARY.

By W. S. Little, A.B., M.D, T.C D., L.R.C.S.I., and Licentiate in Midwifery, Lying-in Hospital, Rotundo.

In presenting you with a Second Annual Report of the Sligo County Infirmary, I have preserved the form and arrangement of the statistical tables, which (as on a former occasion) will be found to embrace a full, accurate, and faithful account of the proceedings of the past year, ending January 5, 1852; comprising minute details of the financial and professional ministrations of the institution, so classified and arranged as to be comprehended almost at a glance.

The system of professional attendance adopted is as follows:—I am never myself absent for a day, except when engaged in urgent and distant country business; but the number and nature of my other occupations totally preclude the possibility of my naming a certain hour for my infirmary visits, except on Tuesdays and Fridays (our extern days), when I endeavour to make such arrangements as will enable me to attend punctually at the appointed hour—viz., one o'clock. All cases of accident, whether trivial or otherwise, and cases of sudden seizure of illness in the house, I also attend personally, and at once. At eleven a.m. and at seven p.m. the hospital is visited by one of Dr. Johnston's apprentices (at present that duty is very punctually and efficiently performed by Mr. Hamilton),

who dresses ulcers, issues, and operations; applies leeches and cups; attends to ophthalmic and other cases requiring manual interference; sees that the patients have a supply of medicines; and reports irregularities or complaints. Dr. Johnston attends in the afternoon to compound my prescriptions of the day, and also attends accidents, as many such, as dislocations, fractures, and others require assistance; thus four professional visits at least are daily paid to the house, which, with the attendance of an experienced nurse in each ward, it is to be presumed, afford our patients all the advantages which any public institution possibly could confer, and more than any private individual, whatever his means, could command.

The compounding department is conducted in the most satisfactory manner; the labels containing, not alone the directions, but the prescriptions in full, so that any medical visitor, without the trouble of consulting our clinical books, by these means, and by consulting the bedside labels, can at once criticise the accuracy of our diagnosis and the propriety of our treatment. This system is a guarantee for the careful discharge of the duties performed, which only the professional visitor will be able duly to appreciate.

To efficiently conduct the duties of a large county hospital, containing, as it ever should, carefully selected cases, is a more laborious as well as a more responsible vocation than is generally supposed; and I should be particularly obliged if our governors would occasionally verify this observation by visiting the house when I am engaged in its wards. A ward of twelve beds occupies me at least a full hour on an average of one day with another; stethoscopic examinations, urinary analyses (rough though they be), and patient investigation of disease and its phenomena, being practised more in detail, and with more minuteness than the impatience and habits of private patients will sometimes permit.

With respect to complaints by patients to governors, I beg, most respectfully, to offer a few remarks. It is not to be expected that a public institution like an infirmary will give satisfaction to all; cases are admitted, indeed forced upon us, as chronic dropsies, consumptions, inveterate scrofulous and cutaneous affections, incurable ophthalmic cases, old dyspeptic and digestive derangements, &c., for which nothing can be done. Such present themselves, frequently from a distance, with pressing letters from governors, without a farthing to bear their expenses at lodgings, and buoyed up with a last hope of benefit to be derived from infirmary treatment. It would be a great cruelty to refuse such, while on the other hand it is an injustice and an absurdity to admit them. When such are sent home as bad, or worse than when admitted, an experience of twenty years medical charity work has satisfied me that, no matter how great the care and kindness lavished on them, it follows almost as a law of nature that "the doctor" is disparaged, and the institution he conducts abused in no measured terms; when such persons, either of themselves or in answer to inquiries, complain of inattention (either on my part, or on that of any other person connected with the hospital), it would confer the greatest obligation on me if such were at once referred to myself for explanation, when I shall always be able (from our system of registry and clinical reports) to explain every minute circumstance of the case, from its admission to its discharge. Gentlemen acquainted with public business, and public institutions and their officers, must know that a complaint formally urged before a board of governors carries with it a certain *prestige* in favour of its truth, which, however complete the refutation, reacts injuriously on the institution and its medical officers. In alluding to this subject, I am happy to be able to state that I do so rather with a view to the future than in reference to the past; for during the two years and a half that I have conducted the infirmary, I have heard of but two instances of *alleged* inattention, neither of which had a shadow of foundation.

The additions of the old infirmary, now in progress of erection, and in a state of great forwardness, according to the excellent plans of the eminent architect, W. D. Butler, Esq., will give the county of Sligo the very best provincial hospital in Ireland. Indeed, I can assert from my own knowledge, that it will be superior to many, and inferior to none in the metropolis itself. The provisions for heating, ventilation, and light; the introduction of day-rooms for convalescent patients to sit and take their meals in; the rapid removal of slops and all other nuisances by soil pipes attached to each ward; the comfort, cleanliness, and economy of time and labour secured by adopting the system of "lifts;" the various improvements in the water-closet, bath-rooms, laundry, and kitchen departments; the complete separation of the male and female patients; the better classification of cases which the new and enlarged arrangements of our accommodation (to the amount of eighty beds) will admit; and the scientific attention which has been paid to the most minute essentials of hygiene, even to the arrangement of the patients' beds, will render your new infirmary, when in full working order, as perfect a structure for its purpose as can anywhere be found.

In addition to the above remarks, which appeared in my last Report, I have to state, for the information of governors at a distance, that the adoption of the hot-water system of heating (for which the managing committee have contracted with Mr. Harrison of Limerick, and for which Mr. Butler has arranged an appropriate plan of ventilation), and the lighting of the new house with gas, will supply everything that could possibly be desired for the comfort, efficiency, and even elegance of a public hospital.

The heating of apartments by the simple expedient of the circulation of hot water through metal tubes, though extensively applied in London, and England generally, and in the north and south of Ireland, to the purposes of large factories and public institutions, has not been as yet adopted in hospitals, as far as I am informed on the subject: but upon an examination of its capabilities, it appeared to me to present such indisputable advantages in respect of economy, safety, cleanliness, and health, that I had no hesitation in strongly recommending its adoption. The large metal tubes will completely surround each ward: from a great extent of surface, and from all parts of the apartment at once, gently heated currents of air will be constantly ascending, free from the impurities which coal fires, particularly at night, even in the best drawing chimneys, are perpetually evolving. The occupant of each bed will equally feel the benefit of such a system of heating, while under the old system of fire-places one was uncomfortably hot and another as uncomfortably cold. It will also entirely prevent that nuisance of hospitals—viz., patients huddling round a large fire, and smoking by stealth, and, upon a sudden interruption, sticking heated pipes under the bolster or bedding. The contractor undertakes—in the case of the Sligo Infirmary—to make two small furnace fires do the work of sixteen, and engages us a maximum temperature of 65 to 70 degs. Fahrenheit, easily regulated by dampers, while from 55 to 60 degs. is as much as we shall ever require.

Upon referring to the report for the year 1851, I have the satisfaction to find that the average expense of each bed for the year has decreased from £23 17*s.* 10*d.* to £21 2*s.* 1*d.*; and of each patient, from £2 3*s.* 4*d.* to £1 18*s.* 4*d.*: this is accounted for by the greater number of patients admitted during the latter period, it being obvious, that when once a suitable building has been procured, and a certain definite staff of officers appointed, the average expense of each patient must seriously increase with the decrease of numbers, and *vice versa*: thus—as I stated last year—while fifty patients cost the county £1100 per annum, thirty additional inmates can be maintained for the comparatively trifling cost of £273.

From many infirmary reports of the last year I find that our dietary is very much more liberal than that of any similar institution; and yet when it is ascertained that it costs but 3¾*d.* per diem (a small part of the total expense of a patient), I am confident it will not be objected to. In some respects, however, it is faulty; and I intend, on an early day, to bring the subject of its amendment before the managing committee.

In connexion with the subject of the great increase of accommodation which the new infirmary will afford, there is a matter well worthy of the consideration of the governors and the public.

There is a large and well-deserving class of the community, particularly in large towns like Sligo, who are placed in a very anomalous position as respects medical relief—I allude to shopmen in merchants' establishments; the humbler class of shopkeepers themselves; tradesmen and artisans, occupying a place midway between the very prosperous and the very indigent; public officers of an inferior grade and their families; small farmers; and perhaps in these times so prolific in pecuniary reverses, we might include decayed gentry; all of which classes are very much worse off, under illness or accident, than the infirmary patient or even the workhouse pauper. I conscientiously believe, and dwell with pleasure on the fact, as a peculiar and distinguishing feature of our profession, that no medical man will be found to refuse his gratuitous aid and advice to persons so circumstanced, but the same laudable pride which keeps them from the infirmary or dispensary, will often prevent them incurring a personal obligation; and it has often happened to me to see valuable life sacrificed to the fatal delay engendered by these scruples.

Two small *pay wards*, of five beds each (male and female), would, at the average duration of a patient's residence in hospital—viz., thirty days, afford all the comforts and advantages of a more than moderate income to about 120 patients of this class per annum, during an illness which must otherwise be comparatively neglected or maltreated. A charge of ten shillings per week would amply repay the institution, while it would obviously place those advantages within the reach of very limited means, and at the same time do no violence to a proper sentiment of independence; but on the contrary, be productive of a feeling of confidence in the treatment and attention bestowed, which, I regret to say, a purely gratuitous benevolence rarely begets. If fully and constantly occupied, the sum derivable from this source during the year—namely, £260—would *all but defray the entire cost* of the thirty additional beds, while it could not be objected to the proposal that its objects are not fully as much in need of, and greatly more deserving of the boon, than the vast majority of our present patients.

On this subject I have to add to the above remarks (which appeared in last year's Report), that the two small wards on the first floor, intended for eight beds each (but which would be fully furnished by six of a larger and better sort), are most admirably suited for the proposed purpose. The nurses' room lies between and communicates with each, and they open on the day-room. They also contain fire places and grates (being a portion of the old house), which might occasionally be required among this class of patients.

I have great pleasure in being enabled to state, that in every department of the institution the several duties are entrusted to a willing and efficient staff, who perform them entirely to my satisfaction. To my professional brethren of Sligo, I return my best thanks for their valuable assistance in operations and consultations—an advantage of the utmost importance to the institution.

LIGATURE OF EXTERRAL ILIAC ARTERY.

By Mr. Lloyd of St. Bartholomew's Hospital.

A. B—— is a man about 25 years old, who, four months before the operation, had a bubo in the left groin, which took on a phagedenic action; hæmorrhage occurred several times, and seemed to increase with each attack. The bleeding generally stopped of itself, but was in the last instance so profuse that he was extremely alarmed. The destructive ulceration began now to diminish, the hæmorrhage did not recur, and the bubo healed perfectly. But it would appear that the plug which had prevented the further bleeding from the ulcerated opening which had probably occurred in the femoral artery, gave way after the cicatrization was completed; or that a sac was slowly and gradually formed during the healing process; for about one month after the cicatrix had been formed, a pulsating tumour, of the size of a walnut, was noticed in the groin.

The patient was admitted, October 20, 1851, the tumour being rapidly increasing, and situated in front of the thigh, and above Poupart's ligament. Mr. Lloyd, with the full concurrence of his colleagues, proceeded, on October 24, to tie the external iliac artery. The operation presented some difficulty, as the tissues were somewhat thickened, and the subject very fat. When the peritoneum had been pushed aside, the incision having run in a straight line from a little above Poupart's ligament to the anterior superior spinous process of the ilium, the vessel was found so deeply situated, that Mr. Lloyd could not take hold of it with his finger and thumb, but was obliged to press it against the brim of the pelvis.

Mr. Lloyd stated, after the operation, that he anticipated a certain amount of trouble, as the patient had latterly been affected with syphilis and phagedena; and these fears were not idle, for severe secondary hæmorrhage occurred about five weeks after the tying of the vessel. This was stopped by timely compression; and on February 19, about four months after the deligation of the artery, the wound was quite healed up, and the patient on the point of going into the country. The pulsations had ceased immediately after the securing of the vessel, and the sac had been emptied of its clots a few days afterwards.—*Lancet.*

REVIEWS AND NOTICES OF BOOKS.

PHYSICIAN AND PATIENT: or a Practical View of the Mutual Duties, Relations, and Interests of the Medical Profession and the Community. By Worthington Hooker, M.D. 12mo. pp. 453. New York.

Casting an eye over a review of this book in the *American Journal of Medical Sciences*, it occurred to us that it contained many paragraphs which might be printed as fragments of medical ethics for the benefit of our readers. With this view we put together the following selection of the sayings both of author and reviewer, unmixed with any observations of our own:—

"The quackery which is practised among medical men is a much greater evil than that which is abroad in the community. I attack it, therefore, with unsparing hand. . . . When the rules of an honourable professional intercourse shall come to be properly understood and appreciated by the public, one of the great sources of quackery will be removed."

How far it was prudent to expose the errors of physicians to the public may very reasonably be questioned. For ourselves, we are altogether persuaded that such a course is most unwise, for it seems certain that nothing can tend more to impair the confidence of the public in the medical profession, than an acquaintance with the errors and crimes with which so many of its unworthy members are justly chargeable. *Il faut laver son linge sale en famille* is a wise saying, as all experience proves. The errors of good men and the crimes of knaves, are never discriminated by the vulgar, who have a keen relish for detecting blemishes in all who are by position or knowledge superior to themselves. The innate proneness to quackery, moreover, of many who would feel shocked at being classed amongst the vulgar, is encouraged by everything that palliates their folly by seeming to afford a reason for distrusting the power of medical science. By one of the commonest acts of false reasoning, they attribute to the whole profession the errors of its unworthy members, and to the art of medicine the mischiefs which its counterfeits occasion. . . . . In this country, quackery is most prevalent in those regions precisely where intelligence is most developed by education, and where the habit of judging without appeal on every question that can employ the intellect is nearly universal. The same is true of Europe, so far as it can be in countries where the governments have not yet got rid of that antiquated notion, that they are responsible for the character and attainments of those who are to have charge of the people's health. . . . . .

Under the title of "Popular Errors," is a notice of some of the prevalent fancies of the vulgar in regard to disease. The prejudice in favour of heroic treatment, of specifics, &c., the notion that medicine is essentially curative, the *post hoc ergo propter hoc* mode of reasoning in therapeutics, the idea that disease is a palpable entity, which medicine is to exorcise like an evil spirit from the economy, &c., furnish themes for very

sound and sensible commentaries upon popular errors. Still, it should not be forgotten that these very notions which we blame or ridicule, had their origin in the medical profession itself; each was in its day the epitome of some theory invented by ingenious philosophers, and afterwards cast forth as part of the rubbish of our science At this moment the popular language of France, and to some extent even of our own country, deals in phrases about "irritation," which were inoculated upon the parent stock by the disciples of Broussais. If the people give currency to terms which we now denounce as valueless or absurd, it ought not to be forgotten that the spurious coin is the issue of our own mint.

The most prominent of quack remedies may be arranged under three heads—viz., evacuants, alteratives, and cures for incurable diseases. The first, by producing a decided and sudden impression on the system, must often produce a salutary change in chronic diseases of the digestive organs; the second, including tonics, has evidently a large field in which they may do more or less good; and the last appeals to that desire for life which seldom abandons the sufferer even in the most desperate extremity. Yet, even allowing to these various agents all, and even more than all, the real efficacy they possess, it is evident that their virtues would form a very flimsy basis for the reputation they enjoy. Secrecy is the most potent ingredient in them all; the moment their actual composition is known, their value is reduced to a very low point. *Omne ignotum pro magnifico*, is the device under which quackery of every sort obtains its largest conquests. Secrecy, which in such matters is itself imposture, also infallibly leads to falsehood of a more direct kind; and he who does not scruple to keep secret the nature of a remedy which he alleges to be useful, will have no hesitation in fabricating proofs of its efficacy.

"One who had been an apothecary (relates our author) and who had sold large amounts of quack medicines, stated that in one year he sold three thousand dollars' worth of one medicine; that he had no satisfactory proof of its having cured a single case of disease; that he had obtained, however, many certificates of cure, but not one from any person who had paid for the medicine." . . . . . .

That quackery should be more rife at the present day than it has yet been, is but a natural consequence of evident causes, and it needs no prophetic vision to foresee its future vast extension. If medicine were its only field, some hope might be entertained of its expulsion; but there is not a branch of human knowledge or action in which its dominion is not securely established. When we, as physicians, wonder at the confidence reposed by so many thousands in pretenders to medical skill, does it never occur to us that we are equally prone to place confidence in quacks of a different kind; that all our education, and all our abhorrence of being judged by incompetent judges, do not prevent us from following errorists in religion, sciolists in science, pretenders in art, smatterers in literature, and deceivers in politics? If, when knowledge was less diffused than at present, and the votaries of error, attracted by authority, blindly accepted what they were told to believe, the dupes had at least the merit of hearty attachment to their false guides; but in this age of boasted enlightenment, we have the more pitiable spectacle of a self-sufficient pride in ignorance scoffing at the lessons of experience and wisdom, and arrogantly claiming the right of every one to be "a law unto himself." The pride which every one feels in being able to pursue his own calling intelligently, moves men to sit in judgment upon subjects which neither their talents nor their education fit them for comprehending; and since the partial enlightenment which has developed this baneful fruit must constantly become further and further extended through all classes of society, there is every reason to apprehend that the vices we have now to deplore will become more and more developed through many succeeding generations. . . . . .

The confidence of the people in any false system of medicine grows entirely out of the promises which its promoters are bold enough to make, and bears not the slightest proportion to its intrinsic worth. As long as physicians shall esteem it disgraceful to lie, they must be content to have their patients filched from them by those who are passed masters in this bad art; but as honest men they have little cause to repine at the gains which, in every other pursuit, as well as in medicine, are the wages of iniquity. These remarks are not, as a whole, applicable to homœopathy, for of that illusory art we may in charity suppose that there are many conscientious professors; since the mischiefs it gives rise to are for the most part of a negative character. It does not kill its victims; it only lets them die. Dr. Hooker, as many other writers have done, demonstrates its nullity as a science; and as a profession, he calls attention to the shabby array of its members, to prove how small a hold it should have upon the respect of educated and intelligent men. On a survey of their ranks, he remarks:—

"No superior order of talent would be found among them. There would be none who are distinguished for true research; none who have made any respectable additions to the literature of medicine, or to its store of experience; and none who had ever had any commanding influence."

Of this subject of homœopathy, we are of opinion that enough has been written; in a work like the one before us, it is true that a critical history of its absurdities finds an appropriate place, but we cannot persuade ourselves that it is worth the ammunition of reason, and sarcasm, and denunciation, which has been expended upon its flimsy structure. As a system, it is almost effete in the land of its birth, and we should perhaps do well not to warm it into life at the fire of controversy. . . . . .

That any system of quackery, or any system *deduced* from a pathological hypothesis, should succeed in curing a sufficient number of cases to keep it alive for a longer or shorter space of time, depends upon two causes; the first of which is that, out of the whole number of cases to which it is applied, it acts favourably upon a certain number. If it be a sedative plan, it can hardly fail to do good in many of that large class of inflammatory diseases; if it be an excitant method, not a few cases of sthenic affections in the forming stage, and not a few cases of a dynamic type, will demonstrate its utility; finally, if the disease, of whatever type, attack a constitution capable of successfully resisting and at last overcoming its downward pressure, it offers an appropriate field for the triumph of infinitesimal doses.

"In a great majority of cases of sickness which fall under the care of a physician, the *vis medicatrix naturæ* is competent to effect a cure if they are left to themselves; and in most of them it will do so, even though a positively bad treatment may be pursued." . . . . . .

Points in which the practice of the really skilful physician differs in its results from that of the injudicious practitioner and the quack:—

"1. He has a less number of fatal cases, in proportion to the whole number that come under treatment.

2. He has a less number of bad cases, because he avoids converting light cases into grave ones, and succeeds in many cases in arresting disease in its very commencement.

3. His patients have commonly a shorter sickness.

4. They are in a better condition after they have recovered, less apt to have bad results left behind, and less liable to disease in future.

5. He has a less number of patients, and a smaller amount of sickness, in the same number of families." . . . .

How shall the community judge of physicians? If, as had been previously shown, the community is entirely incompetent to form a just judgment of medical men and their art, upon any scientific ground whatever, what guide shall they follow in making choice of the physician who is to be entrusted with their own and their families' health and lives? Surely, they ought to have some good reason for so important an act. Every one knows how the choice is usually made, and that no stronger motive than personal partiality determines it, even in the absence of any proclivity whatever towards irregular systems. But where there is an itching after novelty, common rumour—that fertile mother of the whole spawn of quackeries—vouches for the skill of the charlatan, and the profundity of his doctrine. It would be an amusing, were it not a pitiable sight, to see many persons of intelligence and education imagine that when they call in a quack they are actually making proof of independence and superiority to vulgar prejudice; whereas, if they would but examine the real links in the chain of influences which has led them to this result, they would find that so far from acting independently, they have in reality followed the example, not of the wise, not of the good, not of the skilled, but of the ignorant and self-willed multitude, or obeyed the voice of their own worst passions—their vanity and pride. "The worst of all ignorance," said Socrates, "is the conceit of knowing what you do not really know." What, then, with the wise in their own conceit, who reject all sound advice upon the subject, the ignorant, who are quite unable to form an opinion, the enthusiasts who are joined to their idols, and those who walk in the steps of their forefathers as the only right way, it is plain that the number who are likely to

profit by the advice conveyed in this chapter, must be extremely small. . . . . .

"How to choose a good physician?" In the first place, the evidence of his having received a thorough education should be examined as the primary qualification of a physician. "But education in the science of medicine is practically despised by quite a large portion of the community" to use the popular formula; "the fact that the physician is successful in treating disease is worth vastly more than a piece of parchment." Indeed, we are persuaded that the half-educated or the wholly ignorant man, who has boldness enough to make high pretensions, and adroitness enough to palm off natural effects as the result of his skill alone is almost sure to inspire more confidence than the conscientious, and therefore circumspect physician. His very ignorance is a charm; he is supposed, by the intuition of his genius, to discover more than the learned practitioner can do by study and observation; not a few, even, of the genteel vulgar, imagine that he has a "gift" which makes him quite independent of the ordinary processes for acquiring skill. Unfortunately, this error is fostered by an equally gross one in the profession itself. There are so many physicians of little talent and less learning, and who openly affect to disdain both, as compared with tact and experience, that we ought not to wonder at the large number beyond our limits who despise what our own brethren undervalue. How large a number, too, of those who annually enter the profession, whose general and literary education is absolutely null, and who have been made doctors of medicine after a period, we will not say of study, but of attendance upon lectures, which is only sufficient to reveal the impossibility of their ever being fit to treat disease. So long as a large proportion of medical men are wholly uneducated, or only instructed enough to make them dangerous to the sick, we have no right to complain that the public prefers employing professed charlatans rather than those who, with the title of doctor, have none of the accomplishments which belong to so honourable a name. It is to our disgrace, as a body, that we do not insist upon a higher standard of professional and general education than is now exacted. It cannot be expected that men who have never formed habits of study in early life, who know little or nothing of the art of observation, or the science of reasoning, should become really accomplished physicians. That they may have a reputation for sagacity and success among their patients, and even amongst a certain class of their brethren, is very probable; but that they should become really consummate practitioners, is next to impossible. Rhazes, says Dr. Forget, although he belonged to the empirical school, declared that "he would have more confidence in a physician who had never seen a patient than in one who was ignorant of medical literature." Hecquet was wont to remark, "Il y en a qui voient beaucoup de malades, mais je vois peut-être plus de maladies." But the public fancies that the seeing many patients is experience; it cannot understand that he who sees them with his natural eyes only, may be stone blind to every thing in them which it is the province of the educated physician to perceive. To bring the public, then, to a sense of this error, it is necessary that they should have a degree of intelligence and special instruction which they cannot be expected to possess, and least of all in a country where every avocation is open to men of the lowest capacity and attainments. . . . . .

A much safer guide than that which has been considered, for discovering the merit of a physician, "is to be found in the unbiassed opinion of his medical brethren." This test, it is true, cannot readily be applied by one who is about to choose a medical adviser. He can hardly discover what the opinion of the profession is, for if (as our author suggests) some of the brethren are unjust through prejudice, many more will run to the opposite extreme, and, to avoid the suspicion of injustice, palliate the faults and perhaps exaggerate the abilities of their rival brother. Besides, it is not to be concealed, that professional excellence is not the only title to the confidence of the public which a physician should possess. He ought also to be richly furnished with those humane sympathies which will secure to him the love and confidence of the families which employ him; indeed, he will have perpetual occasion to exhibit them, and comparatively very seldom to display a high degree of professional skill. The estimate of his brethren, therefore, founded upon the degree of his proficiency in medical science, is not always a reliable guide to those who seek something more in their physician than dexterity in the diagnosis and skill in the treatment of disease.

To ascertain whether a physician possesses the mental qualities which are essential to his being a skilful practitioner, "let one observe the mental qualities of the physician, as they are exhibited in regard to any subject with which he is himself familiar in common with physicians." If the physician is observed to be credulous about politics, religion, or the occurrences of the day, he may be inferred to be inaccurate in his observations of disease; if he is a sceptic, "his treatment of disease will be marked by hesitation;" if he forms his conclusions hastily, he is unfit to manage serious and complicated cases; if he is unduly slow in making up his mind upon ordinary occurrences, and obstinately fixed in the opinions he has formed, he will not be ready to adopt those changes of treatment which the course of disease requires. To determine whether he is a good observer, his mode of examining patients will not suffice, for the layman cannot judge of the necessity or appropriateness of his queries, and, according to Dr. Hooker, "minuteness of examination is in fact one of the most common tricks of the trade." We here remark, *en passant*, that it is a thousand pities the "trick" were not more common; it is rather too laborious a one to suit the fancy of a charlatan. . . . . .

We are disposed to admit the value of these rules in many cases, but by no means in all. They may be true in their positive application, at least generally, but negatively they are useless to guide inquirers. If a physician really possesses a logical mind, is cautious, yet decided, of precise and upright judgment, a good citizen, neighbour, and parent, undoubtedly the union of all these qualities renders him most probably a skilful and prudent practitioner. But the negative of the proposition is not equally certain. There are not a few physicians who possess profound knowledge and consummate skill, and who are nevertheless mere children in non-professional matters; who are totally ignorant of, because they are careless of, the ways of the world in various matters which absorb the interest of the community; who even are so alien to the common sentiment, as actually to think infinitely of their patients' lives, and not at all of their patients' fees; who yet, we say, hold the first rank in the love of the community, and the honour of their brethren. . . .

"One of the prominent faults of the medical profession in the nineteenth century is that it is, as a body, too fond of new things and too much disposed to receive them upon doubtful evidence. There is a great disposition to hail every new remedy with enthusiasm. The annals of medicine are, therefore, burdened with false statements in regard to the effects of remedies. Though the public think that there have been of late many discoveries of new medicines of great value, there really have been but few. There have been many improvements in the *forms* of medicines. I mention, as examples, quinine and morphine, the active principles of bark and opium. But there have been but few absolutely new medicines introduced which are of any importance. . . . And it may be remarked that physicians who try all the new remedies recommended from time to time in medical journals, do not add so much to their stock of available experience as those who are more cautious, and less ready to adopt every thing which is new." Scepticism "not only narrows the limits of knowledge, but actually leads to positive error. The sceptic, in his demand for stern fixed facts, rejects some facts which are established by evidence that is sufficient to satisfy any mind possessed of candour and common sense; and the rejection of a well proved fact, being itself an error, must necessarily lead to other errors. The sceptic, too, with all his doubting, is always, to some extent, and on some points a credulous man. As he doubts on some points against clear evidence, so he will assuredly believe on others against evidence just as clear. His beliefs are no more worthy of confidence than his doubts." . . . . .

But the most mischievous promoters of error in regard to medicine, the most industrious coöperators with the unprincipled gang that infests the community, periling and even destroying the lives of the unfortunate persons who confide in them, are in reality to be found in the most educated classes, among those who, according to our author, "are intelligent and judicious on other subjects," or, at least, are so in the ordinary affairs of life. They may be acute lawyers, eloquent preachers, sagacious merchants; but one thing they assuredly are not—men of well-balanced minds. In hardly any instance is a person of this class to be found promoting quackery in medicine without fostering it, at the same time, in some other department or pursuit; he will assuredly be seen fighting under the banner of some new-fangled religion; will be noted for his zeal in what is called "reform," which too often means the destruction of a substantial reality, and

the substitution in its place of some fantastical chimera; or will be ardently industrious in some of those philanthropic associations of which each one promises to be the salvation of mankind, though it may bring present and direct ruin upon thousands, &c. &c. It were in vain to include in a few sentences a catalogue of the absurd doctrines, wild schemes, and mischievous practices which are invented and promoted, and even believed in, by these superior persons. They are self-reliant people; they imagine that they have a lever with which they can move the world, even without the fulcrum which Archimedes postulated; the virtues of faith, contentment, and humility, find no resting place in their tumultuous bosoms; they expect to usher in a millennium of peace by teaching that every man shall be "a law unto himself," and thus setting every man's hand against his brother. Such are the persons of whom our author has more hope than of the ignorant crowd, with whom addiction to error is a matter of sentiment only, and not of reasoning. He will pardon us if we think that the nature of the case proves him to be mistaken, and that all experience confirms our opinion. . . .

There can be no doubt in the minds of any who have observed the medical profession in Europe, that a very large portion of it is inferior to our own in the qualities which should distinguish gentlemen; that it is characterized by a much lower notion of personal dignity and honour than American physicians entertain; and that its conduct is much more frequently tarnished by meanness and sordidness of sentiment. The reason is perhaps not difficult to discover. In the United States the liberal professions contain the real aristocracy of the nation, and medicine numbers amongst its cultivators and practitioners thousands who occupy the highest social rank. In Europe, on the other hand, there is first the titled nobility, then the army and navy, the clergy, and the bar, who all outrank the medical profession, because through these pursuits alone is the road open to political preferment. They absorb nearly all the young members of respectable families, and the ranks of medicine are chiefly recruited from the humbler classes of society. It is not, therefore, to be wondered at that—in point of personal character, of honourable sentiment, and of dignified demeanour—the medical profession of the United States ranks the first in the world. These peculiarities are sufficient to explain why a judgment like that above quoted from Simon is clearly inapplicable to American physicians. They also explain why the principle of association, and the habit of harmonious action, are so effective and prevalent with us, and so rare in transatlantic communities. Of these, the English approaches nearest to our own in organization, and the English physicians excel all others in Europe in their social rank, and their sense of personal dignity.

By these remarks, we have no intention of proclaiming the complete exemption of our medical countrymen from the low tricks and sordid aims which are too common in other countries—much too common in our own—but only to maintain that, as a profession, we are not justly chargeable with them. Our author points out a number of particulars in which not a few of our brethren err, and supply but too real grounds for a "railing accusation." We can only enumerate them:—Professional cliques, and alliances with various societies, social, moral, or religious; controversies upon medical subjects; the interference of physicians with one another's practice. These are forcibly dwelt upon as some of the means by which the harmony of the profession is disturbed, and modest merit condemned to languish, while mediocrity grows prosperous upon the fruits of shameless presumption, combined with artful sycophancy.

ON A NEW TEST FOR UREA.

By Baron Liebig.

For several months past I have been occupied with experiments on a new process for the determination of urea in urine, by means of the nitrate of the binoxide of mercury. Urea combines with this, and forms a snow-white, almost insoluble compound, which is immediately precipitated when urine, or a fluid containing urea, is mixed with a solution of the nitrate of the binoxide of quicksilver, containing no free acid. The precipitate contains one atom of urea, one atom of nitric acid, and four atoms of the binoxide of mercury. There is also a compound, which is beautifully crystalline, and which, for the same quantity of urea and nitric acid, contains only two atoms of the binoxide of mercury. In a liquid which contains merely urea, we can accurately determine the quantity of this principle in a few minutes to ¼ per cent. by means of a standard solution of the nitrate of the binoxide of mercury; but the presence of common salt, in urine, creates some difficulties, which yet require to be got over. Urea also combines with binoxide of mercury. I have obtained three compounds, which respectively consist of one atom of urea, with two atoms, with three atoms, and with four atoms of binoxide of mercury.—*Phar. Jour.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MARCH 17, 1852.

OUR EXCHANGES WITH FOREIGN JOURNALS.

Great disappointment is experienced in consequence of ignorance or neglect of the postal regulations respecting the transmission of journals to and from the Continent and the United States. These regulations are not very explicit or intelligible, and verbal explanations of their import we cannot obtain; but as far as we can judge, periodicals from the Continent are charged here sixpence, or twelve sous, if they exceed *two ounces* avoirdupois (being 875 grains, or nearly 57 French grammes), and twopence per ounce for every additional ounce. Periodicals stamped as newspapers we receive regularly, but others exceeding the above weight, we are obliged to refuse, on account of heavy postage. The last *Annales d' Oculistique* from Brussels was charged tenpence, or one franc, as was the *Archives Belges* from the same place, and the *Revue Medico-Chirurgicale* from Paris. From the United States several have lately been presented charged from a shilling to seven-and-sixpence each; one being apparently the *Charleston Journal.* These and other difficulties obstructing the interchange of books and journals between this and other countries are greatly to be deplored. At the moment we write we find it so difficult to transmit to or receive a book from Paris, Brussels, or New York, that we are often obliged to abandon the attempt. The arrangements of booksellers and publishers do not provide against this state of things: they contemplate the sale of books of a particular class only. It therefore remains for journalists to make the facilities for transmission by post more available, by reducing the size and weight of their periodicals to the specified standard. Monthly journals might be made half-monthly, or even weekly, for foreign circulation, without any change except in the covers. With our editorial brethren in "the States" we are most anxious to cultivate a liberal coöperation, more for the sake of mutual improvement than for dollars or cents, which we know are as much esteemed at their side of the Atlantic as at ours; but in a transaction of this kind they are not much worth counting. Subscribers to contributing journals have a right to all the publicity which the press can afford, and when that publicity is limited by any petty pecuniary saving, or any little apprehension of competition, a wrong is inflicted. But we find that what we at first intended as a mere brief notice is running into an article on "Journalism;" upon which a long essay might be written, but which we are not at the present moment prepared to encounter. We may, however, take this opportunity to express our belief that notwithstanding the enormous expenditure of ink and paper, "medical literature," as in courtesy we are bound to call it, is not under the control of the soundest system. We are not claiming for ourselves any exemption from the sinister influences which mar its prospects; we only want to remind our brethren of the quill that it is time to think of these things. We cannot, we confess, congratulate them on the result of

present arrangements; for to say the truth, the "diffusion of useful knowledge" does not seem very apparent. In England the happy state of ignorance which prevails regarding the labours of contemporaries, notwithstanding the journalistic opportunities of the medical population, we often find to our amusement displayed in many of their "communications;" and this even more in the metropolis than in the provinces. In France it is much the same, but there the slight acquaintance with English and German possessed by the medical million must be accepted as an excuse; while in Scotland the free-and easy appropriation of other men's intellectual products must be attributed to a praiseworthy economy which forbids expenditure on book furniture. We would not for the world insinuate that the ignorance we speak of is in any case wilful, or lightly assumed to establish a character for originality; we only mention the matter *en passant*. There is, we admit, very often an astounding display of erudition in the shape of reference to authorities, but it is generally to Germans without surnames, title, or local habitation; or perhaps without any name at all, except some unpronounceable monosyllable. Our "authors" seem to be hand-and-glove with all of their own craft the world over, except those next door. In London we find many amiable exceptions, for there we find honest fellows who ignore everything beyond the sound of Bow-bells, and even rejoice to avow their ignorance of all things outside their own bounds.

OPERATION OF THE DISPENSARY ACT.

We find it very difficult to deal with the details of this measure at the present critical moment, lest we should do mischief in individual cases. Negotiations are now on foot more with the new Committees than with the Guardians or Commissioners, and these will require much tact and firmness to conclude successfully. We hear of some doings in these quarters, obviously illegal, and which therefore must prove null and void in the sequel; such as imposing conditions and requiring acquiescence in arrangements not contemplated by the act. Our advice has been, and still is, to secure a safe position just now, however unenviable it may be, and to improve it hereafter.

PAYMENT FOR MEDICAL SERVICES.

Since our last notice on this subject, we find the matter still attracting attention, as appears from the annexed extract. The subject is one requiring attention in Dublin as well as London, in consequence of the effects of recent changes of a pecuniary nature affecting our profession, which appear to tend to complications of a nature not likely to prove creditable or beneficial to its character. The Hospital Surgeons of Dublin heretofore have maintained a position which we would not without regret see damaged by any attempts to secure remuneration for services by unusual means:—

Your leading article of the 7th of February draws attention to a subject which may appear at first sight to possess only a "class" interest, whereas the welfare of the whole profession is deeply concerned in it. A proper remuneration to the assistant-physicians and surgeons of our hospitals and dispensaries is imperative if we wish the public to be imbued with a full and due appreciation of the value of medical services. You invite information as to those "public institutions in which this good rule (that of paying) prevails." I subjoin a list of them; also of those the committees and governors of which do not pay their medical officers. You perceive that among thirty-six institutions, twenty do not, and sixteen do, pay their medical officers; nearly a half are on the right side therefore. A better state of matters, really, than one expected, and raises hope that, "by a proper pressure from without," the responsible authorities of the remainder may quickly learn their true duty. It may be alleged that it is only a question of time and ability with the non-paying institutions, the governing bodies of which may be safely left to do that which is right in due season. It is not so; and deceived will the man be who tacitly awaits this consummation. Some may gracefully take the initiative, but the bulk will not advance until coerced. The suggestion of "S. P. R," in your number for 21st of February, is well worthy of notice, that a special fund should be created; but how long would it be before this could be brought into full operation? What a useless delay! when there are already, in many of the institutions, ample funds for the purpose. Let justice be done to the medical staff when the next call is made, in the usual coaxing language, "upon the benevolent public to enable the committee to extend the usefulness of the charity." The millionaires who sit at sundry of those boards would consider the man fit only for St. Luke's, who would seriously propose that porter, wine, gin, and viables, should be supplied gratis. Where is the difference, figuratively speaking, between their goods and the doctor's brains and time? The practice of medicine, above all other professions, involves the exercise of the highest order of charity. To seek out the sick bed of the retiring and impoverished gentlewoman, the decayed tradesman, and the still more to be pitied unsuccessful professional man, and administer relief and consolation, are legitimate objects to a medical man; but not to labour unrewarded, hazarding death and disease for years in the wards of hospitals, or in the still more sickly haunts of abject poverty. This is a work he owes not to the public, who ought not to call for its unpaid performance. The benefit is all to the public. He restores the sick child to support its aged parents; he gives renewed strength to the adult to procure food for his famishing family; he nurses the exhausted energies of the aged and rescues them from the workhouse. These are the wholesome results of his unpaid labour. The first and absolutely necessary step in the establishment of a medical charity is an efficient medical staff, and willingly have the members of the profession responded to such calls, and conscientiously perform the highest professional duties on a compact of honour. No other class of men would be asked or even trusted to act similarly in their several callings. Highly complimentary to us certainly, but compliments will not pay taxes or procure bread. No! that which may commence on a virtuous becomes a most vicious principle if carried beyond rational bounds. The general bodies of governors of those various institutions never can sanction the continued perpetration of injustice, and I look forward, with your help, to their calling upon the executives to terminate this intolerant evil.—*Letter in Lancet.*

Hospitals in which Assistant-Physicians and Surgeons receive Salaries.—St. Bartholomew's Hospital: Assistant-Physicians and Assistant-Surgeons, £100 each. Guy's Hospital: Assistant-Surgeons, £150. St. Thomas's Hospital: Assistant-Physician and Assistant-Surgeon, £50 each. Royal Free Hospital: Assistant-Surgeon, £100. Dreadnought Hospital: Assistant-Physician, £50; Assistant-Surgeon, £100. St. Luke's Hospital: Assistant-Physician, £100; Assistant-Surgeon, £50. Bethlem Hospital: Assistant-Physician, £150; Assistant-Surgeon, £60. London Fever Hospital: Assistant-Physician, £100. Small-pox Hospital: Assistant-Physician, £50. Bloomsbury Dispensary: Assistant-Physician and Assistant-Surgeon, £100 each. Tower Hamlets Dispensary: Assistant-Physician, £50; Assistant-Surgeon, £20. Surrey Dispensary: Assistant-Physician and Assistant-Surgeon, £40 each. Westminster Dispensary: Assistant-Physician and Assistant-Surgeon, £30 each. Finsbury Dispensary: Assistant-Physician and Assistant-Surgeon, £40 each. London Dispensary: Assistant-Physician and Assistant-Surgeon, £45 each.

Hospitals in which the Medical Officers are not paid.—London Hospital; St. George's Hospital; Middlesex Hospital; Westminster Hospital; King's College Hospital; University College Hospital; St. Mary's Hospital; Hospital for Consumption; Hospital for Women; Royal Infirmary for Diseases of the Chest; City of London Hospital for Diseases of the Chest; Newman-street Lying-in Institution; Orthopædic Hospital; Royal London Ophthalmic Hospital; Infirmary for Children; Blenheim-street Dispensary; City Dispensary; Farringdon Dispensary; Holloway and North Islington Dispensary; Islington Dispensary; Chelsea Dispensary; Northern Dispensary; Metropolitan Dispensary; Welbeck-street Dispensary. [We gladly publish the fore-

going lists, but we suspect our valued correspondent has made some error in limiting his figures to assistant-physicians and assistant-surgeons. It is likewise to be observed, that in some of the institutions named in the second list, the medical officers divide amongst them the fees of students. We shall be glad to see the subject fully investigated.—*Ed. L.*]

FRUITS OF HOMŒOPATHY.

I was requested, on Sunday, the 15th ult., to accompany a gentleman to see his wife, who, on my arrival, I found had just been delivered, prematurely, of a male child. On our way to his residence, he informed me that the medical gentleman engaged to attend her was so far distant from his home, that there was no time to gain his assistance; that he had been to request Mr. Duke, of Kennington, to come, who, he told me, usually acts for Dr. ——— ———, the homœopath, who was at the time in attendance upon her for an attack of jaundice; but he being absent from home, the husband came to me. Knowing the lady, I scarcely recognized her on entering the room, her skin was so much tinged with bile, she having, at the same time, a very anxious and depressed countenance, and feeling very weak. I tied the umbilical cord, separated the child from the mother, and in due time the placenta was expelled. There was no hæmorrhage. Having bandaged the abdomen, and made her as comfortable as I could, not being allowed to prescribe any medicine or nourishment for her, I left her, to be still under the charge of the globulistic professor, who saw her about two hours or so afterwards, ordered some rice-water and arrowroot-water, and administered some globules in person, as the nurse said she did know anything about his medicine. On the Thursday following, I accidentally heard that she died on the previous evening (three days after her confinement). On instituting an inquiry of the nurse, who is solely my informant, I find she was not allowed any nutritious diet till the Tuesday, and then, when it was allowed, she refused it. She gradually became more and more prostrated in strength, delirium supervened, the husband and friends became very anxious and alarmed, requested a second opinion, and then Mr. Duke met at the house Dr. ———, who, after this period, did not see the patient again alive, but left the case in charge of Mr. Duke, who commenced immediately giving brandy and yolk of eggs, ordering good nourishment, and drew off a large quantity of water; but it is evident all means were then useless, as death soon closed the scene.—*Letter in Lancet.*

It seems, then, that Hahnemann's globules do not prove a substitute for the accoucheur. What will Lord Fanny or Lady John say to this? Why should not an infinitesimal dose of ergot of rye do better than the common one? It is evident that this great discovery has not yet been thoroughly tested: a few more post-mortems will, however, probably throw light on the matter.

To Correspondents.—We refrain from publishing the note of L.R.C.S.I. for the present, because it might serve to counteract plans now under consideration to effect what he suggests. *Fas est ab hoste doceri*, and therefore do we think it prudent to observe caution, although we hold in reprobation the clandestine proceedings lately adopted in certain medical quarters.

NÆVUS TREATED BY TARTAR EMETIC.

Anne Shallard, aged nine months, was admitted into the the Queen's Hospital, Birmingham, under the care of Mr. Sands Cox, February, 1851, on account of a nævus situated over the right parietal bone, about the size of a half-crown piece. The mother stated that a slight discoloration of the scalp was observed at birth, that it remained stationary for some time, but eventually began to increase, and had during the last two months attained its present size. There was no pulsation evident in the tumour, which was of a bluish cast, and slightly raised above the adjoining integument. The child's general health was good, and all the functions regular; but a branch of the temporal artery was enlarged, and could be traced almost into the diseased parts. On the third day after admission, Mr. Sands Cox ordered the potassio-tartrate of antimony to be applied, which was accordingly done. In two days, the application having been several times repeated, the whole of the discoloured portion was converted into a pustular mass, and this with but little or no inflammation or irritation of the scalp. Poultices were now applied, and in the course of a week there was a healthy granulating surface, which was cicatrized entirely three weeks afterwards. For the cutaneous nævus pressure will sometimes succeed; and the continued application of collodion has, with small nævi, been followed by success. Nitrate of silver and caustic potash have also been used, likewise vaccination; all evidently acting in the same way as the tartar emetic—producing inflammation and suppuration, and thereby destroying the diseased texture. If, however, the nævus is of the subcutaneous kind, other methods must be had recourse to, and the ligature or knife then present themselves for use; but from the immense hæmorrhage which takes place if these tumours are cut into, the former is the most in vogue. If the knife is used, the rule laid down by Cooper should be adhered to—"Not to cut into the tumour, but to cut it out"—and the whole must be taken away, else what is left will certainly continue to grow as before.—*Prov. Jour.*

CEMENT FOR MENDING CHINA, Etc.

Take of isinglass two drachms, sprinkle it with water and allow it to stand until softened, then add as much proof spirit as will rather more than cover it, and dissolve with a moderate heat. Take of gum mastic one drachm, dissolve it in two or three drachms of rectified spirit. Mix the two solutions, and stir in one drachm of gum ammoniacum, previously reduced to fine powder and rubbed down with a little water. Evaporate, if necessary, in a water-bath to a proper consistence. Keep the cement in a bottle. When required for use plunge the bottle in warm water, and apply the cement with a stick or small hard brush to the china previously warmed. Compress the pieces firmly together until cold, taking care to make the contact perfect, and using a very thin layer of cement. When properly applied the cement is almost, if not quite, as strong as the china itself, unless exposed to the combined action of heat and moisture. Another cement, useful for many purposes, may be made by dissolving isinglass in glacial acetic acid and reducing it to the consistence of a thin jelly. It may be applied in the same manner as the above, but does not require to be warmed.—*Phar. Jr.*

ADJOURNMENT OF ELECTION.

ROSCREA UNION.

Roscrea Dispensary District.

THE Committee of Management of the Roscrea Dispensary District hereby give Notice that they will, at their Meeting to be held in Roscrea on Monday, 22nd of March instant, at eleven o'clock, proceed to elect

AN ASSISTANT MEDICAL OFFICER

for that District, at a salary of £45 per annum, under the provisions of the Medical Charities' Act, 14 and 15 Vic., c. 68. Sealed applications will be received by me up to ten o'clock on the above day. Candidates (with their testimonials) are required to be in attendance.

TIMOTHY BRIDGE,
Hon. Secretary to the Committee.

In consequence of a communication received from the Poor-law Commissioners, the above appointment is Adjourned until further notice.

TIMOTHY BRIDGE, Hon. Sec.

March 15, 1852.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

Just published, 8vo, pp. 96, price 2*s.* 6*d.*,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5*s.*,

THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

AN elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

Extracts and Editorial Note from the New York Journal of Medicine.

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,
"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,
"Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

SURGICAL SOCIETY OF IRELAND.—March 6.

Mr. TRANT, President of the College, in the chair.

ON THE ADULTERATIONS AND SUBSTITUTIONS OF MEDICINES.

By Sir JAMES MURRAY, M.D.

SIR JAMES MURRAY wished to call the attention of the Society to the very serious and alarming extent to which the adulteration and substitution of medicines was now being carried on in almost every part of the united kingdom. There were few places, of which he was aware, where anatomy and physiology were so well studied as in Dublin; but no science, however perfect, could enable medical men to cure the sick, unless the instruments with which they worked were pure and genuine. If he were to read a formal paper, he would have to recount hundreds—nay, thousands—of instances where he had known the lives of patients to be placed in imminent danger, either positively or negatively, by the substitution of one medicine for another—positively, by being in itself pernicious, or a preparation quite the reverse of what was indicated by the disease; and negatively, by depriving the sick of the advantages to be derived from suitable medicines or remedies of a proper quality. For example, there was nothing more common than to prescribe compound powder of jalap as a cooling purgative medicine, and to find afterwards that, instead of acting as had been expected, it had the effect of binding up the bowels in a very strange manner. The doctor then shook his head in silent astonishment, and drew the conclusion that the patient must have a very peculiar constitution. He cannot understand the reason of this torpidity of the bowels; but if he would analyse the medicine, he would find that instead of being made with jalap and cream of tartar, it was composed of alum and jalap, with a large proportion of the former. They might smile at this statement, but they would cease do so, if they read the valuable papers which had appeared in one of the London journals, during the last few months, in which the writer, Dr. Hassall, his friend and former pupil, had recorded adulterations of almost every article of diet, medicine, drink, and nourishment, which was sold in numberless shops in London. That gentleman had observed in adulterated articles of diet what he (Sir J. M.) was endeavouring to show to be the case with substituted articles of medicine. It was nearly useless for men to spend their lives in acquiring knowledge, if they were to be tripped up in their practice by not getting for their patients the genuine articles which they had ordered for them. Well, in another case, they might give Dover's powder—perhaps in diarrhœa, where there was extreme relaxation of the bowels—with the expectation that it would stay the inordinate condition of the alimentary canal; but they found that the more of it they gave, the more strongly it operated, and on examining the drug, it would be ascertained to be a powder, made up, not with ipecacuanha and opium, and a neutral salt to divide them, but of tartar emetic, rubbed up with some fine powder, like linseed meal. He now came to speak of a medicine which was much employed of late years, and he was induced to refer to it, because he happened to know a very simple mode of detecting its adulteration, and felt anxious to communicate the test everywhere. The medicine to which he alluded was cod-liver oil—a medicine frequently administered, and very deservedly, as almost an article of nutrition, when the powers of life were weak; and for the desirable object of making new blood and new flesh for the patient. Well, the physician, naturally enough, prescribed cod-liver oil, never dreaming that with an article of so moderate a price, there would be any attempt at a fraudulent substitution on the part of the party vending it. But he lamented to say that in several instances he had noticed that a vast deal of what was sold for cod-liver oil happened to be made up, partly of some whale or seal oil, with a great dash of linseed and plenty of rape oils, and not unfrequently some olive-oil, if they chanced to have a larger stock of the latter on their hands. Now, Mr. Donovan and others who had laboured so long to produce a good cod-liver oil, and with so much success, had all admitted that it was very difficult to detect the pure from the adulterated kinds. The pure oil was sometimes dis-

covered by its not coagulating with nitrate of mercury; and they had also detected the presence of vegetable oil by the effect of concentrated sulphuric acid, which did not produce the same result in the case of the vegetable, as it appeared to do in that of the animal oil. But occasionally it was no test at all, because the drug might contain a large quantity of the one or the other without being discoverable by sulphuric acid. About thirty years ago he observed at a cotton factory in Belfast, that when the proprietors got an animal oil, such as pure spermaceti oil, the spindles did not become green, as they invariably did when oil of a vegetable nature was employed in the factory; and that spermaceti oil was discoverable by its being specifically lighter than the vegetable oils. But it was discoverable in a much better way—namely, by its not clogging the spindles by forming a glutinous mucilage, as vegetable oils constantly did, and by the adhesiveness of this mucilage preventing the proper and complete lubrication of the spindles; whilst pure spermaceti oil, on the contrary, formed little or none of this mucilage, as they might reasonably suppose. The fact, however, which had led him to speak of testing cod-liver oil was this, that when pure spermaceti oil was long in use, in a warm factory, it did not form any salt of copper with the brasses of the machinery; whereas the vegetable oils, such as olive or rape, which were commonly substituted for the other, exhibited upon the machinery within a very short time a quantity of the salts of copper; so that any person who went into a cotton factory could tell whether the oil used in it was good or bad by observing whether the brasses were green or the contrary. By that observation he was led to see whether he could not distinguish pure cod-liver oil from the vegetable substitutions or mixtures sold in place of it, and it turned out just as he had expected; for on getting a little capsule of copper, large enough to hold a spoonful of pure cod liver oil (which he obtained from Mr. Donovan), and putting it on a sand-bath, he found that, no matter how long it was kept at a mild degree of heat, it exhibited no traces of copper salts; whereas all the spurious imitations of cod-liver oil, threw up a quantity of the salts of copper, forming a margin of green upon the disc of the copper vessel. This was the test to which he wished to direct attention, and it was far more easy and certain in its application than either sulphuric acid or the nitrate of mercury.

CASE OF UNUNITED FRACTURE OF THE HUMERUS.

Dr. Darby exhibited a specimen of ununited fracture of the humerus, taken from a patient whose arm he had removed the day previous. The patient, whose age was 52, had his arm broken by a blow of a winch in March, 1850; it was set in the usual manner by the surgeon who attended him. The bones not uniting within the usual time, he entered one of the Dublin hospitals in the July following, where he was salivated, and the limb put up in a starch bandage, but without any good result being produced. A seton was then introduced between the ends of the bones, but this step also failed to effect any decided improvement, and the poor fellow was sent away in the month of January unrelieved, after having been six months in the institution. He then entered the poorhouse which he (Dr. Darby) was in the habit of attending, and at this time the arm was hanging with a perfectly loose joint in the humerus. The man being anxious to submit to any operation likely to restore the use of his arm, he (Dr. Darby) determined to try the effect of excising the ends of the bones, which was accordingly done, but without any good result. The arm was then amputated at the patient's urgent desire. As far as he could discover, the man was not affected with either scrofula or venereal disease. He was a person of spare habit, but had all the outward appearances of a healthy labouring man, who had been accustomed to a country life, and had never suffered from any constitutional disease or defect whatever. The principal medicines employed in the case were iodine, phosphate of soda and lime, and cod-liver oil; none of which, however, seemed to produce any good effects.

EPIDEMIOLOGICAL SOCIETY.

Dr. Latham read a paper

ON THE EPIDEMICS OF THE SECOND, THIRD, AND SIXTH CENTURIES.

To the epidemics under the reigns of Antoninus and Decius, the notices of Niebuhr and Gibbon give considerable historical importance. Our knowledge, however, of their exact nature is by no means proportionate to our appreciation of their importance as political and social influences. In this respect they have been classed (by Niebuhr more especially) among the leading causes of the decline of the Roman empire. The extent to which the epidemics anterior to the reign of Aurelius Antoninus were true plagues, is uncertain. Niebuhr considers that they were not; but upon this point it must be remembered that the tendency to connect the plague of A.D. 167 with the return of the Roman armies from Persia, may have influenced criticism, and disposed inquirers to ignore the true Oriental character of previous pestilences. At any rate there is a notice of a pestilence and famine, attended by certain cosmic phenomena, in the reign of Trajan, with the significant addition that it was worse than the similar affliction in the time of Nerva—*i.e.*, the previous reign. Earthquakes, &c., are specially stated to have accompanied the plague of Antoninus: so they did that of Decius, about A.D. 270, or 100 years later. This seems to have been severer than the other, and to this a remarkable and well-known passage of Eusebius applies. It tells us, that the number of the recipients of public charity at Alexandria, "between the ages of 14 and 70, was not greater than the previous number of people between the ages of 40 and 70. Gibbon infers from this statement that above half of the inhabitants of Alexandria had perished, but the real proportion is nearly that of two to one, so that only one third of the population survived." *(Niebuhr).* In the reign of Diocletian there is a notice of a *peste* in Gaul; in that of Honorius, one of a *peste* in Rome, during its siege by the Goths (A.D. 408); in that of Julian and Constantine, of one at Armida. How far, however, these were true Oriental plagues, is uncertain. The Decian and Antonian epidemics are eminently unsatisfactory. The worthless writers of the *Augusta Historia*—neither cotemporary with the events they describe, nor capable of appreciating symptoms—are the chief authorities. In favourable contrast stands the plague of the sixth century, under Justinian: Procopius' description being full of medical facts. Sufferers when seized "became fevered of a sudden; some on waking, some whilst walking about, or on other business. The body changed nothing from its former colour; nor was it hot, as if under an attack of fever, nor was there inflammation. On the contrary, from the morning to the evening, the fever was so mild, that neither to the patient nor his physician, when touching him, were there any signs of its presence. Nor did any one of those thus attacked think that he could die. But afterwards, with some on the same day, with others the next, and several some days later, there rose a small bubo, not only in the lower part of the belly and the groin, but under the axilla, and with some behind the ears, and in other parts of the body. The disease began thus generally. The other symptoms varied with the individual. Some were seized with a deep coma, some with an acute frenzy. The frenzy was attended with sleeplessness and fancies, disturbance and cries. They threw themselves about into water (though not from thirst), struggled against food, and when no coma and no frenzy, the bubo wasted. With some it began in the head, when the eyes became bloodshot, and the face swelling, down to the throat. Some had diarrhœa, some buboes, and they died the third or second day, keeping their intellects. Some were mad; anthraces blinded others." To its non-contagious character, and to the inexplicable nature of its origin, Procopius strongly commits himself. It began in Egypt, reached Byzantium in the second year, and lasted four months. From writers of less importance we learn a few subsidiary facts—*e.g.* from Lyathias, that it returned more than once, that during its second visitation deaths were

chiefly from apoplexy, and that on the fifth day. Gregory of Tours indicates its bubonic character by calling it *morbus inguinalis*. Evagrius, who, unlike Procopius, was a strong contagionist, especially states that one and the same patient might be attacked by it a second time.—*Lancet*.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Dr. Gairdner read a paper

ON THE REGISTRATION OF CAUSES OF DEATH.

The object of the paper was to explain the principles followed by the author in the registration of deaths in connexion with the pathological department of the Royal Infirmary, and to endeavour to obtain the coöperation of the Society towards carrying out a more extended system of registration of deaths, on similar principles, founded on data contributed voluntarily by the medical profession in Edinburgh and Leith, and especially by the members of the Society. The author maintained, that many of the fallacies and imperfections of former systems of registration arose from the arbitrary limitations imposed upon practitioners in their statements of the cause of death, which was often much too complex to be with propriety registered under one, or even under two or three headings. The object of registration should be the concise statement of all the phenomena tending to produce the fatal event, in so far as they can be clearly ascertained, and subordinate phenomena, instead of being excluded from the register, or confounded with what might be regarded as the main disease, ought to be in all cases separately stated, with the view of securing correctness and uniformity, and of furnishing data for the investigation of the laws and combinations of disease. The nosological formulæ employed ought to be so contrived as to adapt themselves to every variety of information, the most general as well as the most detailed; and the registration of the same case under a variety of headings, instead of being regarded as an evil, should in reality have the effect of a check upon erroneous inferences. Many illustrations were given from the results of the Registrar-General's tables; and the author concluded by placing in the hands of the members copies of a draft of a nosological table, which he had drawn up for his own use in the Royal Infirmary.

Drs. Alison, Christison, and Andrew, agreed generally with the author of the paper in the principles he had maintained with respect to registration of deaths, and considered that the adoption of them would be an improvement on the methods of registration at present in use.

Dr. Christison remarked, that it was only due to the managers of the Royal Infirmary to state, that proposals regarding a correct system of registering the causes of death occurring in that institution had been frequently under the consideration of the board, and that they had even authorised a considerable expenditure of funds in endeavouring to establish improvements based on these proposals. He moved, that it be remitted to the council to appoint a committee on this subject to take into consideration the scheme of Dr. Gairdner, and to report to the Society at a future meeting. Seconded by Dr. Taylor, and carried unanimously.

CASE OF AXILLARY ANEURISM.

Dr. Mackenzie read the case of axillary aneurism which appeared in our February number.

Professor Miller remarked, that having heard the particulars of this case for the first time, he did not feel warranted in giving any definite opinion as to the nature of the tumour. Yet it seemed very plain that it could be but one of two things,—either a false aneurism by abscess, as in the case of Mr. Liston; or an ordinary spontaneous aneurism, whose sac had suppurated after deligation of the artery, and after some progress had been made towards cure of the aneurism; and he inclined to adopt the latter alternative, in consequence of pus having been found in the sac after death. He considered that an important point of pathology was connected with this question—namely, whether an unopened abscess has, or has not, the power of eroding a contiguous artery by ulceration. He had always maintained the affirmative, and very much on the following grounds:—1. *Open* abscesses, ulcerating in their walls, frequently erode *both arteries and veins*, causing formidable hæmorrhage, often fatal. 2. *Unopened* abscess has the power of eroding contiguous *vein*, as facts prove. Whence we might infer this—3. Unopened abscess perforates vein, but arterial tissue is more prone to ulceration than venous; therefore unopened abscess (*à fortiori*) may perforate a contiguous artery. 4. The evidence of facts,—some of them *prove* (1) that in the case of open abscess, with bleeding from a perforated artery, the erosion must have taken place *very soon* before the open state of the abscess was established; (2) while others equally *prove* that the perforation *had* occurred *during the occult condition* of the abscess, so constituting the Listonian form of false aneurism. These cases of the latter class he considered somewhat in detail; and among them one which had occurred in his own practice, in which false aneurism had followed perforation of the ulnar artery by abscess, and which case he had published in his Principles of Surgery. But of the series, perhaps the most conclusive were those related by Liston, Breschet, and Quain. He believed that it was thus demonstrable that the lesion in question does occur; the kind of abscess most likely to cause it being an acute abscess in the near vicinity of an artery, more especially when that vessel lies over the abscess, between it and the surface; or still more likely a chronic abscess, so situated, which in its growth has become acute—probably in a patient of debilitated frame. From this important fact in pathology, there emerged a still more important rule in practice—namely, the propriety of opening such an abscess *as soon as possible*, though yet deep and small, so that all chance of aneurismal erosion may be prevented, whilst at the same time the artery and wall of the abscess being not yet contiguous, there may be no risk of erosion and bleeding, in consequence of that ulceration of the abscess's wall, which so generally follows establishment of the open condition. As to the point of practice in the supposed case—of a Listonian false aneurism having been diagnosed during life,—he differed from Dr. Mackenzie. He preferred the Hunterian operation to the direct. In ordinary traumatic false aneurism—as at the bend of the arm—the direct operation was usually preferable; but then the artery was expected to be in all respects sound at the deligated parts, immediately above and below the aperture of communication with the sac. Here it is otherwise. From the nature of the case, it is to be expected that the patient, alarmed by new sensations and symptoms in the part, will anxiously seek the surgeon's aid very soon after perforation has occurred. The vessel at the eroded parts necessarily must be *inflamed* and *ulcerating*, and therefore in a most unsuitable frame for sustaining the ligature. This would come away prematurely, and secondary hæmorrhage would follow. Whereas by tying the vessel on the cardiac side, at a point sufficiently distant to avoid the inflamed disc, a vessel in all respects suited for deligation would be found, degenerated neither by chronic steatomatous change nor by acute inflammation. And while reasoning thus showed that such an operation might be *safer* than the direct, experience *proved* that this safer operation was quite *effectual* for the cure of ordinary false aneurism—and why not of this? The experience of the late Mr. Liston spoke plainly on this point.

Mr. Spence stated, that he felt no doubt as to the possibility of an artery communicating with the cavity of an abscess, in consequence of the ulceration of the vessel, and that he had always pointed out that in his surgical lectures as one of the dangers of neglected abscess in the neighbourhood of large vessels. There was one point which he thought had not been enough attended to by those who denied the likelihood of such an occurrence. They usually pointed to the fact of large arteries, exposed in sloughing ulcers, resisting the destructive action longer than any other texture, as an evidence of the arterial tissue being

possessed of a peculiar organization and vitality. Mr. S. on the other hand, held that vitality of the artery in such cases depended on the integrity of its peculiar vascular supply. When an artery is exposed in ulcer, the vessel and its sheath are still attached to, and receive nutrition from, the deep-seated parts. But the artery is in a very different position, when a portion of it is fairly insulated by purulent matter, as in the cavity of an abscess; for then the part of the arterial tissue so deprived of its vascular supply, will undergo the process of ulceration or slough as readily as other textures. In support of this opinion, Mr. S. showed a preparation from the University Museum (Catalogue, p. 77). The preparation showed the tonsil destroyed by an abscess, and external and inferior to it a large collection of pus, which had laid bare the great vessels and nerves below the angle of the jaw. The common carotid artery presented an ulcerated opening, near its termination; and there was another ulceration in the internal carotid, near its origin. The internal jugular vein was obliterated near the division of the common carotid. The patient a female, had suffered from swelling and pain at angle of jaw, and difficult deglutition, for some time. Two days before death she ejected some pus and blood from the mouth. Next day, the large abscess below the jaw was punctured with a lancet, when fœtid pus and sloughs were discharged; two hours afterwards arterial hæmorrhage occurred from the puncture, and recurred repeatedly during the day until evening, when the patient died. The abscess which had denuded the vessels having, in this case, been opened only two hours before the arterial hæmorrhage commenced, Mr. Spence thought there could be no reasonable doubt that the arterial tissue had been destroyed by the diseased action prior to the puncture of the abscess, though the slough had not then separated. No one could suppose that ulceration of the coats of the vessel had taken place in the short space of time between the opening of the abscess and the commencement of the bleeding.

Dr. Mackenzie said, that having noticed in the first part of his paper the repeated instances which were recorded of arteries having given way, by ulceration, into the cavities of abscesses which had been already opened, he had excluded all such cases, as not bearing directly on the point in question—viz., the formation of false aneurism by ulceration of the coats of an artery within the cavity of an unopened abscess. He was conversant with all the cases mentioned by Mr. Miller, but had avoided detaining the Society with an account of them, as he did not consider them analogous to his own case. On this account, too, he had only alluded very briefly to a similar lesion of the venous coats. Dr. M. had hoped his paper might have elicited further information on the subject from members of the Society, but it appeared, as far as he could find, that the three cases he had quoted from M. Robert (of Paris), Mr. Liston, and Mr. Quain (to which Mr. Dewes' case might probably be added), were the only cases in which this form of aneurism had been distinctly proved. Dr. M. was at a loss to understand how Mr. Miller could attribute the origin of the traumatic aneurism of the ulnar artery, to which he had alluded, to the previous formation of abscess. The woman had been stabbed a little below the bend of the arm, and an unsuccessful attempt had been made to secure the artery, which was wounded at a point extremely difficult of access. The hæmorrhage had recurred, and was arrested by compression. The wound healed, and the patient left the hospital, but returned in a short time with an aneurism at the seat of injury, on which Mr. Miller performed the usual operation for traumatic aneurism with success. Dr. M. could see nothing in this case to support the view Mr. Miller had taken of it. On the contrary, he considered the history of the case in every way to correspond with that of the usual formation of traumatic aneurism. As to the treatment of the form of aneurism produced by the communication of an artery with the cyst of an abscess, Dr. M. had only to repeat what he had already stated in the paper: he believed that were the character of such an aneurism recognized during life, the old operation would be more likely to be followed by a favourable result than the Hunterian operation. The prognosis was unfavourable under any circumstances; but he thought that the application of ligatures, a short way above and below the ulcerated opening in the artery, would probably be attended by less risk than the application of a single ligature on the cardiac side of the aneurism. The single ligature would not entirely arrest the flow into the aneurismal sac, and solidification of the tumour could not take place as in ordinary aneurism. Unless, then, the artery were obliterated in the neighbourhood of the ulcerated opening (an event which could not, in such a case, be looked for with any degree of certainty), hæmorrhage must inevitably ensue on the escape of the purulent contents of the cyst by a spontaneous or artificial opening on its surface.

Professor Miller said Dr. Mackenzie had objected to his (Mr. M.'s) explanation of the aneurism at the bend of the arm, in the example to which he had referred; and had mentioned that in that case bleeding had occurred some days after the application of the first ligatures by Mr. M. This bleeding, supposing it to have occurred, made no difference as to the theory of abscess causing aneurism. Dr. Mackenzie supposed that Prof. M. had omitted to tie the principal vessel, and that from it the bleeding in question took place. This supposition was both unlikely and unnecessary; unlikely, because the principal bleeding point was not likely to be overlooked in the free and thorough examination of the wound which was then made; unnecessary, because it was more probable that the bleeding took place from one or other of the vessels tied—these, inflamed and ulcerating, being obviously unsuitable for the plastic results after ligature. And this it was, doubtless, which had led Prof. M. as reported, to say, that thus it might be seen how Mr. Guthrie's practice was not always expedient: viz., that when the bleeding point was inflamed and ulcerating, it was better either to trust to graduated pressure on the part, or to tie the vessel at a Hunterian point. In the case in question, the features which favoured Mr. M.'s explanation were, the patient being discharged with a firm *depressed* cicatrix, signs of ordinary suppuration being reported in the narrative after dismissal, and in performing the ultimate operation the bleeding orifices being found lower than the part formerly tied. Those features had been untouched by the remarks of Dr. Mackenzie, and were strikingly corroborated by the analogous case in the *Lancet*. In Dr. Mackenzie's own case, it would not do to account for pus in the cyst after death, by supposing that the ligature of the subclavian had dried up the supply of blood, and that then the cyst had gone on secreting purulent matter uninterruptedly. For experiments on animals had demonstrated, that when even the largest vessels (in a state of health) were tied, free circulation was immediately restored on their distal aspect. And it was well known that after the Hunterian cure of aneurism by ligature, the sac continued for some time to be fully supplied with blood. Prof. M. still adhered to his opinion as to the treatment of a Listonian false aneurism if diagnosed during life—namely, ligature on the cardiac side. It was not inevitable that the sac should open. When the arterial perforation occurred, the case was thereby transferred from the category of abscess into that of aneurism, and was to be regarded and treated accordingly.

Dr. Gairdner said, that while he agreed with the other speakers in admitting the possible perforation of an unopened abscess into the canal of an artery, he thought that, in Mr. Liston's case, and perhaps in some of the others, the disappearance of the pus, and the absence of the local phenomena of its admixture with blood, were very inexplicable. Dr. H. Lee of London had lately pointed out, that whenever pus and blood came in contact, rapid coagulation of the latter was the result; this was invariable when the mixture was made out of the body, and yet there was no evidence of such coagulation having taken place in Mr. Liston's case, in which the pus, if ever present, must have been very thoroughly mixed up with the blood of the artery,

and might have been expected to produce coagulation either in the sac, or in the course of the circulation.

Professor MILLER said, the only explanatory circumstances he could state were the following:—The abscesses in question had been chronic, becoming secondarily acute, in patients of weak frame, consequently pus corpuscles would be few, and the contents would be mainly serum, and the gradual commixture of this fluid with living blood might be less formidable than the mingling of ordinary pus. In ordinary cases of pus-mingling, it was with the venous circulation; the pus, consequently, getting immediate and direct access to the heart and lungs;—whereas in these cases commixture was with arterial blood, and the pus could not reach these important parts without having previously passed through the systemic circulation, and become modified in character thereby.—*Monthly Journal.*

PHARMACEUTICAL SOCIETY.

Messrs. COFFEY and SMITH exhibited their steam apparatus for pharmaceutical purposes in full operation. This was, indeed, the most attractive object present, and ample opportunity was afforded for testing the practical working of the apparatus, and for criticising the different arrangements which Mr. Coffey has so ingeniously combined in a small compass. Some parts of the apparatus exhibited have been recently added, among which we may mention a contrivance, which was much admired, for stirring extracts and other liquids during the process of evaporation, a water-bath tunnel for filtering fatty or other substances requiring the application of heat to keep them liquid, a steam-saucepan for making decoctions, &c., and a vacuum pan which is worked with a solid-pistoned pump. Mr. Coffey has also recently constructed a gas furnace for heating crucibles of large size. Several gentlemen who were present, and are using Mr. Coffey's apparatus, expressed themselves perfectly satisfied with it.

Passing from this strictly pharmaceutical subject to one of more general interest, we may notice Mr. Shepherd's electro-magnetic clock, which was exhibited by the inventor and patentee. In this instrument electricity is the motive power which is substituted for the spring or weight of ordinary clocks, and it is said, with advantage in regard to the regularity of the action. But this is not the only advantage claimed in the application of electricity to time-pieces. Having one good time keeper, by connecting this by means of wires with any number of dials the same time will be indicated by all.

Some very powerful and beautifully finished steel magnets, made by M. Logemeat of Haarlem were exhibited by Mr. Knight of Foster-lane, the London agent. The first of these magnets shown in this country was exhibited some time ago by Mr. Faraday, at the Royal Institution, when he represented its power as nearly double that usually possessed by magnets of the same size. One of the magnets exhibited on the present occasion was capable of supporting nearly three hundred weight attached to the keeper.

Three very important improvements in the manufacture of flax and cotton were illustrated by a large number of specimens which covered one of the long tables in the lecture-room. The processes referred to are those respectively of the Chevallier Claussen, of Mr. Bower, and of Mr. Mercer. The old mode of preparing the flax for the use of the manufacturer consists in "rotting" the straw—that is, steeping it in water until decomposition of some of its constituents has been effected. Not only is this process objectionable on account of the offensive odour produced, but it is liable to frequent failure from circumstances over which the operator has but imperfect control.

Claussen's process consists in steeping the flax-straw in a weak solution of caustic alkali to fit it for the first preparation to which it is submitted, instead of leaving it to undergo spontaneous fermentation in water.

The Patent Wire Type Machine, which was in active operation, also attracted much attention. It had been furnished for the occasion by Mr. J. R. Johnson, one of the directors of the company, and M. Poirer, the inventor. The object of the invention is to produce printing type from copper, brass, zinc, and other hard metals, the letters being formed by a die, instead of being cast in a mould, as is now done with the comparatively soft type metal. A flattened wire, of the form and diameter of the type, on being passed through the machine, is cut into the proper lengths, and the required letter stamped at one end; and this is done so rapidly as to render the process a very economical one. Independently of the greater hardness of the metal used, as compared with that heretofore employed, it acquires increased hardness from the compression to which it is subjected, and the durability of the type, from these causes, is estimated to be sixty times greater than that of ordinary cast type. The letters are also more accurately formed.

Among machines having a more directly pharmaceutical application, there was one from Dr. Downing, called the *Aneuralgicon*, for applying warm medicinal vapours; and a feeding-bottle, called the single-tubed *Biberon*, from Dr. Ogier Ward. In this latter instrument the air only enters as the liquid contents of the bottle are withdrawn, and hence it is not liable to leak. We must not omit to notice also Mr. Stephen Green's anti-corrosian pump, for pumping oil of vitriol and other acids and liquids which act powerfully on metals. The pump is made of the brown stone-ware which Mr. Green manufactures into so many forms applicable for chemical and pharmaceutical purposes. Besides the above-named pump, there were exhibited, on the present occasion, stills, condensers, evaporating-pans, spherically-stoppered jars, percolators, tincture-jars, stop-cocks, &c., all made of the same material. The plan adopted in most of these cases of fitting the different parts of the apparatus together so as to form air-tight joints, by grinding spherical surfaces together, is particularly worthy of commendation.—*Phar. Jour.*

ON THE BILE.

By Dr. H. BENCE JONES, F.R.S.

THE bile has long been a subject of the greatest speculation on the part of physiologists, and there is scarcely any theory which has been advanced on the properties of the bile, which has not been defended by some writers. Dr. Jones compares it more to a kind of soap than anything else, and proceeds to inquire: What is the physiological action of the bile? The most opposite and the most important actions have been attributed to it. It has been said to promote digestion, and to stop digestion. Some say that it neutralizes free acid, thus lessening irritation; others, that it increases the peristaltic action of the bowels, thus increasing irritation. It has been said to be partly absorbed into the system to support respiration, by furnishing a highly carbonaceous body. Some have said that it promotes the absorption of fatty substances; and by others it has been said to have no action upon fats at all. To solve these questions was the difficulty. Experiments were tried by tying the common duct through which the bile passed; but this is not the way to arrive at a satisfactory result. If the bile is not suffered to pass, a stoppage is put to the functions of the liver; the whole order of the system is thrown out, and general disorder is produced. In 1844 a new mode of experimenting was begun by Schwann, who collected the bile without allowing it to pass into the intestines, by means of an opening similar to that which I mentioned in the case of the pancreatic duct. The action of the liver thus went on as usual, and all the functions of the body were performed without impediment. Twelve dogs lived from sixty-four to eighty days without any bile passing into the intestines; one dog, thus experimented upon, lived four months; and another, belonging, I believe, to M. Bernard, lived a year in this state. It was found that dogs thus treated ate much, and digested badly, partly in consequence of the unnatural fistulous opening. They did not lose much weight at first; but after a little time they lost their appetite, became thin, and ultimately died. The bowels acted as regularly and per-

fectly as if the bile had passed in the usual manner. Professor Nasse had a dog that lived from the 12th of August to the 27th of January. The quantity of bile varied with different kinds of food between 31 grains and 370 grains daily, with from 16.44 to 19.19 per cent. of solid constituents. Less was secreted when the dog was ill. The dog ate much, digested badly, did not lose weight at first, afterwards lost its appetite, and then became thin. M. Blondlot had a dog that flourished for three months. The bowels acted twice daily.*

Even in human subjects, it has been found that when a fistulous opening has been made, owing to perfect obstruction of the common duct, by inflammatory action, the bowels have continued to act when the bile did not pass—showing that the bile is by no means indispensable for their action.

Many experiments were tried with dogs, as to the quantity of bile secreted. The influence of medicine was also tried; and it is interesting to us to know that the action of mercury was decidedly to increase the quantity of bile secreted, as has long been held by medical men. If animals can live for a year, enjoy tolerable health, and digest their food, without any bile passing into the intestines, the importance of bile, and its necessity for the purposes of digestion have been exaggerated.

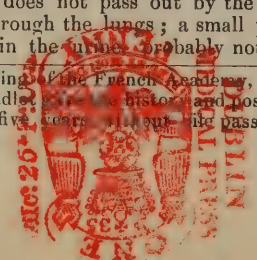
The action of bile out of the body on the different constituents of food, tends to precisely the same results as we have seen obtained by experiments in the body. Bile, when mixed with neutral fat or with oil, is found to have no chemical action whatever. It makes a sort of emulsion only, not quite so good as that produced by the pancreatic fluid. I added to solutions both of pancreatic juice and bile, equal quantities of water and oil, and then left them, after agitation for some time, to see which produced the most enduring emulsion. You see them here; both have caused the fatty matter to be minutely divided; but I think the pancreatic fluid has divided it and kept it divided the best. When fresh out of the body, bile has no action on starch; it does not change it into sugar, as we saw the saliva did. When, however, it is allowed to decompose, it has a slight action upon starch; but not more than all animal substances have. It has no action on cane-sugar until after it has stood for a considerable length of time, and then the cane-sugar is converted into acid. With grape-sugar, if left for any length of time, it forms lactic acid; but so do all other animal substances when in contact with sugar. It has no action, even when acidulated on casein, or on the albuminous substances which constitute our food.

It has been said that the liver purifies the blood by removing a large quantity of carbonaceous substance from it. To determine this by absolute experiment was a matter of great difficulty; but Schmidt has endeavoured to solve this question by experiments on forty cats, thirteen geese, many sheep and rabbits, in which he made fistulous openings into the gall-ducts for the purpose of collecting all the bile and of determining the proportion between the quantity of carbonic acid thrown out by the lungs and the quantity of carbon in the bile. He passed a tube into the gall-duct, and could measure how much gall came out per hour; and he could determine the composition of the bile by burning it and collecting the carbonic acid. He made, at the same time, comparative experiments on the respiration, some of which I shall have to detail to you in a future lecture; and he came to the conclusion that not more than from one-tenth to one-fortieth of the carbon which passes out of the body passes by the liver, and that therefore the liver has no considerable action in freeing the blood from carbonic acid or carbon. He found that eight-ninths or nine-tenths of the carbonaceous matter remains in the circulation, and does not pass out by the bile at all, but is thrown out through the lungs; a small portion, however, must escape in the urine, probably not much less than passes out in the bile. But I am unable to give you the proportion of carbon in the urine and bile daily excreted, from want of experiments.

What, then, in conclusion, are the uses of the bile? I have shown you that it is an alkaline fluid, and a body resembling soap. If soap is brought into contact with an acid, you know what happens; the alkali of the soap and the acid combine, and the acid of the soap is set free and precipitated. So also is it in the bile. If I take human bile, and mix it with acid (as you see in the experiment with sulphuric acid), a greenish white precipitate is formed. Let me show you what would happen to human bile if mixed with the acid secretion of the stomach. This I can do by adding dilute hydrochloric acid to a portion of bile, or better still by mixing some of the clear fluid obtained from the contents of the stomach, which I showed you in my lecture on the gastric juice; by both a precipitate will be immediately produced. The alkali which exists in the bile goes to the acid; it neutralizes so far, the acid reaction coming from the stomach; and it precipitates the insoluble acids, which give rise to choloidynic acid, and even to that still more insoluble substance, dyslysin, in its passage through the intestinal canal. It appears to me, then, that one great action of the bile is to furnish an alkaline fluid, which, when mixed with the acid secretion that has served the purpose of dissolving the albumen, will neutralize it, and lessen its acidity, so as to prevent it from producing irritation and increased action of the intestinal canal. That the stomach can actually bear much stronger acid than the bowels is known to most medical men. That the acid does not pass rapidly out of the stomach I am convinced by the following experiment:—To an adult man I gave 162 grains of dry, pure tartaric acid dissolved in two ounces of water. No pain was felt for three hours; no food was taken during this time; and without doubt, all the tartaric acid would in these three hours have been absorbed, or would have passed out of the stomach. At the end of this time, a pain in the bowels began to be felt, and at the end of the fourth hour there was very considerable pain, coming on in paroxysms. At the lapse of about five hours, if the bowels had been allowed to act, they would have acted from the acid thus taken. A repetition of the experiment, with 84 grains, gave precisely the same results. When the acid entered the bowels, pain began to be felt, and if bile in plenty had been poured out, the acid would have been neutralized, in part at least; the alkali would have combined with the acid; the insoluble bile acid would have been formed as a precipitate, and been thrown out of the body. If this be so, sluggishness of the liver, a deficiency of alkali poured into the duodenum, becomes a reasonable cause of excessive acidity of the intestines; the gastric acid required to dissolve the albuminous food, if sufficient bile is not formed, will pass into the intestines, and produce irritation and increased action. The physician has long held, that want of action of the liver gives rise to acidity, and that alterative medicines correct this state.

But the very great size which the liver attains in the fœtus appears to indicate that it performs some additional action independent of food and of digestion. This additional action has been said by German physiologists to be the reparation and the formation of blood globules; but this is by no means proved. It seems to me much more probable that it is for the purpose of neutralizing the acid, and probably also, for the purpose of removing, when requisite, some of the carbonaceous substances; in certain states compensating for the action of the lungs, though, in ordinary states, removing much less carbon than has been said. The bile gives water moreover to dilute the chyle; it tends to the subdivision, in some degree, of the fat and the oil of our food. It acts upon the free acid of the intestine; and some of it may be possibly absorbed, and pass into the circulation again, as Professor Liebig originally conjectured. It is not nearly so important as the gastric juice, which dissolves the albuminous part of our food, or the pancreatic fluid, and the salivary fluid, which convert all the insoluble starch, as I have shown you, into soluble

* At a meeting of the French Academy, on the 23rd of last June, M. Blondlot gave the history and post-mortem of a dog that lived for five years without bile passing into the intestines.



sugar. Lastly, the importance of the bile in forming sugar from fat, is one of those facts which cannot be overrated. By this discovery of M. Bernard's, very important knowledge relating to the physiology and pathology of man will be obtained during the next few years; at least there can be little doubt, that the disease known as diabetes, if not closely connected with this production of sugar in the liver, must at least be influenced by it to a very considerable extent.—*Medical Times*.

CASE IN WHICH THIRTY-SIX OUNCES OF CHLOROFORM WAS USED IN FOURTEEN DAYS.

By W. H. Byford, M.D.,
Professor of Anatomy, Evansville Medical College, U.S.

Believing that the following case is rather uncommon, from the amount of chloroform which was taken, and the entire immunity from any ill effect resulting from its use, I am induced to send it to you for publication.

The subject was a young lady, aged 18 years. About six years since, her friends discovered an angular curvature of the spinal column, resulting from caries of the two upper lumbar vertebræ. Previous to the discovery of this abnormal condition of the spine, for some months, she had been suffering from excessive pains in the lower extremities, and halting in her gait.

For upwards of a year, these symptoms continued, when they wore off. During this time, the curvature made its appearance. After a time, the vertebral column became solid, and she experienced but little inconvenience from it save the consciousness of deformity. Every few months since that time, she has had an attack of fever, accompanied with pain in the epigastric region, radiating to the shoulders and down the arms, vomiting, and obstinate costiveness. In one of these paroxysms, one of her arms was temporarily paralyzed and did not regain the power of motion until after she had recovered completely from the other symptoms. The treatment employed at such times, consisted of bleeding, cathartics, calomel, and morphia, blistering, &c., under the use of which remedies, the attacks would last for from one to three weeks. During the month of February last, the disease returned with more than its usual violence. On the fifth day, I was called to see her. She was then vomiting frequently, had had no alvine evacuation for four days previous; complained of lancinating pain in the epigastrium, shooting up into the shoulders, down the arms, around the abdomen, pain down the legs, in fact, all over the system where it is supplied with spinal nerves, with irregular contractions of the whole voluntary muscular system. She had been taking large doses of morphia to no good effect, it not having procured sleep or even rest. Her suffering was so great, that her cries might have been heard for some distance day and night. I bled her largely twice in a short time; gave her a cathartic of colomel followed by senna and salts; used strong liniments to the spine, and a blister to the epigastrium; warm pediluvia, &c. After which I again resorted to morphia, but without relief. On the eighth day from the onset of the attack, I commenced the use of chloroform, giving thirty drops on a silk handkerchief to respire, which produced almost immediate ease. In a few moments, however, the pains returned, and again were subdued by this agent. She was now kept under its influence for about an hour, after which she continued to sleep for three hours without its reapplication. At the end of this time, she awoke screaming with pain. Mr. Egleston, a medical student, now gave the chloroform, when she became quiet for an hour, or longer. After taking it for several times in this way, its influence became less, lasting but a very short time only, when the pains would return again with great violence. In this manner she was nearly constantly taking it for fourteen days, during which time she used not less than thirty-six ounces. A part of this quantity of course must have been dissipated by evaporation, that was not inhaled, but certainly not more than is lost in its administration generally. Under its influence, however, at last, this paroxysm gradually wore off, and the patient is now enjoying her usual health, which, to a casual observer, would seem perfect. No permanent effect, so far as I can ascertain, followed the administration of this, I may say, excessive amount of this powerful agent. On the contrary, the convalescence was uninterrupted, rapid, and apparently complete. It may be interesting to make some remarks as to its effects upon the circulation and respiratory organs. The pulse was always lessened in number and force, but in this instance, it was never reduced below the natural standard. The lungs were more affected: a mild degree of bronchitis having been produced, as I thought as the result of its use, which continued the whole time of its administration, but gradually and readily subsided upon its withdrawal. The number of respiratory efforts were diminished in about the same proportion as the action of the arteries was reduced. Upon the nervous system no other perceptible effects were observed than entire ease and quietude, approaching natural repose. I am led, from reflecting upon this and some other cases in which I have seen chloroform used, to believe that in estimating the beneficial or injurious influences likely to be exerted by this powerful medicine, our attention has not been sufficiently directed to the *condition* of the *nervous* system, particularly in regard to the presence or absence of pain, or other preternatural excitement. I apprehend that we will find the same laws governing our physical system, to obtain with respect to its use, as we are compelled to take into account, when we call to our aid any of the powerful narcotics, one of which is, the preservation, in a great measure, of the general system, by the nervous system being pre-occupied by exalted or morbid excitement. This principle may account for the fact, borne out, I think, by statistics upon the subject, that the untoward and melancholy effects of chloroform, seldom, if ever, occur in cases where the system is labouring under great pain, as for instance, labour, toothache, &c.

Those more conversant than myself with the numerous facts in connexion with this subject, will be competent to judge of the correctness of this conclusion. If it be true that pain ensures immunity from the deleterious effects in these cases, we may yet hope, by not commencing too soon in surgical cases, to afford our patients all the good, without incurring risk from the evil influences of it. Following up this idea, we would not wait to commence the use of the knife until the patient was entirely under its influence.—*Amer. Jour. of Med. Sci.*

OPERATION FOR OVARIAN DROPSY.

By Mr. I. B. Brown of St. Mary's Hospital.

A certain amount of excitement has been existing for a little time past regarding the operation which we are going to describe. It was by some supposed that Mr. Brown intended to remove the cyst completely, but it soon became known that a somewhat new line of practice would be adopted, which consisted in the removal of a small portion of the cyst, after the evacuation of the fluid. The theatre was crowded, and Mr. Brown, before the patient was brought in, stated that the cyst in the present case was very thin, and that he would excise a portion of it, after tapping, and leave the fluids, furthermore secreted, to be expelled by other channels. Mr. Brown was likewise anxious to explain why he did not, in the present instance, use pressure, as he had successfully done in many other cases. The reason was, that the patient is the subject of prolapsus uteri, and that any compression over the hypogastrium must necessarily render the displacement greater, and force the organ out of the vagina. The patient is a woman about 40, following the occupation of servant, and who has been suffering from ovarian dropsy for several years past. She had spent some time in another hospital, whence she was discharged as incurable, being told that tapping would be of no benefit to her; she therefore now objected to this ordinary means of removing the fluid.

Chloroform was administered by Dr. Snow, first with

his inhaler, and afterwards with the simple sponge, the insensibility remaining complete all through the operation. The patient's abdomen is very prominent and pendulous, the skin being of rather a dark tinge, and permeated with large veins. Mr. Brown made his incision in the mesial line, commencing a little below the umbilicus, and descending in a straight direction for about four inches. All the layers down to the peritoneum were carefully divided, and the latter slit open with the assistance of the director. The cyst, of a light grey colour, now came into view, bulged out by the fluid; and Mr. Brown passed his finger easily between the cyst and parietes of the abdomen. It was now plain that no adhesions existed between these parts, for the whole hand of the operator was easily glided all round the cyst, between the latter and the walls of the abdomen. It struck some of the spectators that this great freedom from adhesions, might perhaps be favourable to the complete removal of the cyst. Mr. Brown now introduced the trocar and canula in the centre of the exposed portion of the cyst, and evacuated about a gallon of very clear limpid fluid, the cyst being all this while held by an assistant with a vulsellum, so as to prevent its collapse. After the removal of the fluid, Mr. Brown raised, with the vulsellum, a portion of the cyst about the size of the palm of the hand, and removed it by a horizontal section with the scalpel. A little fluid which had collected during this process was now allowed to escape, and the cyst pushed back into the abdomen. The margins of the cutaneous section were brought together and secured by six sutures, a compress applied, and a wide roller placed around the abdomen. Very little blood was lost during the operation, and none at all on the section of the cyst.

When the patient was removed, Mr. Brown addressed the gentlemen present, and stated that his reason for adopting this line of practice was, that cysts which spontaneously burst have been known to give patients no further uneasiness, the fluid being probably, after the collapse of the cyst, taken up by the absorbents. He cited the case of a lady who had been under the care of Dr. Henry Davies, and with whom such spontaneous bursting and collapse had taken place. The lady experienced no further ovarian annoyance, and died ten years afterwards of another disease. On a post-mortem examination, made by Mr. Brown, it was found that the cyst had completely shrunk, and that an aperture of some size existed in it, probably where the cyst had formerly burst. The preparation is preserved in the museum of St. George's Hospital. Mr. Brown considered the present operation far less dangerous than ovariotomy, and he did not apprehend any mischief from the opening of the peritoneum, as he had made incisions into that membrane in many cases before, for various purposes, without any untoward results. Mr. Brown had had under his care a very old lady, affected with a multilocular ovarian cyst. She was treated in this manner; one of the numerous cysts collapsed, and gave no further uneasiness. This treatment was not, however, pursued, on account of the lady's great age. But it might be expected that more success would be obtained in the present case, where the cyst is probably of the single kind. We shall watch this case with much interest, and acquaint our readers with its progress.—*Lancet.*

TREATMENT OF BRONCHOCELE BY COMPRESSION.

By Dr. Dwight, Moscow, United States.

The author having frequently failed with iodine, and further having met with cases in which injurious effects were supposed to have been produced by that medicine, was induced to try the effects of pressure, which he accomplished in the following manner:—

Three straps of glazed cambric were spread with adhesive plaster, each half the width of the tumour, and sufficiently long to reach from the lower edge of the scapula of one side obliquely up the opposite side of the neck and across the lower part of the tumour, passing thence onward in return to the upward direction down to the lower edge of the opposite scapula, crossing like suspenders. The strap is drawn quite tightly, producing very considerable turgescence of the bloodvessels of the face. The patient will shrug up his shoulders for a few minutes until the thyroid vessels become compressed sufficiently to enable him to breathe more comfortably, and the countenance resumes its natural appearance. Five minutes is all the time ordinarily required. The second strap is then passed in the same manner across the upper part, from half an inch to an inch from the first, according to the circumstances of the case, such as length of neck, size of tumour, or situation and form. This strap is drawn as tightly as the first. After waiting until the countenance allows a new application, the third strap is put on in the same manner over the immediate space in like fashion.

Ordinarily the plasters will adhere in cool weather from ten days to a fortnight, when, becoming loose and non-adherent, they ought to be removed. If the pressure has been well applied, the tumour will be found to have become slightly less, the skin somewhat reddened and tender. In such case it is prudent to wait until it assumes its natural appearance before a new application of the plasters.

The first application has in one case been sufficient; but the average has been as high as four times in each case. When the bronchocele has become diminished to half its size at the time of its first application, it will continue to disappear without further care. The author states that the success which has attended this treatment is such as to warrant confidence. In twenty cases there has been no failure. In the first four, iodine was used in conjunction with the plasters, and in the twelfth it was used antecedently for several weeks without diminution of the disease. In these cases the progress was no more rapid than when no iodine was used. In two of the cases the disease returned at the end of two years each, but on a new application of the straps was immediately overcome; and although ten years have elapsed since the last application, all is as well as though there had never been any deformity. It is proper to add, also, that in both of these cases iodine was freely taken, as well as pressure used at the commencement.—*North-Western Med. and Sur. Jour.*

ON QUINIDINE.

By Mr. Robert Howard.

This alkaloid, which gained a prize in the great exhibition, has scarcely yet attracted much attention. Some of the cheaper barks now largely imported from New Grenada contain so much of it that it is, perhaps, as well that it should be more studied. The *Cinchona cordifolia*, from that part of the continent, is particularly rich in it. It is, however, contained in larger or smaller quantities in the Bolivian and Peruvian barks—the *Cinchona*, *Calisaya*, *Boliviana*, *rufinervis*, and especially *ovata*.

The sulphate of quinidine is so like the sulphate of quinine, that the eye or the taste can with difficulty distinguish them. It forms the same light fibrous crystallization, and occupies as large a bulk. It corresponds in appearance with the description given by Winckler, of "chinidine." He notices that it has "a remarkably white colour and a peculiarly faint lustre." Its most striking characteristic is its extreme solubility. Pure sulphate of quinine requires nearly thirty times its weight of boiling water for solution, whilst the sulphate of quinidine dissolves in four parts. On the other hand, the pure alkaloid crystallizes readily out of proof spirit and out of ether, whilst quinine does not crystallize out of either. A very good test for the presence of cinchonine in sulphate of quinine is also capable of being applied to detect the presence of quinine. On this point I would refer for very interesting details to a paper by M. Guibourt, in the *Journal de Pharmacie* for January in this year.

In your journal of April, 1843, I gave a test for sulphate of quinine, to which I would again advert, because subsequent experience has proved it to be a tolerably easy, and at the same time exact means of ascertaining its purity. Put 100 grains in a Florence flask with five ounces of dis-

tilled water, heat this to brisk ebullition; the sulphate of quinine ought not to be entirely dissolved; add two ounces more water, and again heat it to ebullition; ought to make a perfectly clear solution. If this be allowed to cool for six hours, and the crystals carefully dried in the open air on blotting paper, they will be found to weigh about ninety grains, the mother-liquor may be evaporated and tested with ether, when any cinchonine or quinine will be easily detected. On examining sulphate of quinine of commerce from several leading manufacturers, I have found all of them give, within a grain or two, the same result, and in each indications of quinine, though to an unimportant extent.

The above quantity of water (seven ounces) readily dissolves 800 grains of sulphate of quinine; and if 100 grains of this salt are dissolved in seven ounces of water, the crystals dried as above weigh only fifty-four grains, thus leaving forty-six grains in solution instead of about ten grains. The medicinal effects of B quinine deserve investigation, the chemical constitution and the taste appear to indicate a great similarity if not identity.—*Phar. Jour.*

EMPHYSEMA OCCURRING DURING LABOUR.

By L. S. Joynes, M.D., of Accomack, Virginia, U.S.

In a late number of the *American Journal* was published a case of emphysema of the cellular tissue occurring during difficult labour. The perusal of this case, reported by Dr. Abbot, brought to my mind an instance of the same accident which once fell under my own observation; and the extreme rarity of its occurrence, as well as the silence of nearly all our standard obstetrical authors concerning it, induces me to send you a brief statement of the case which I witnessed. It occurred in the Dublin Lying-in Hospital, in the summer of 1842, while I was a resident pupil of that institution. I give the report of it nearly *verbatim* from notes taken at the time.

Emphysema of the Cellular Tissue occurring during Labour.—This was a first confinement; the first stage being very tedious, some tartar emetic was administered, according to the practice of the hospital, with the view of bringing about relaxation of the *os uteri*. The second stage was more rapid; just as the child's head was beginning to press upon the perineum, the patient's face and neck were observed to swell, and she complained of some tightness of the respiration. The face, neck, chest, and arms, almost to the hands, were found to crepitate upon pressure, and the sides of the neck were resonant on percussion; there was tenderness on pressure above the clavicle. The patient was immediately bled to ʒxx., and being soon delivered (by the natural efforts), the farther increase of the effusion of air was prevented. Had the child not been soon expelled it was the intention of Dr. Johnson to apply the forceps. Auscultation and percussion of the thorax revealed nothing abnormal, so that there was clearly no effusion of air into the pleura. The patient slept as soundly during the night as if nothing had happened. Her recovery was in every way favourable; she left the hospital on the ninth day, the swelling having then entirely disappeared, and with it the tenderness above the clavicle. Dr. Johnson says that he has always observed a favourable termination in the cases of this accident which he has met with, but he always takes the precaution of bleeding the patient, with the view of guarding against inflammation of the lungs, as there must evidently be a solution of continuity at some point of its surface, in all probability at its root.

The gentleman whose opinion is here quoted, is Dr. C. Johnson of Dublin, at that time master, or accoucheur-in-chief of the hospital, a man of large experience and high reputation in Dublin. His explanation of the accident in question differs in some degree from that given by Drs. Blundell and Abbot, in fixing the probable seat of rupture at the root of the lung, whence the effused air escapes between the reflections of the pleura into the cellular tissues of the mediastinum, thence into the neck, &c. This explanation would appear the more plausible of the two, though this is, at best, matter of speculation.—*Amer. Jr.*

TREATMENT OF MAMMARY ABSCESS BY COLLODION.

By Dr. Evans, United States.

Mammary inflammation, during lactation, is exceedingly prone to end in abscess. This is owing to the great vascularity of the organ, and its loose and flaccid texture, which allows the determination of blood to it speedily to result in effusion of lymph, which, in the absence of the pressure made by denser structures, is not absorbed, but results in the secretion of pus. Thus when the breast becomes indurated under the treatment heretofore practised by the profession, of poulticing, applying liniments, tobacco leaves, &c., without constitutional treatment, it almost uniformly forms an abscess. Disheartened by the general want of success in preventing suppuration by the ordinary means of treatment, and satisfied that the most prominent indication of cure was to overcome the freedom with which the blood is forced into the mamma, and, by compression, cause the absorption of the lymph, as is done by the roller applied on the extremities, in various forms of inflammation, Dr. Evans determined to use a complete coating of the collodion to obtain the benefit of its contraction; the result of which will be more fully illustrated by relating the following cases in which it has been used:—

Case 1.—December 18, 1849. Called to see Mrs. J., suffering from mammary inflammation during lactation; found she bathed with liniments, applied poultices, and kept the milk well drawn from the breasts, but without apparent benefit; I could detect decided fluctuation at the point of greatest suffering; I ordered a coat of the liquid adhesive plaster, which gave very prompt relief, and the inflammation speedily subsided; a few days after I opened the abscess, which pointed, but it discharged a very small quantity and rapidly recovered.

Case 2.—Mrs. S. was confined June 5, 1850, with her third child. On the 7th she was attacked with a chill, followed by high fever and active inflammation of both mammæ; she had suffered after each of her previous confinements, with extensive abscess of the left breast; the secretion of milk was very profuse; and notwithstanding strenuous efforts to keep the milk drawn off by the assistance of a little girl, who drew it very freely, the left mammæ became extensively indurated, and was acutely sensitive and painful at the point of the former abscesses. I applied the collodion so as to cover the indurations completely, with the effect of promptly relieving the suffering of the patient; and by repeating the coating morning and night for a few days, the indurations were removed; the only additional treatment used was seidlitz powders, given to produce a laxative effect.

Case 3.—Mrs. McC., eight days after confinement, was attacked with mammary inflammation, attended with chill and high febrile excitement, on the 8th of June, 1850. Gave mass. hyd. grs. xij., with pulv. Doveri, grs. viij., in the evening. June 9th. The breast is very painful, and extremely tender to the touch, great thirst, dry mouth, frequent but compressible pulse, and a troublesome cough; the bowels had not been moved. Ordered sol. mag., oz. ss., and an application of the collodion to the breast, and free abstraction of milk. June 10th. Much better; says the application of collodion to the inflamed breast gave immediate relief to the pain, and the soreness has rapidly diminished; ordered the application to be repeated; the recovery was rapid without suppuration.

Case 4.—Mrs. P., three weeks after confinement, was attacked with inflammation of the mamma on the 24th of June, 1840; she had been previously under treatment for uterine phlebitis, from which she was recovering. The breast was swollen, indurated, and very painful; the collodion was applied so as to cover the induration and swelling, with almost instant relief to the pain; by repeating the application the swelling subsided gradually, without suppuration.

Case 5.—July 15, 1850. Mrs. M. had an attack of inflammation of the right mamma, about ten days after confinement; I was called the next day and found it

swollen, indurated, and painful, notwithstanding the milk had been kept freely drawn, and the breast well fomented; a coating of collodion, as in the preceding cases, promptly gave relief to the pain, and gradually removed the swelling; in no case where I have used the collodion, except the first one reported, has the slightest suppuration taken place; in every instance the relief from suffering has been prompt, and no inconvenience has resulted from its use in any case, except the slight smarting that attends its application.—*Western Med. Jour.*

DISLOCATION OF THE THUMB.

M. Demarquay has published in the *Bulletin de Thérapeutique* certain experiments of his which were undertaken to ascertain the actual state of parts in luxation of the thumb. The case which directed M. Demarquay's attention to the subject is the following:—A lady, in leaving her carriage, fell upon the pavement, with outstretched arms, and a dislocation of the thumb ensued. M. Demarquay thus describes the state of the parts. The thumb was forced backwards, and formed an obtuse angle with the corresponding metacarpal bone, whose phalangeal articulation projected under the muscles of the thumb. The ungual phalanx was flexed, and all movements of further flexion or extension were impossible. M. Demarquay used all known means of reduction without success, and M. Roux was called in previous to muscular section. The latter surgeon used the same tractions as had before been done; but before flexing the thumb he rotated it inwards, whilst he made forcible flexion, and reduction was thus obtained.

M. Demarquay was struck with this result. He made several experiments on the subject, and found that in a complete luxation of the thumb backwards, the following changes take place. The metacarpal extremity of the first phalanx comes to rest on the posterior portion of the articular surface of the first metacarpal bone; and the phalangeal extremity of the latter projects under the skin, after having passed through the two portions of the flexor brevis pollicis, the external portion being frequently torn. This phalangeal extremity of the first metacarpal bone is thus caught in a loop formed externally by the outer part of the flexor brevis and the abductor, and internally by the inner portion of flexor brevis, the adductor pollicis, and the strong tendon of the flexor longus pollicis. That these are really the phenomena which take place has been ascertained by the experiments of Messrs. Pailloux, Vidal, Malgaigne, Lisfranc, and Laurie. Inspections of individuals who have died with this luxation, have shown besides that the anterior ligament is always ruptured close to the metacarpal bone, and that it is carried along with the posterior portion of the luxated first phalanx. As in the above mentioned experiments both lateral ligaments, or at least the external, were always ruptured, the theory of Dupuytren and Rey falls to the ground. If, then, the difficulty of reduction cannot be ascribed to the persistence of the lateral ligaments, nor to the force of the anterior ligament, the main obstacle must lie in the muscular loop, which is slung round the head of the metacarpal bone.

In summing up, M. Demarquay gives the following rules:—1. To use a sufficient amount of traction (with Charrière's forceps) on the luxated bone, in the direction of the axis of the thumb. 2. To push back with the operator's thumb, or left index finger, the head of the metacarpal bone, and keep it quite steady, so that when flexion is made, the head may not be thrust further into the palm of the hand. 3. When extension is carried to a sufficient extent, rotation either towards the outer or inner side should be made, so that the head of the metacarpal bone may be freed from the muscular loop which is keeping it strangulated. This being done, the traction should be continued until the posterior part of the first phalanx has reached the level of the head of the metacarpal bone. Flexion is then to be made, whilst at the same time the left thumb of the operator forces backwards the displaced part of the first metacarpal bone.—*Lancet.*

STYPTIC POWERS OF MATICO IN UTERINE HÆMORRHAGE.

Mr. Giraud relates the following case, in which the local application of matico proved successful in restraining severe uterine hæmorrhage. The patient was a woman aged 37, the mother of ten children. Since the birth of her last child, sixteen months since, she has been subject to uterine hæmorrhage at uncertain intervals. On examination the os uteri was found to be irregular, having an ulcerated surface, with hard edges, occupying one-third of its circumference. In spite of the recumbent posture, and the injection of a strong solution of nitrate of silver three times a day, several napkins continued to be soaked with blood during the night and day for ten or fourteen days, and the patient began to evince the usual symptoms of chronic hæmorrhage. A paste of matico leaves was then made, mixed with a little mucilage of acacia, and having rolled it into balls of a convenient size, three or four of them were introduced into the vagina, and kept in contact with the os uteri by a firm plug of lint, completely filling up the vagina. No pain or inconvenience from this application was experienced, and the bleeding ceased entirely, and it was not renewed after the plug and matico came away at the end of ten days. Although the os uteri continued much in the same state, and there was too much reason to fear that malignant disease existed, the author states that the effect of the application of matico in this case increases his confidence in its styptic power, and has made him determine on using it, in this same form of paste, in the troublesome hæmorrhage which occurs from carcinomatous and other unmanageable ulcerative surfaces.—*Prov. Jour.*

OVER-DOSE OF LIQUOR AMMONIÆ.

P. W——, aged 36, a conductor, was admitted into St. Mary's Hospital, under the care of Dr. Alderson, at twelve p.m., February 22, 1852, having an hour previously taken an ounce of hartshorn, which in the dark he had mixed with milk, in mistake for castor oil. He said that he swallowed it all, having, as was his custom on taking any of the oil, "gulphed it down." On finding his mistake he took copious draughts of warm water, when he vomited a quantity of matter like soap-suds, but continuing to suffer great pain, he was advised to come to the hospital, when on examination the inside of his upper lip, tongue, roof of mouth, and fauces, were white, and other parts excoriated; there was great difficulty in swallowing, and he said he felt as if he was on fire from his stomach to his mouth; voice husky; pulse small, 112; surface rather cold. He was ordered dilute acetic acid, and then a mixture consisting of equal parts of olive oil and mucilage; an ounce for a dose. 23rd. Pulse 108; coughed and retched several times during the night; says he experienced much relief from the oily mixture. There was severe pain over the epigastric region, increased by pressure, with the same burning sensation from the stomach to the mouth. Was ordered a cooling gargle, demulcent drinks, and some leeches to the epigastrium. 24th. Felt more comfortable, and had much less pain; pulse 94. He did not require any further treatment, and left the hospital on the 27th, when the voice had regained its natural tone. There was not any diarrhœa throughout the case. The speedy recovery, I think it fair to suppose, was much aided by the nature of the liquid in which the hartshorn was taken.—*Mr. Trotter in Lancet.*

The "hartshorn" in this case was, we conclude, *liquor ammoniæ* of unknown strength. It seems to have been just sufficiently alkaline to soften or dissolve the epidermis or cuticle, but not to kill the living surface of the mucous membrane of the mouth and œsophagus. The speedy recovery of the lining membrane of the stomach after such stimulation is instructive, considered in connexion with a question as to the therapeutic value of this agent, so often indiscriminately administered.

NÆVUS CURED BY VACCINATION.

By Mr. Woolcott,
Surgeon to the Kent Ophthalmic Hospital.

A lady brought to me her infant, a healthy-looking child, nine weeks old, in January, 1848, with an extensive subcutaneous nævus, which had existed from birth. The tumour, which was of a blue, livid colour, occupied the whole of the upper eyelid and a small portion of the root of the nose on the right side, and extended upwards upon the brow and forehead as high as the upper border of the orbicularis palpebrarum muscle; outwards and downwards it reached nearly to the tragus of the right ear, and then extended upwards and inwards along the lower margin of the zygomatic process of the temporal bone, across the malar bone to the external angle of the orbit, where it joined the morbid product at the upper eyelid; there was no pulsation in the tumour; it was soft and compressible, and increased greatly when the child cried, and it then assumed a dark purple colour; pressure on the temporal arteries did not diminish its bulk. The application of ligatures in this case was of course inadmissible, on account of the deformity which would arise from cicatrization of the wound causing ectropium. The treatment for the first month consisted in the application of tincture of iodine, the abnormal growth being freely punctured all over with a fine cataract needle, and the iodine applied over the punctures. The bleeding was considerable, and of arterial character, but it soon subsided on the application of the iodine. These punctures were made twice a week, but the iodine was applied daily, except when it caused too great irritation and soreness of the skin, when it was discontinued for a day or two, and then resumed. At the end of the month, the disease remaining undiminished, I altered the treatment and applied vaccine lymph; with a lancet armed with the matter, punctures were made at short intervals all round the circumference of the tumour, and several points in the centre of it. To ensure its taking, I inserted into each puncture a bone-point, also well armed with vaccine lymph; most of these punctures took, and the irritation they caused was considerable, the child's face and head being swollen enormously. This was attended with fever and much constitutional disturbance, but at the end of a fortnight it had somewhat abated, and at the end of a month the disease was evidently decreasing; and at the expiration of six months from the vaccine lymph having been used, not the least swelling existed, and the skin was assuming its natural colour. I saw the child the beginning of January (1852), and not a vestige of the morbid structure remains, and it was only by looking closely for the vaccination scars, that I could tell on which side the nævus had been. I have treated several cases in the same way at the Kent Ophthalmic Hospital, and have succeeded in arresting their growth, but I have never seen so large an erectile tumour cured by this treatment, nor can I remember to have read of any such case. The colour of this vascular tumour was venous, the bleeding was arterial.—*Lancet.*

SYNCOPE.

By Mr. B. W. Richardson.

Syncope may arise from two kinds of derangements in the circulating machinery—1st, from blood being *diverted* from the heart; 2nd, from the heart being *overcharged* with blood.

The heart does not depend for its power to act on any nervous agency, but simply on the stimulus of blood. The value of the recumbent posture in restoring animation during syncope, does not rest on the cause (so commonly believed) that during recumbency the brain is resupplied with blood, and so the heart with nervous power, but on the fact, that when a person faints while sitting or standing, the heart fails to do more than to throw its blood over the arch of the aorta; and as this even is not done with sufficient force to ensure a returning venous current in opposition to gravity, the whole of the blood is allowed to accumulate in the vessels below the heart. But the patient at this point falls, or is laid down, with the upper part of the body lowest, the position of the ascending venous currents is thus entirely changed, the returning blood gravitates into the heart, and the organ, resupplied with stimulus, starts again into play, and animation returns.

This explanation affords also a key to many pathological phenomena; thus hæmorrhages from the lower half of the body are always much more dangerous than those from the upper, because in such cases the lower half of the body is a running cistern, not a reservoir of blood.

Syncope, following purgation, or the abstraction of fluids from cavities, is induced by the sudden rush of blood that takes place into the unloaded parts, the heart being thus as effectually robbed as in hæmorrhage.

Ruptures or wounds of the heart may not be followed by instant death, and this especially holds good if the wound or rupture occurs at the upper part of the organ; because in such cases, as soon as the organ gets so full as to pour out its blood through the artificial opening, contraction of the walls of the heart begins to take place, which contraction, as it expels the blood through the natural channels, closes also the rupture or wound.

Rupture of the sound heart scarcely ever occurs, except from a severe fall, in which the body alights on the feet or breech. Such falls lead to rupture of the heart or aorta, by the concussion of falling bringing down the blood that is passing through the ascending aorta, in the same way as the concussion produced by bringing the bottom of a bottle, containing a fluid or powdered substance, sharply on a hard body causes the powder or fluid to sink lower. In this way, also, aneurism at the root of the aorta is accounted for, as produced by leaping, riding, and the like; here the concussion, though not sufficient to cause a rupture, leads to a state next to rupture—viz., dilatation.

A beautiful provision against these accidents is found in inferior animals, where running, leaping, &c., are required, inasmuch as in them the circulating currents from the limbs do not enter the heart perpendicularly, but through the medium of horizontal vessels, so that no amount of concussion in falling upon the feet can overwhelm the heart with an increased flow of blood upon it.

In syncope during advanced pregnancy, the danger is very great, because the recumbent position is of no avail; for the gravid uterus falling backwards on the vessels running to the heart, acts like a ligature around them.

Syncope in labour never, or at all events rarely, occurs during a pain; this, in consequence of the mechanical necessity, that by each uterine contraction a large quantity of blood previously contained in the uterus is poured back into the general circulation, by which the heart is continually supplied with stimulus.

Heat, applied to the general surface, will sometimes give rise to syncope when the heart is hypertrophied. The syncopal attack is brought on in this case from an increased temperature dilating the capillaries, into which the over-acting heart forces its blood and empties itself.

Syncope may occur from the heart being overpowered with blood, and becoming paralyzed by its own efforts, in the same manner as ordinary muscles are sometimes temporarily paralyzed by sudden extreme exertion. Death probably arose from syncope so induced in those experiments on rabbits where Sir Astley Cooper suddenly arrested the flow of blood passing through the carotid and vertebral arteries; and cases are narrated in which a tendency to syncope has followed the compression of large arteries in the human subject.

The heart may also be overwhelmed from causes acting on the venous system. Thus from the days of Harvey it has been known that, in abstracting blood from the arm, the patient often faints on the removal of the fillet. This ensues from the flood of venous blood suddenly released, returning upon the enfeebled heart and overpowering it in a greater or lesser degree, just as in transfusion of blood after hæmorrhage the heart is liable to be overpowered if the injected blood is thrown into the circulation with too much force. A case is also supplied to illustrate a temporary mechanical arrest of the venous circulation in the neck may be followed by the same effects on the obstacle being suddenly removed.

Under the head of syncope from derangements of the heart, the effects of barriers (as indurated valves, &c.) in the cavities of the heart, and the effects of shocks to the heart, are considered. Reasons are adduced to prove that barriers on the left side of the heart are most dangerous, and it is suggested that all barriers act detrimentally in two ways—1st, by opposing the currents of the blood; 2nd, by preventing the walls of the heart from approximating closely during their contraction, thus rendering the organ unfit to adapt itself to various quantities of blood.

Among the causes which act on an *obstructed* heart to produce syncope, *exertion* is placed first by Mr. Richardson; and the doctrines of Dr. Latham concerning shocks to the heart are dwelt upon. It is shown that the cause why the heart never gets over a severe shock, as described by Dr. Latham, rests in the fact that the heart can never rest after the shock, and so never regains full power. It may play on, but its nice equilibrium is lost.

Exhaustion of the body, and sudden changes of position, are also common causes of syncope during the existence of obstructions at the heart. And lastly, in some states the blood during life, in the course of agitation against the valves of the heart, may deposit its fibrine; and in the event of an indurated valve being present, a fibrinous coagulum may be suddenly deposited upon it, of sufficient size to arrest the play of the heart, and to bring on fatal syncope.—*London Jour. of Med.*

REVIEWS AND NOTICES OF BOOKS.

LATERAL CURVATURE OF THE SPINE; its Causes, Nature, and Treatment. By R. W. Tamplin, F.R.C.S.E., Surgeon to and Lecturer on Deformities at the Royal Orthopædic Hospital, &c. &c. London. 1852. 8vo. pp. 44.

The substance of this treatise, the author informs us in the preface to it, has already appeared in his "Lectures on the Nature and Treatment of Deformities." He has been induced by the advice of many professional friends to publish in a separate form his views respecting lateral curvature and its treatment.

The circumstances under which lateral curvature of the spine arises are briefly laid down by Mr. Tamplin as follows:

"1. From any cause by which the movements of the lower extremities are rendered irregular; in other words, when the uniformity of their action is destroyed.

2. From general debility, or simple loss of the healthy tone of the system; from general debility consequent upon, or combined with, true rachitis, with its attendant and unhealthy state of constitution.

3. From any occupation by which the muscles of one side, or of one extremity, are more frequently exercised than those upon the opposite side."

This deformity originates, as Mr. Tamplin correctly observes, independent of any disease of the bones, ligaments, or muscles, the rachitic condition alone excepted. Its immediate cause, "in all cases, is purely mechanical—namely, the superincumbent weight of the head and upper extremities, combined with an instinctive effort, always in operation, to retain the head in the perpendicular position with the sacrum, with inability of the muscles and ligaments to accomplish this object when once a permanent curvature has taken place."

The following is the author's account of the ordinary progress of the symptoms in a case of lateral curvature of the spine:—

"Lateral curvature, when unaccompanied by rickets, generally commences about the age of 10 or 12 years. The first object which attracts attention is a fulness or projection of the shoulder—the shoulder corresponding with the convexity of the curve; also, a supposed enlargement of the hip, generally in the opposite side to the upper curve. Upon placing the patient in the horizontal position, an undue amount of lateral motion in the spinal column is generally observable. The curvature is perceived only when the patient is in the erect or sitting posture; and when in the horizontal, very slight pressure will not only straighten the spine, but carry it beyond the straight line, producing temporary curvature in the opposite direction. As the head cannot be retained in the perpendicular position with the sacrum, and we have only one portion of the spine curved, a second curve takes place lower down, in the lower dorsal and lumbar vertebræ.

As the deviation proceeds, the ribs, from their direct attachment to the vertebræ, suffer also from displacement, and project upon the convexity of the spinal curve, falling in upon the concavity. Hence the fulness or projection of one shoulder, and the depression or the flattening of the other. The sides of the chest and abdomen alter in shape, according to the nature of the deformity; being hollow on the concavity of the curve, round and projecting on the convexity. The ribs become compressed, and approximate to one another, also to the ilium on the one side—raised from the ilium, and separated from one another, more or less, upon the opposite side, which gives one of the hips an appearance of increased size. For this alone patients often apply for relief, and are more alarmed at the supposed enlargement of the hip than at the curvature. The height of the shoulders is unequal; the one appears raised, the other depressed, and more or less approximated to the hip of that side. The chest, also, partakes of the alteration of form, being flattened and depressed on the side corresponding with the convexity, full and projecting on that of the concavity. The bodies of the vertebræ, likewise, of necessity deviate from their normal position, being more or less separated from each other in the convexity of the curve; approximated and in close apposition on the concavity. The intervertebral substance, from the continued and undue pressure to which it is subjected on the concavity of the curve, becomes at first compressed, and eventually, in the most severe cases of many years' standing, absorbed; whilst the ligaments are elongated on the convex side, and contracted on the concave side, offering the most obstinate resistance. The muscles on the convex side are rendered more prominent, less so on the concave side, from the alteration of their position by the spinal deviation in connexion with the deviation of the ribs."

This deformity, the author thinks, may be traced in many instances to the general debility and loss of tone produced by the system of discipline pursued in many of the boarding schools for girls; and he quotes, in proof, the following account of the routine of one of these establishments, for the accuracy of which he is enabled to vouch, which appears to be very well calculated to bring about such a result:—

"At six o'clock in the morning the girls rise; from six to eight learning or saying lessons in school; eight to half-past eight, breakfast; half-past eight to nine, preparing lessons out of school, some of the girls being permitted to do so in the garden; nine to one, at various tasks in school; one to half-past one—out of school, but must not go out of doors—reading or working, and preparing for dinner; half-past one to two, at dinner; two to five in school, various tasks; five to half-past five, tea; half-past five to six, preparing to go out, dressing, or reading, or playing in school; six to seven, walking, generally arm in arm, in the high road, many with their books in their hands, and reading. It is to be remarked that they never go out unless the weather is quite fine at the particular hours allotted for walking. . . . . The twenty-four hours are therefore thus disposed of:—In bed 9; in school at their studies and tasks 9; in school or in the house 3½; at meals 1½; exercise in the open air 1."

That the practical results of such a system are not overdrawn is evidenced, the author observes, by the following fact—"We lately visited, in a large town, a boarding school containing forty girls, and we learnt on close and accurate inquiry, that there was not one of the girls who had been at the school (and the majority had been as long) that was not more or less crooked. Our patient was in this predicament, and we could perceive that all her companions were pallid, sallow, and listless." "We can assert, on the same authority of personal observation, and on an extensive scale, that scarcely a single girl (more especially of the middle classes) that has been at a boarding school for two or three years, returns home with unimpaired health."

"Happily, a portion of the ill-health produced at school is in many cases only temporary, and vanishes after the return from it. In the schools in which the vacations are frequent or long, much mischief is often warded off by the periodical return to the ordinary habits of healthful life; and some happy constitutions unquestionably bid defiance to all the systematic efforts to undermine them."

The plan of treatment pursued by the author consists in supporting the spine in such a manner that, while the deformity is being cured, relieved, or any increase prevented, the patients may be enabled to follow their usual avocations, and to take such general exercise as is conducive to, and absolutely necessary for, the preservation of health. For this purpose, the author employs instruments "which possess the power of adaptation to any form of curvature, with the pres-

sure so applied that no part is interfered with beyond the pelvis and the projection, where it is required; having a crutch on the concavity of the curve attached directly to the band, which assists in taking off the weight of the body, and preserving the balance of the instrument." "In cases of curvature of long standing, it requires to be worn night and day, so that no return to the malposition can take place; for if the just position be not constantly maintained, the ligaments cannot recontract, neither can the resistance offered by them on the concavity of the curve be so effectually overcome."

The author illustrates his description with figures of lateral curvature of the spine in its different degrees, and of the several instruments invented and employed by him for its relief. The latter appear to be extremely well adapted to the purpose intended, and they seem to be capable of fulfilling all the indications which can be expected from mechanical apparatus in affections of this nature.

DUBLIN: WEDNESDAY, MARCH 24, 1852.

POOR-LAW MEDICAL RELIEF.

THERE is, we hope, no "*finality*" in Poor-law Legislation, no more than in Reform Legislation; otherwise we should be in a state of utter despair as regards the prospects of our brethren of the Dispensaries under the new arrangements. It is evident that the whole scheme or system of medical relief in both countries (if it can be called a system) is the result of crude conceptions and feeble efforts, having no sound principle in view, and based on no solid foundation. A temporizing policy evidently sways the decisions of the governing bodies in this department; and that it should do so in Ireland at the moment when an experiment is in progress, does not surprise us; but that after so many years of experience it should still prevail in England, we cannot understand. We throw this out by way of a crumb of comfort to the suffering victims of the change which has just taken place in this country, and cold comfort it is; but we throw it out to remind them that every nerve must be strained to compel those entrusted with the execution of the Dispensary Act to discharge that duty with honesty and humanity on the one part, and with boldness and resolution on the other. We have said that no sound principle appears to guide in this matter, but there is evidently an unsound one, or something worse than an unsound one, the principle of substituting shadow for substance. It is impossible to contemplate the present state of this department, after a perusal of its official history since its origin, without coming to the conclusion that a fixed conviction prevails, which leads to a reluctant compliance with the letter of the law, rather than to a hearty adoption of its spirit; a display of unwilling obedience to a hard necessity rather than an anxious wish to discharge an agreeable duty. We really begin to think that the Poor-law authorities entertain some undefined notion that the medical relief of the poor is something of the nature of a sham, a result of a popular delusion which must be provided for, but not a positive object to be resolutely achieved. How else are we to account for such a state of affairs as this paragraph reveals, what better proof can be adduced that the settlement of the matter is voted a bore at head quarters, and that doctors and guardians are left to fight it out as best they can:—

The guardians of the Wolverhampton union are now engaged fixing the scale of remuneration to medical officers at so much per case for each pauper. The sums proposed are 2*s*., 2*s*. 6*d*., 3*s*., 3*s*. 6*d*., and 5*s*. 6*d*., per case. They are also discussing whether medical officers shall be appointed to each district, or whether the poor shall be allowed to employ any medical gentleman they shall please. The relieving officers are opposed to giving such an option to the poor, as in that case the doctors would oftener give an order for food than they would prescribe medicine. They also assert that they could produce a hogshead of medicine which the doctors prescribed, but the poor never used. In fact, they say, that almost all the applications are "bread-and-cheese cases," and that while they (the relieving officers) only gave 578 orders, the medical men had 1985 patients. The present remuneration paid the medical officers averages 1*s*. 4½*d*. per case.

But what concerns us is the apprehension that this "fight dog, fight bear" policy should be adopted in Ireland, and that our Dispensary Surgeons should be left to their own resources for defence against half-famished ratepayers. After a protracted struggle, repeated remonstrance, and unequivocal expression of doubt as to the necessity for the measure, an act is passed to overturn existing arrangements for the medical relief of the poor, on the ground of their insufficiency, and to substitute others for them. No sooner, however, is this fact accomplished than we perceive something very like a hesitation as to its execution. The principle of the measure thus asserted by parliament, and acquiesced in by the poor-law authorities, is it seems to be practically questioned in each of the 163 unions of Ireland. It is not the Commissioners, it appears, who are to enforce the law, but the parties interested in its evasion. The act says, medical relief shall be provided for the poor, the Ratepaying Guardians concur, and the Commissioners assent, but what is the practical result? As far as we have been able to ascertain, in many instances the result is but a compromise, a mere cheating of the foul fiend in the dark; for appointing a surgeon to scour the side of a country daily, in pursuit of the sick at distances of five, ten, or fifteen miles, upon a salary of £60 a year, is little else; in fact, the thing is impossible, and those who are parties to it well know that it is so. But lest all this should prove insufficient to secure for the state full value for the expenditure, an additional duty is imposed by which the "medical officer" is made the officer of another department not yet fully developed in this country. He is to collect the materials for annual returns touching sanitary statistics, for the glorification of some Registrar-General in embryo; and all "into the bargain." We conclude the big books in which the Doctors are to place on record their labours in this way have reached them, and that they have discovered the pleasant amusement provided for the evenings of their days of toil; but in the meantime we venture to protest on their behalf against the imposition of this extra duty without specific remuneration. We deny altogether the right to demand any such sacrifice of time without a proper consideration. The Surgeon is paid for attendance on the sick poor, and not for drawing up medical statistics. The printer of these books, "we guess," will be paid for them, and handsomely too; he who fills in the blanks must be paid also. Nothing for nothing is the order of the day, and no penny no *pater noster* has now become a rule of medical practice. The following is an extract from a letter before us on the subject:—

. . . . . No less than seven magnum books put into my hands, as if I was a clerk from the cradle to the grave; but to give my time up to this department is quite out of the question. The secretary is tired already, although but his second attendance; and so is the chairman, and every man on the committee. . . . . .

MIDWIVES FOR THE POOR.

The following suggestion is entitled to consideration, although some may perhaps entertain doubts as to the possibility of the proposed measure, or perhaps as to the prudence of its adoption under the present unsettled state of medical affairs. Practitioners conversant with the deplorable state of destitution in this respect prevailing in rural districts in Ireland will, however, readily concur in the humane views entertained by Dr. Mackesy, and will doubtless second his efforts, should a prospect of success present itself:—

WATERFORD UNION.

At the usual weekly meeting of the board on Thursday last, the following proceedings took place relative to dispensary districts:—

Dr. Mackesy said—I am anxious to place on the proceedings of this board a resolution I hold in my hand, to elicit the opinion of the Poor-law Medical Commission on the eligibility of appointing well-conducted educated nurses to the dispensary districts. This is a point of great consequence, not only in the preservation of the lives and health of the poorer classes, but also to the farmers and those residing in the country, whose circumstances do not enable them, in ordinary cases, to employ regular professional attendance; and should I succeed in establishing a better class of nurses in the country, sufficiently educated to judge of the necessity of having surgical advice *in proper time*, and capable by their attention and sobriety of discharging their duties, it would, in all probability, be the first great advantage the farmers have experienced from the poor-law; for I should expect that they would gladly avail themselves of the services of such qualified nurses for their wives when they were not engaged in dispensary duties. This is no new subject, for the grand jury had for years the power of presenting £20 or £30 at each assizes for the education of a nurse at the Rotundo Lying-in Hospital, Dublin, so that it is only removing this power from the grand juries to the poor-law; and in general the nurses sent up by the grand juries, when educated, did not remain in the districts which had paid by taxation for their education, but settled in some city, and acted as monthly nurses—thus the poor derived no benefit from the taxation imposed on them for this purpose; but the salary I propose should be allowed, will not only induce numbers of well-conducted women to attend the hospital for midwifery education, but will secure the future residence of the dispensary nurse in the district. This is a subject difficult to enter on at a meeting like this, but I hope that my inability to do it justice will not deprive me of the support of the members I see around me in carrying out the arrangement, as I am satisfied, from my professional practice, of the great advantages that will result from it. Dr. Mackesy concluded by moving the following resolution, which was seconded by Alderman Woods, and passed unanimously:—

"That the opinion of the Commissioners be solicited as to the advantage of appointing to the dispensary districts nurses of good character, regularly educated by attendance and lectures in lying-in hospitals, to act as midwives in ordinary cases, under the direction of the dispensary surgeons; and that should the Commissioners approve of such appointments, that they be requested to issue instructions for the qualifications that should be required, and for the arrangement of the duties of such nurses."

BOOK-ADVERTISEMENTS OF THE QUACKS.

It is odd enough that this most obvious insult to the medical profession should now be first exposed, and by "A Young Hospital Student," although it has been in operation for several years. But it is not in this respect only that the character of the medical profession is sacrificed, and medical science obstructed in its progress to serve the purposes of trade. The day may perhaps one day arrive when Physicians and Surgeons will take steps to cure this evil:—

HOMŒOPATHIC AND MESMERIC PUBLISHERS.

Sir,—I have just received from M. Baillière of Regent-street, a pamphlet containing a list of works published by him. A large portion of them are upon homœopathy and mesmerism. As he is probably thus insulting the profession generally, would it not be as well for those members who have received the paper in question to follow my example, and return the paper to him, with an intimation that they will not purchase books published by him as long as he places them side by side with humbug and imposture.—Believe me, yours, &c.,

—*Lancet.* A Young Hospital Surgeon.

To Correspodents.—We are fully aware of the disgraceful and dishonourable proceedings adopted to prevent the accomplishment of contemplated improvements in medical education, but what can we do? To tell our readers that the party alluded to has uttered the falsehood stated, would not mend the matter; neither would it avail to expose the turpitude of the course pursued by the others, as long as our profession tacitly acquiesces.

PAYMENT OF HOSPITAL SURGEONS.

Our correspondent "Spes," whose letter appeared last week, really has good grounds for hope in the cause to which he addresses himself. We were not aware that so many of the metropolitan charities gave an annual grant to their medical officers. But there is, on this account, the greater reason why the other hospitals and dispensaries should follow the good example. Let us have more information on this subject. The question is one which could only be decided in favour of the medical officers when once fairly discussed by the hospital authorities. While an annual sum is given to the physicians and surgeon's at Guy's, St. Bartholomew's, and St. Thomas's, why should the medical officers of St. George's and the London Hospital be expected to give their time and services gratuitously? We can understand why there should be no medical remuneration at some of the younger charities, or when the expenditure barely equals, or falls below, the income; but in hospitals with splendid revenues like those we have named, its absence shows a great selfishness and want of consideration on the part of the governors. Besides the actual remuneration in money, it would be well to ascertain the financial relationships between the various schools and the hospitals around which they have grown up. We believe the most different regulations exist in this respect at the different hospitals. Thus, we are told that at University College Hospital, the whole of the fees for hospital practice are absorbed by the hospital; while at King's College Hospital, they are divided among the medical staff. The publication of such inequalities must tend to their adjustment upon some proper plan. Another important branch of the subject relates to the hospitals and infirmaries of the provinces. Information on this subject would be most valuable. It has often been said that hospital appointments pay their possessors indirectly, by leading to practice. But this cannot be averred with the same truth as formerly, when hospitals have increased in number, and now that the medical staff of each hospital is so much more numerous than formerly. In our times hospital appointments are looked upon rather as giving opportunities for work and laborious investigation, than as direct introductions to practice. Much more than the name of being hospital physician or hospital surgeon is required to ensure the most moderate success in practice. There is another point in the modern regulations of hospitals which requires consideration. There is now, at all our public institutions, a numerous staff of assistant physicians and surgeons, who have little chance of early success in practice. The old hospital work was a holiday matter compared with the present. There are in London many assistant physicians and surgeons who have grown grey in their probationary state. Ten or twenty years—the very heart of a man's life—may pass away even after he has entered the hospital precincts, and is fairly on the groove, before he has full opportunities of showing the stuff he may be made of. There are actually men who have reached the council table of the College of Surgeons, still hospital assistant-surgeons—old men in years, but mere juniors in hospital rank. We did not start this subject without due reflection, and we trust some tangible good may follow upon its discussion.—*Lancet.*

MEDICAL BLOOMERISM.

Everybody who reads *Punch* and the newspapers has learned that some crazy transatlantic women have been vainly endeavouring to induce the British fair to assume half the dress and many of the most arduous duties of the other sex. A little modification of the petticoat and the corset is, I grant, very much needed; but a rational reformation in female dress can never be brought about by such apostles as are now, or have lately been, preaching the doctrines of the Bloomer crusade. Much less can such individuals do aught for the other cause which they pretend to espouse, "the rights of women." It is true that in the eye of God, as revealed to us in his word, "the rights," and the eternal destiny of both sexes, are the same; but it is as clearly told to us in the Bible, as it is emphatically declared by the physical structure of our race, that, when in this world, the man and the woman has each a distinct mission—that the one is a help meet and suitable for the other, and that the proper discharge of the duties of life require each to perform separate parts. The larger bones, the stronger muscles, the sterner mind, and the ruder aspect were, not without a wise design, conferred on one sex and withheld from the other, whose very charms and powers of doing good depend in no small degree upon the manner and proportion in which are impressed characteristics the opposite of those enumerated. Were our wives and our daughters to desert their nurseries, their domestic parlours, and their drawing-rooms, for military colleges, inns of law, dissecting-rooms and halls of science, the professions of arms, of law, and of medicine might derive some talented recruits; but every woman so withdrawn from the household sphere would create a disastrous void at home; and if it were possible (which, thank God, it is not) for such an insane fashion extensively to prevail, our children would grow up degenerate and untamed—a generation selfish, devilish, and savage. So it ever has been when want, ambition, or love of lucre has induced mothers to surrender their humanizing dominion at home. Abundant examples might be drawn from our cotton-spinning towns and our mining districts—as well from the tabernacles of the poor, as from the gorgeous saloons of London or Parisian folly. If there be truth in these remarks, it cannot be too deeply regretted that some distinguished members of the medical profession bestowed marked attention upon that famous American lady, Elizabeth Blackwell, M.D., during her recent visit to the hospitals and medical museums of London and Paris. It might be a curious, but it was an odious spectacle, to see that unwomanly lady attending operations at our hospitals, and exploring cabinets of pathology with scientific gusto. The evil of her reception is now being felt, for this Dr. Elizabeth Blackwell, graduate in medicine of an American University,* has returned to her native country, and is now exulting through the press at the kindness which she met with from this and the other medical professor of London and of Paris. I know not the length of Dr. Blackwell's petticoats, but her political and social creed is of the ultra-Bloomer or Social school. In a report of the proceedings which took place at a "Convention of Women," recently held on the other side of the Atlantic, I find it stated that Lucretia Mott of Philadelphia, and Elizabeth Blackwell, M.D., of New York, were appointed as "a committee to correspond with Jeane Deroin and Pauline Roland of Paris, and to express to them the interest of this Convention in the present position of France." The French women named are, or lately were, prisoners in the St. Lazare of Paris, for political offences. Jeane Deroin was editor of a Socialist paper called *The Voice of Woman*. Such are the characters with whom the lady-doctor lately wondered at in London is identified. In the New York newspapers it is advertised that "Elizabeth Blackwell, M.D., has returned from Europe and *opened an office* in New York," which means that she has commenced consulting practice as a physician in that city. From the *Philadelphia Medical Examiner* it appears that the indelicacy of young men and young women attending together the same classes and dissecting-rooms is complained of, and that, as it is supposed that the female sex are likely ere long to enlist themselves in large numbers under the banners of Esculapius, a medical school specially for women is now being established in Philadelphia. Is not civilization in its dotage?—*Celsus in Critic.*

* Graduation in America is on a strange footing. The degree of M.D. can, in some schools, be obtained by all sorts of quacks, as well as by ladies.

STRICTURE OF THE URETHRA.

George Humpage, aged 40, affected with stricture of the urethra, admitted in the Queen's Hospital, October 25, under the care of Mr. Parker. On examination, his bladder was found greatly distended; he complained of much pain, and a constant desire to pass water, which he could only do by drops. The urine was clear and did not deposit. He could not sleep at night and his countenance was haggard, and showed signs of acute and long-continued suffering. His bowels were moved daily, but his appetite was gone. It appeared that he had experienced much difficulty in passing his water during the last two years; that he had neglected it, and in consequence had become gradually unable to make the slightest stream. He had frequently suffered from gonorrhœa. On a bougie being introduced, the whole of the urethra was found to be in a hardened, semi cartilaginous state, and the smallest instrument could not be passed more than three inches and a half. As the patient complained very bitterly, it became a question what treatment should be adopted; but a sufficient quantity of urine passing during the twenty-four hours, Mr. Parker ordered a bougie to be introduced daily, and suffered to remain a short time, while the patient took five grains of soap and opium pill at bedtime. This treatment was continued until November 15, an occasional dose of castor oil being required to regulate the bowels. The bougie would pass about four inches, but was then stopped by an impediment harder than anything which had been overcome. A small silver catheter was now used, and in two or three days it could be readily passed as far as the membranous portion. He was now put in a warm bath daily, and on two or three occasions had leeches applied to the perineum, the catheter being used after each bath. On November 26, a No. 6 catheter was passed fairly into the bladder, and a considerable quantity of urine taken away. The instrument was allowed to remain for an hour. On November 30 it was again introduced, secured by tapes, and kept in the bladder about thirty-six hours, during which time suppuration was established; and on its removal the patient in a few days could make water with great facility, and in almost as good a stream as he ever could. On his discharge he was free from pain, much increased in weight, and his countenance showed none of the haggard appearance it did on admission; a No. 8 catheter could also be passed with perfect ease. He was advised to have a bougie passed at intervals for some time.—*Prov. Jour.*

M. W. HANLON, M.B.

Amputations in Children.—M. Guersant has repeated occasions to amputate the limbs of young children in the Hôpital des Enfants Malades. He generally adopts the flap operation, and seldom or never performs the circular. Chloroform is always used. He is very careful in preparing the patient for operation, and allows a liberal diet after it, which latter is the secret of his great success.

TO ALEXANDER KNOX, M.D.,

INSPECTOR OF MEDICAL CHARITIES.

The Medical Superintendents of the Dispensaries and Fever Hospitals in Ireland, have learned with regret that they have been deprived of your valuable services as Honorary Secretary to their Association, and they cannot allow your connexion with them to cease without recording the high opinion they entertain of your character and ability, and offering you their best thanks for your unremitting and laborious exertions to improve the condition of the Medical Charities of this country, as well as to uphold the interests and advance the respectability of the medical profession.

It was their wish to have added to this expression of opinion some more substantial proof of their esteem, but as you have declined receiving any testimonial of pecuniary value, they can only assure you that, in selecting you to fill the important office of Inspector of Medical Charities, the Poor-law Commissioners have given universal satisfaction to the medical officers of those institutions.

Signed on behalf of the Medical Superintendents of Dispensaries and Fever Hospitals in Ireland,

W. Kingsley, M.D., Chairman.
J. Morrison, M.D., Treasurer.
J. Waters, M.D., Hon. Secretary.

February 21, 1852.

DR. KNOX'S REPLY.

Gentlemen,—I beg you will do me the favour to convey to the Medical Superintendents of the Irish Dispensaries and Fever Hospitals my sincere thanks for their very kind Address, presented to me on the close of our official connexion, with reference to the change in my position, to which they allude in terms so gratifying to my feelings.

At the same time, I am happy to have the opportunity of assuring them of the grateful recollection which I retain of their generous support and confidence throughout the entire period in which our exertions were directed to the improvement of the laws affecting the Medical Charities of this kingdom, on principles which we considered to be favourable alike to the true interests of the poor, the medical profession, and the community at large.

I have still further to convey my obligation for the kind feeling which prompted the desire to add to the very gratifying expression of the opinion of my professional brethren some more substantial proof of their esteem, and I feel satisfied that I do not err in the expectation that they will properly appreciate the motives which influenced me in respectfully declining the offer of any testimonial of pecuniary value as soon as the proposal was brought formally before me. Such services as it was in my power to render, were willingly bestowed, and at any rate I prefer to any pecuniary recompense, the cordial and spontaneous approval of my conduct conveyed in the language of the Address, and which I shall always regard with satisfaction, as the best reward for any efforts in my power to make, to uphold the respectability of the noble profession, in which for more than a quarter of a century I have been a fellow-labourer.

I shall only add that, under any circumstances, I trust I shall always, as now, be animated with the most anxious desire to maintain the real interests of the medical profession, as I look on them, if properly understood, as inseparable from the interests of every other class in the community.

Believe me to remain, Gentlemen,
With the utmost esteem and regard,
Your obliged and faithful servant,
Alexander Knox, M.D.

To Drs. Kingsley, Morrison, and Waters,
&c. &c.

THE MEDICAL DIRECTORY FOR IRELAND, 1852,

Price 6s., is now ready, containing the Name, Address, Qualifications, Appointments, and Literary Productions of every known qualified Practitioner in that Kingdom—Almanac—Universities—Colleges—Halls—Hospitals—Dispensaries—Medical and Scientific Societies—Obituary,—and a large amount of Miscellaneous Information relating to the Medical Profession.

London: John Churchill, Princes-street, Soho; and 4, Adam-street, Adelphi. Dublin: John Fannin and Co, 41, Grafton-street.

UNIVERSITY OF LONDON.

Notice is hereby given, that on Wednesday, 21st of April next, the Senate will proceed to elect Examiners in the following departments:—

Examinerships.

The present Examiners are eligible, and intend to offer themselves, for reëlection.

Candidates must announce their names to the Registrar on or before the 13th of April.

By order of the Senate,
R. W. ROTHMAN, Registrar.

Somerset House, March 16, 1852.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT
is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention*; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

Bleeding, Cupping, the Application of Leeches, &c.

G. O. and Co. continue to be Supplied with the Foreign Mineral Waters Fresh from their various Springs.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

SURGICAL SOCIETY OF IRELAND.—MARCH 6.

Mr. TRANT, President of the College, in the chair.

ON THE CANCEROUS DEGENERATION OF WARTY EXCRESCENCES, AND THEIR TREATMENT.

By RICHARD G. H. BUTCHER, F.R.C.S.I.,
Examiner on Anatomy and Physiology in the Royal College of Surgeons in Ireland, Surgeon to Mercer's Hospital, &c. &c. &c.

MR. PRESIDENT,—On a former occasion I had the honour of bringing before the notice of this Society a paper on the relationship that is found to subsist between cancer and fungus hæmatodes; and illustrated this alliance by preparations and specimens—1stly, when the diseases coexisted together; 2ndly, where the one was consecutive to, or replaced by, the other; and 3rdly, where the two manifestations of disease were continuous in the same tumour.

These facts are borne testimony to and established by the investigations of Langstaff (Med.-Chir. Trans., vol. ix.), Cruveilhier (Anat. Pathol., livr. xxiii., Explanation of Plates, 5 and 6), and others.

The observations which I now wish to lay before the profession are in reference to the cancerous degeneration of warty excrescences—an association which I do not think has met with all the careful attention from writers to which it is entitled. Entitled on two grounds—1st, from the frequency of the one as a sequence to the other; and 2ndly, from the inveteracy of the connexion when once established.

The following cases will afford exposition of the various changes brought about, from the apparently innocent verruca to the cancerous ulcer, and this again to the contamination of the system and the springing up of encephaloid disease. To illustrate still further this subject, I shall lay before the Society numerous casts and drawings, accurate representations of the respective changes as they were effected in each individual case, and shall conclude with a few practical deductions from the premises obtained.

Case 1.—Anne Sullivan, aged 52, applied to me for relief, in May, 1850, being then suffering severely from a large, painful, ulcerated tumour over the right eye. The history which she gave goes to prove that a wart about the size of a pea existed above the eyebrow ever since she was a child; that eleven months previous to her seeking my advice, it became painful and itchy; that she frequently tried to pick it away in little pieces, and often pulled long shreds out of it, the separation of which was always attended with sharp pain, lasting frequently for a lengthened period after, and usually with a smart flow of blood. About this time, too, the bulk of the swelling began rapidly to increase, with a red margin round it, and soon its appearance was altered in every respect from the original condition; the warty excrescence was cast off, and a small ulcerated surface, about the size of a shilling, lay exposed, which was elevated, hard, and circumscribed; yielding a thin yellowish discharge, and characterised by persistent pain of a pricking kind, subject at different times to various degrees of intensity. Day after day the tumour continued to enlarge, spreading its base by the accession of fresh nodules, which never rose to any greater height than half an inch above the surrounding healthy parts; the integuments thus appeared to ulcerate around, the destroyed part being supplanted with firm elevations, which, in their turn, coalesced, became convex, and in this way preserving the nodulated character of the entire surface. Thus the base extended widely in all directions—upwards on the forehead, inwards and beyond the mesial line, externally towards the temple, and down upon the cheek, and inferiorly so as to involve and depress the upper lid, and compromise vision in the right eye. The extent of ulcerated surface measured round its circumference ten inches. This amount of disease, then, was hurried into existence in the incredibly short period of eleven months. The character of the sore was peculiarly cancerous, the surface being nodulated, hard, and firm almost as cartilage, yielding a discharge thin, yellowish, and watery; profuse in quantity, and emitting the peculiar odour so pathognomonic, and readily recognized by the surgeon accustomed to meet with this form of disease. Eight months after the commencement of the disease in the forehead, a

tumour began to form in the upper part of the parotidean region; it gradually came on, at first attended with most severe darting pain through the ear, up along the side of the head, and forwards towards the face, and thus averting sleep for nights, even before there was any appreciable swelling. At this time, the pain, she states, to have been most agonizing; but it gradually declined as the bulk of the tumour was augmented. The size of this secondary growth obtains in magnitude about that of a split orange, and from its osseous boundaries its outline is not regular; it is also somewhat compressed transversely about its centre, and the upper part is more of an ovoid, while the lower portion is lobulated, and spread out. This cast, taken from the patient, most faithfully represents the appearances of the primary and secondary formations, and the colouration of each has been very carefully preserved. From a careful consideration of the phenomena attendant on this tumour, the rapidity of its growth, the character of the pain, the elastic sensation elicited by the touch, the colour of its surface, I concluded it was of encephaloid formation, and referred it to that class. With anxiety I watched this creature for some time, and in about five weeks after the cast was taken, the most prominent part gave way, and a fungus shot out, never attaining beyond the size of a large fig, and emitting from its centre, at intervals of a few days, repeated arterial hæmorrhages; some of them to the extent of several ounces. She struggled on in this way for two months, when she died from the debility consequent upon those frequent losses, and I regret to say I could not obtain any dissection of the body. I examined the structure of the original tumour several times with the aid of the microscope, and which most clearly proved its cancerous nature. A fine section of it showed the basis to be made up of fibrous tissue, having embedded, as it were, in its structure numerous nucleated cells; many with nucleoli. The addition of acetic acid had no other effect than that of rendering more conspicuous the nuclei at the expense of almost the dissolution of the cell-wall. On subjecting a piece of the tumour to pressure, a juice could be expressed from it yielding an abundance of cells similar to those visible in the section, and by the addition of acetic acid were acted on with a similar result. Numerous granular bodies were also floated through the fluid.

Here is a drawing of the microscopic appearances of the primary tumour, showing the arrangement of the fibrous tissue, cells, and granular bodies, which I have adverted to. The next point to be cleared up in this case was, carefully to ascertain the nature of the secondary formation, the tumour behind the jaw, and to trace out the affinity between it and the antecedent true scirrhus by microscopic examination. After the tumour had burst and the fungus shot out, I introduced a grooved needle into its structure about an inch deep, then rotated it between the finger and thumb, and on withdrawing it the groove was loaded with the morbid product. This was not uniformly of the same consistence; some parts were harder than others. On placing a small portion of it under the microscope, every atom absolutely teemed with a profusion of nucleated cells, supported with the most delicate filamentous tissue. On examining some particles firmer than others, the cells were much the same, the only difference being in the compression of the cells; while those of the softer portions approximated more closely to a sphere. There were no caudate corpuscles present in this specimen.

Here is a drawing of the appearance of the cells, as represented under the same power as that used in the first picture.

Case 2.—Jane Murphy, aged 70, a healthy-looking country woman, who had been mother of ten children, consulted me in January, 1849, for a small tumour situated beneath her chin in the mesial line. She mentioned that a wart had been there from childhood, but that within the last four months it had lost its form, the irregular surface becoming smooth, its size larger, and extremely painful. She had been in the habit of frequently pressing the tumour, endeavouring to allay the pain, which often induced it to bleed, and then the annoyance in a measure subsided. When I first saw this patient, the tumour was about the size of a marble, smooth and polished on the surface, with a semitransparency over it, of stony hardness and quite moveable. Taking these features into consideration, together with the characteristic pain, always of a lancinating nature, the altered aspect of the part, and the period of life at which it was brought about, I was led to the inference of malignant degeneration being set up in this change, and urged its immediate removal. Coexisting with this suspicious tubercle, there was a warty growth, larger than a pea, a little above the chin and to the left side. This, she said, also existed from infancy, never gave her any uneasiness, and exactly resembled the one beneath the chin, previous to the alteration above noticed. I removed the tumour beneath the chin in January, 1849, by two elliptical incisions, their long axis from above downwards cutting far wide of the diseased structure, and deeper by several lines than the bed of the tumour. The wound inflicted readily admitted of being brought together from side to side, and the edges retained so by two fine needles and the twisted suture, compresses were placed beneath the ends of each needle with a double object, to bear off any undue pressure and to act as on the principle of the quill suture in supporting the lips of the wound at their very deepest line in contact, and thus taking the strain off the needles. So effectual was the support and apposition afforded, that union by the first intention was constrained, almost through its entire track, the lower part only suppurating. In ten days after being cut, the wound was altogether healed, and the patient went to the country to her friends. Previous to her going home, I urged the removal of the wart above the chin, but to no effect; she would not submit to have it done. During nine months after the operation, she remained free from disease, and satisfied that a cure had been effected. About the end of this time, the wart, which had been permitted to remain, began to spread and get painful. The cicatrix resulting from the former operation became tender, tumid, and ultimately gave way by an ulcerated fissure, which rapidly grew wider, yielding a profuse ichorous discharge. The destructive action progressed for about a fortnight, when a fungous growth spread around the sulcus formed in the first instance, assuming the shape of a mushroom and the size of a crown-piece, its margin being turned over so as to rest upon the sound skin. She came up to town again for my advice, and I declined interfering by operation; the grounds of objection being chiefly founded on the presence of a deep sinus leading backwards towards the line of lymphatics, parallel and beneath the anterior margin of the sterno-mastoid muscle. Again, the root of the disease was struck so deep, and the width of the contaminating base so widely spread, that even the most expert operator could not be satisfied that the entire was removed. Palliatives were again ordered, and she returned to the country. For many months the disease very slowly increased, but the warty excrescence was very considerably augmented, its surface having ulcerated, and the same process spread its margin, until ultimately it joined the disease, spreading upwards from beneath the chin, the two having coalesced and become inseparably united together. During the last four months still further changes have been added; not only has the original manifestation of the disease been progressive, but we have formed two additional tumours, situated one on either side of the neck, and in the line of the absorbents, manifestly of encephaloid nature. Their springiness and elasticity, their colouration, and above all, the microscopic examination of their contents on exploration, pointed to, and confirmed the opinion of, their being true cephaloma. In this miserable state she endured, the gravity of the symptoms having been greatly increased, pain giving rise to the most intolerable suffering, the features being haggard and pinched, and the skin of a dull ochry colour, debility and emaciation having made rapid progress, and all the functions of the economy more and more becoming implicated in the deteriorating influence of the disease.

In this deplorable condition (in December, 1851), she went back to her family in the country, to await her final release from suffering, which, to all certainty, was not far distant.

Here is a cast accurately showing the condition of the parts previous to operation in January, 1849; and here is a second, graphically illustrating the changes which have been brought about, from the period of nine months after the operation, when the disease appeared in the cicatrix, with all the progressive changes up to the present time (January, 1851), an interval of fifteen months having elapsed. The painting of each has been most truthfully executed.

I have also preserved these microscopic drawings, taken of the primary and secondary tumours as they appeared. Here is one representing the appearances of the tumour that first showed itself beneath the chin. It exhibits a number of true cancer cells, scattered everywhere through a fibrous basis. Some separate cells are also seen detached.

This second drawing shows the arrangement of the encephaloid tumours which sprung up beneath the mastoid muscles. The structure seemed entirely composed of myriads of nucleated cancer-cells, and very closely resembled the secondary formation in the case of Sullivan; inasmuch as there were no caudate corpuscles in this specimen either, and the cells were held together by the finest areolar tissue.

Case 3.—Ellen Fitzpatrick, aged 65, consulted me in March, 1850, for a large bleeding wart, placed above and behind the right ear; it was attended for some time before with repeated hæmorrhages. She said it had been there for many years, never created any annoyance until about six weeks before seeking my advice. She referred the great change which had taken place in it to a bruise occasioned by a water pail that she had been in the habit of carrying on her shoulder. Shortly after this "the wart became very sore," and soon the pain set in, of intense character, darting up along the side of the head, down towards the angle of the jaw, and represented by the sufferer as "indescribably severe." On examining the part, a highly irritable and inflamed base surrounded the tumour, which was about the size of a shilling, uneven on its surface, and elevated about half an inch; it was hard to the touch, and bled upon the slightest pressure from an ulcerated line partly round it and through its structure.

I removed this tumour with great care, cutting far wide of the base, and as I thought most effectively. Two arteries sprung which required ligatures, and so free had been the excision that the edges of the wound would not permit of being brought together, yet it healed perfectly in three weeks by granulation, a soft yet polished cicatrix being left. For a period of eight months she continued quite well and exempt from all annoyance. After this time she began to complain of uneasiness behind the angle of the jaw on mastication: by degrees the part became tense, and then she felt a small tumour there. This at the time she believed originated from cold, and it did not alarm her, more particularly as she often relieved the urgent pain by repeated stuping. However, the swelling continued to increase so as to become perceptible, and when it attained such magnitude as to fill up the angle of the jaw, she began to suffer from the effects of paralysis of the facial division of the 7th nerve on the right side. Day after day the tumour extended itself, particularly in the direction of the site of the original warty excrescence. At this time she again sought my advice, and then the case was truly a lamentable one. A tumour, considerably larger than an orange, filled up the space between the angle of the jaw and the mastoid process, lost upwards towards the zygoma, passing downwards and encroaching on the neck, extending behind the ear, and implicating the structures attached to the occipital bone: uneven, projecting, and lobulated on its surface; fixed, irregular, and immoveable at its base. The colour of the tumour was very remarkable and strikingly indicative of the condition so frequently associated with the proper circulation of the true cephaloma. Large veins traversed it in every direction, some of them lying, as it were, in grooves embedded on its surface; while again numerous vessels marked the colouration in a peculiar way, constituting what might be called a number of vascular spots, from which capillaries radiated in every direction for a short distance, and ultimately breaking up into a fine ramiform distribution.

Here is a cast taken from the patient at this time, which most accurately shows the position, form, and colour of the secondary tumour, also the paralytic condition of the corresponding side of the face, from the implication of the motor portion of the 7th nerve with the morbid product.

The face is greatly distorted, and the right side very remarkable when contrasted with the other. Upon the forehead the integuments lie flat, smooth, and at rest, there being no wrinkles or motion as on the left side. A vertical furrow is placed nearly in the centre, dividing the bulging of the muscles on the left side from the uncontracted state of those on the right; and the slip of the occipito-frontalis muscle forms a remarkable prominence at the junction of the nasal bone with the frontal on the left side. The power of closing the eyelids of the right eye was lost; they remained always open. When asked to close the eye forcibly, although she made the attempt, there was not the slightest motion observed in the eyelids. When the eye was at rest, and the patient using the sound one, about half the pupil remained visible, but during sleep was completely concealed behind the upper lid. The conjunctiva of the eye was in a chronic state of inflammation, and exhibited through a lens a perfectly villous surface, permeated in every point with innumerable vessels. On close examination, the cornea looked dull, but at a little distance presented a borrowed brilliancy from the abundant flow of tears which were constantly secreted and pouring over the cheek. The lower eyelid drooped a little, and the mucous membrane lining it presented the same vascular arrangement as that covering the sclerotic coat. The right nostril lay flat, collapsed, and not distended on a deep inspiration, but rather closed altogether, and the nose pointed towards the left side. When she blew or attempted to whistle, the air escaped by the right angle of the mouth, the right buccinator not at all corresponding in action with the muscle of the left side, nor with that of the muscles of the chest and neck by which the air was expelled. In mastication, the food collected in the right cheek between it and the teeth, and the patient could not push it from its place without the assistance of the tongue, and frequently of the finger. The saliva constantly flowed out at this side, and when drinking part of the fluid likewise escaped.

When the disease attained the size represented in the cast, it did not at all increase so rapidly as at first; and during the following thirteen months I had repeated opportunities of watching the course of the disease, a part of it ulcerated, a fungus shot out, and attended by small hæmorrhages. I regret to say in January, 1852, this creature took typhus fever from an individual in the same lodging house, and died on the tenth day. I could not obtain permission for an examination of the parts.

It may be said, the cases of cancerous degeneration which I have brought forward all occurred in patients of advanced life. In most of the instances which have fallen to my lot for observation, it was so; but I have also seen the change brought about in early age, which the following cases will testify.

Case 4.—Maria Williams, aged 19, a particularly handsome girl, of dark complexion, consulted me in February, 1849, for what appeared a very irritable wart, and situated on the forepart of the neck. She mentioned it had been there as long as she could remember, but that latterly it had increased and become very painful, which she attributed to the pressure of her dress. The tumour when I saw her was the size of a filbert, hard and irregular on the surface, which at the highest point was elevated about a quarter of an inch above the surrounding healthy skin. It was quite moveable, placed about the centre of the depres-

sion situated above the sternum, and three-quarters of an inch from its upper margin.

The patient suffered great uneasiness in her mind from the rapidity of its increase, and the "dread of cancer," as her mother had died of that disease, and great depression and annoyance from the constant pain present in it.

Mr. Tagert, whom I consulted in the case, agreed with me that it was better to remove the part—a proposition to which the patient most readily acquiesced. I did so by two incisions, one on either side, and wide of its base, meeting above and below, and then by a few touches of the knife lifted the tumour in its perfect integrity from the subjacent cellular tissue. The lips of the wound were brought together with two fine needles and the twisted suture. Union by the first intention was nearly accomplished on the fourth day, and in less than a fortnight the part was healed altogether. During the three years which have elapsed, I have several times seen this young woman, and up to the present date there has been no return of the disease, either in the cicatrix or elsewhere.

I regret to say I have mislaid the microscopic drawing of the tumour cut out in this case, which I made most carefully; and more particularly so as bearing on a question about which I think a good deal of uncertainty still exists. From my notes, however, the following are the particulars. The specimen yielded epithelial scales, in various conditions and stages; some compressed together, forming laminæ, whilst deeper ones assumed a somewhat square form, some of them a caudate shape, whilst around the base there were other cells which I at once pronounced to be cancer-cells. When separated and broken up they did not at all seem disposed to run together, they were nucleated, some with nucleoli, and which, on the addition of acetic acid, were rendered more distinct, and the cell-wall was nearly dissolved, while the other cells resisted its action with impunity. I am quite sure I was not led astray here by an appearance that frequently takes place—namely, the enlargement of the epithelial cells from endosmosis.

Mr. Wardrop records a very remarkable instance of this cancerous degeneration of a wart occurring in a subject much younger than in the case which I have just related. "I had an opportunity (writes this eminent pathologist) of seeing an example of a true cancerous sore in a girl about 12 years of age, and it is the only case of the kind which has come to my knowledge. It appeared on the lower part of the abdomen, and begun in the form of a black wart on the skin. The wart ulcerated, and the surrounding skin was gradually destroyed, so as to form an immense ulcer, having all the characters of a true cancerous sore, which at last destroyed the child." *(Wardrop's Observations on Fungous Hæmatodes, p.* 189.)

Case 5.—The supervention of fungous hæmatodes, after the removal of a large wart from the inner side of the foot, is well exemplified by the following case which occurred in our hospital some time since:—Mary Murphy, aged 28, admitted into Mercer's Hospital, October, 1846, being the second time this year. In the preceding February she was received into the house for the removal of a large painful wart, fully the size of a half-crown piece, and situated on the inner side of the left foot. It occasioned her great pain, and was so irritable that even a stocking could not be worn over it, and it was deeply ulcerated round its base. At this time there was no evidence of internal disease, and the lymphatic glands of the extremities were neither indurated nor enlarged; therefore Mr. Tagert removed the part, and without difficulty, for it had no deep attachment whatever; it was quite loose, and readily floated on the surface from the slightest touch. The wound quickly healed, and in three weeks she returned to the country. Her second admission, as above dated, was nine months after this operation, when she was received with far advanced encephaloid disease in the groin of the same side. The history which she gave of the tumour in the groin is as follows: For five weeks after her return home—that is, two months from the period of the operation—she was free from all disease; that exactly at this time "a kernel" appeared in the left groin; it continued to increase for a month, and attained the size of a small apple, when it remained stationary for a short time. Up to this period there was very little uneasiness in the part. After this the tumour began again to enlarge, with a "bursting sensation" in it. During the following months her sufferings were greatly augmented, the tumour widely extending itself in all directions, irregular and nodulated on the surface, and highly sensitive. At this time, too, just before admission, the most prominent part burst, from which she lost a quantity of blood. In this state, then, she was received nine months after the operation, the tumour being larger than the clenched hand, accompanied by darting pains occasionally through it; but she refers an indescribable sensation of tension being always located in the upper half of it, and here, too, was a black spot marking the site from which the hæmorrhage had proceeded a few days before.

November 10th. Since her admission to hospital, the increase of the tumour has been most rapid; it is now enormous, measuring ten inches and a half transversely, and seven and a half from above downwards. Its colour is also greatly altered, being now of a dark purple and reddish hue all over. Its surface is irregularly lobulated, and deprived of skin, with the elevations coated over by a semi-opaque fluid, and the depressions containing unhealthy watery pus. The constitution is sympathizing acutely with this mass of local disease. The pulse is never under 120; she has at intervals during the night profuse perspirations; her countenance is haggard and of a yellowish hue; and all appetite is gone. One point in the upper part of the tumour is far darker than the rest, and from which point two ounces of venous blood trickled the evening before. There has been no return of the disease on the foot, but the cicatrix is very hard and firm.

13th. There was hæmorrhage last night to about two ounces, but it was readily restrained by a few dossils of lint steeped in spirits of turpentine and finger pressure.

18th. Had profuse hæmorrhage last night; she lost nearly a pint of dark blood; to-day she is greatly exhausted, and bathed in sweat; her pulse weak, yet throbbing, and 130 in the minute; the tumour is quite black and turgid from where the blood flowed last night, and all its lobulated and broken up surface seems a mass of sloughs; she does not complain of pain now.

19th. Is much depressed to-day; at six o'clock in the evening bleeding began again, at first slowly, and was staunched by pledgets of lint dipped in muriated tincture of iron. In two hours after it broke out afresh, and was perfectly uncontrollable. At this time the bleeding was frightful, it issued out in large bursts from the pultaceous disorganized mass. When pressure was made over one point, it welled up as rapidly from under another lobe of the fungus, and so on until death threatened by hæmorrhage; she was waxy pale, with violent jactitation of the arms, profuse cold sweat over the entire body, screaming for the windows to be opened and the admission of air. In these efforts at length all motions ceased, and though there was no appearance of life, yet the blood continued to flow for a few seconds longer, when the pulse forsook the heart, and then death.

On examination of the body, a tumour as large as a small melon, of the same nature as that in the groin, filled the iliac fossa of the same side, intimately attached to the fascia, and implicating the muscles in this region. The iliac artery and vein ran through its base, and below Poupart's ligament the femoral artery and vein were surrounded by the encephaloid structure situated there. This pathological condition may account for the fact of the total uselessness of pressure over either of the trunks in arresting the fatal hæmorrhage. On slitting up the artery and vein through their entire extent as they traversed this diseased mass, I could not by the closest examination find any solution of their integrity. Vessels of considerable size, both arteries and veins, however, could be discovered through the structure, with their opened up and patulous

extremities. These were very numerous, and evidently the source from which the blood issued in such quantities. The patulous condition of the arteries, as well as the veins, I ascribe to the matting of the coats of the vessels with the surrounding tissues, and thus neutralizing their contractile power. The softer parts of the tumour, on section, exactly resembled the brain in a state of decomposition.

Case 6.—The late Mr. Palmer of this city, had a case very analogous to the one just particularized, a short time before under his care, in Mercer's Hospital. The patient was a young woman only 24 years of age; she had a flat painful wart on the inner side of the knee; it was there for years, but having become very irritable and ulcerated, and bleeding from the least injury, she solicited for its removal; it was taken away by the knife, and the part healed favourably. She returned to the hospital in five months after; the glands in the groin of the same side being enormously enlarged, and all the structures in the inguinal region participating in the encephaloid degeneration. This creature died before the end of the seventh month after the operation, of repeated and profuse hæmorrhages.

Now the cases which I have given are examples of only one condition of the skin preparatory to ulceration and malignancy; that is, when there exists an indurated warty tumour, and this I conceive to have a cancerous tendency, *ab initio*. The small growth may be unproductive of inconvenience for years, until irritated, as illustrated in many of the cases which I have adduced; then the characteristic pain, sharp and lancinating, never entirely deserts it; ulceration sets in, making breaches round its base, and proceeds to the detachment of the warty surface. During this time, a thin fluid exudes from underneath; hard firm granulations are thrown up from an indurated base, not rising very high, yet presenting a mammillated surface, far denser than the interior of the projecting nodules. The destructive process which I have endeavoured to describe and elucidate by the foregoing cases, presents to the inquirer two very striking characteristics, and essentially belonging to it—1st, that when once the ulcerative process is set up, there is never any amelioration, ever so temporary, no attempt at cicatrization; and 2nd, the great liability of the appearance of encephaloid disease, either in the site of the original tumour or in the line of the absorbents, returning from its position. Here, then, are two marked differences as to results between it and the condition to which the term *noli me tangere* is applied, and to the *destructive ulceration* most accurately described by Dr. Jacob. Of this latter disease, I present to the Society this highly painted cast to contrast with those I have already exhibited. It shows well the characters of the disease as recorded by that gentleman. In this instance, though nearly half the scalp was destroyed, though inroads had been made by the disease to a considerable extent on the side and posterior part of the neck, the ear nearly detached, large vessels exposed, coated by small granulations, and sealed up against the passage of blood—yet, I say, with this amount of ulceration and death of parts around, the neighbouring glands did not participate in or suffer contamination.

In the cases Nos. 1, 2, and 3, the germ of disease lay, as it were, innocuous; its malignant tendency did not manifest itself until a very advanced period of life, at the respective ages of 52, 70, and 65; while in the cases Nos. 4, 5, and 6, it was ushered into existence at a much earlier age, 19, 28, and 24; while in Mr. Wardrop's case, the subject, a little girl, was only 12 years old.

It is remarkable, too, that once the ulceration was fairly established in the primary tumour, true encephaloid disease rapidly sprung up either in its site or in its immediate locality, with the exception of case No. 4, successfully extirpated. Again, in every instance which I have recorded, all the changes were brought about more speedily, and death followed more quickly, in proportion to the youth of the patient.

The inferences deducible from the results of these several cases, relative to treatment, point to the practical precept of early extirpation; we have evidence of its beneficial results in case No. 4, though ulceration, with its characteristic attendant symptoms, had just manifested themselves; the part was excised, the wound healed, and there has been no return of the disease, though a period of over three years has now elapsed.

In cases Nos. 2, 3, 5, and 6, the operation, I conceive, was had recourse to after the lymphatics and capillaries were charged with the product of the cancerous alteration; and though in some instances the wounds readily healed, yet in a short time the secondary results, the effects of the absorption, manifested themselves in the form of encephaloid disease. So firmly convinced am I of the line of treatment to be adopted in these cases, that I would advise all warts, when situated on the face or elsewhere, to be removed by the knife as early as possible, no matter how youthful the patient may be, as they all have a tendency in advancing years to degenerate in the manner which I have endeavoured to represent and elucidate.

Dr. Beatty thought that the cases brought under the notice of the Society that evening by Mr. Butcher, were both instructive and interesting in the highest degree, and said he fully concurred in his concluding observation, which should be borne in mind by every person who was likely to encounter those remarkable affections—namely, that a suspicious looking wart, especially on the face, should not be tampered with by attempting to effect a cure, but should be extirpated with the least possible delay. The remarks of Mr. Butcher had brought to his recollection the case of an acquaintance of his own, a very handsome young lady, who had upon her right cheek a wart of a very suspicious nature. Meeting her in the street one day, he asked her about it, and she informed him that it was a thing of no consequence whatever, and that her apothecary was daily in the habit of applying caustic to the wart with a view of curing it. He advised her to go to some eminent surgeon and have it removed; she took his advice; the wart was extirpated, and from that day to the present there was no return of the disease. But if she had permitted more time to pass without the removal of the excrescence, she would in all probability be now in the condition of one of the unfortunate patients described by Mr. Butcher in his interesting communication.

Dr. Jacob believed the cases adduced by Mr. Butcher to be well worthy the consideration of the profession; and trusted that they would have the effect of calling attention to the subject, as it might perhaps lead to a more distinct arrangement of these affections, than had been hitherto made. Last year he (Dr. Jacob) exhibited to the Society a case in which he had extirpated a tumour of a malignant nature from the orbit, and as such a case must be watched with great care, of course he kept the patient within view. It was one of carcinomatous tumour of the orbit, with encephaloid growth engrafted upon it. The poor man had since come back to him with a return of the disease, a great development of encephaloid structure having taken place in the orbit and on the side of the head. The instructive question in those cases was, whether they ought or ought not to extirpate the disease. Eighteen months had gone by since the tumour was removed in the case to which he referred; and therefore he thought that the argument for the operation amounted to this, that the man's life was prolonged, though not saved by it.

ENCEPHALOID TUMOUR OF THE ABDOMEN IN A VERY YOUNG CHILD.

By Dr. Banon.

Dr. Banon requested the attention of the Society to a somewhat remarkable instance of encephaloid disease which he had recently met with in a child of about 13 months old. At that late hour he would do little more than exhibit to the Society the morbid specimen, and give a short history of the case. About four months after birth the child was first seen by Mr. Packenham, who then observed

a slight swelling immediately below the liver, and apparently so connected with it as to give rise to the idea that it was owing to an enlargement of that organ. The swelling, however, soon increased in size, and passed on towards the umbilical and epigastric regions, so as in some months to distend the abdominal cavity completely. This was the child's state when Dr. Banon first saw her with his friend Mr. Packenham. At this time, though the little patient took a large quantity of nourishment, it lost flesh considerably, and strength. It did not, however, appear to suffer pain in the slightest degree until the last six weeks of its life, when the action of the bowels caused some suffering, owing to the mechanical obstruction created by the growth of the tumour. It was evident that the nutritive function was from the same cause seriously interfered with, from the great emaciation present.

The appearance of the abdomen was remarkable. At some points below the umbilicus examination gave the idea of fluctuation, and on afterwards examining the tumour, the portions of it corresponding to these points were found to be composed of pulpy, brain-like matter in almost a semi-fluid state.

The child at length began to suffer from dyspnœa of a severe character. Respiration could only be heard in the upper part of the thorax into which the lungs had been pressed by the growth of the tumour. The rest of the thorax was dull on percussion. The heart had been displaced upwards, and to the left side, and in this state the little patient sank.

On opening the abdominal cavity the enormous mass now presented, showed itself. It presented all the usual characters of the encephaloid form of cancer, which it was unnecessary for him here to enumerate; and also the nucleated cells and minute arrangement of structure peculiar to these growths were satisfactorily recognized in this case, under the microscope, by Dr. Carte. Dr. Banon, before concluding, would refer to the connexions of this tumour, and to the probable region from which it originated. In front the cæcum and colon are closely adherent to the tumour in their whole extent, and above it is intimately attached to the liver at its transverse fissure. Behind, where the disease most probably first sprung from, the tumour is connected with the cellular tissue in front of the spine and right crus of the diaphragm, and thence passed forwards between the layers of the mesocolon until it became attached, as before mentioned, to the cæcum and colon. The disease when it thus originates is termed "the post-peritoneal cancer." It is more than probable that the disease in this case commenced at a very early period of life, perhaps before birth. At the time Mr. Packenham saw the child it was but four months old, and even then the disease had so far advanced as to produce an external swelling. The right kidney and lower lobe of the right lung became secondarily affected by the disease. In the pelvis of the former and the tissue of the latter a considerable deposition of encephaloid matter has taken place.

Sir J. Murray considered the case one of very great interest, particularly from its occurring in so young a child. He begged to ask Dr. Banon to mention the exact age of the child at the time of its death?

Dr. Banon believed the child was about 13 months old at its death—at least so he was told by the lady who was the mother of the child, and from its appearance he was quite sure it was not older. He agreed with Sir James in thinking that the extent and rapidity of the growth of the tumour in so young a child was a remarkable circumstance—at the same time, that all pathologists were aware of the great tendency in this form of malignant disease to attain enormous magnitude, he (Dr. B.) had never seen a tumour of the kind at all approaching the size of this in so young a patient. It may also be worth remarking, that more than one pathologist has observed that malignant disease originating in the post-peritoneal cellular tissue is peculiarly apt to run its course, as in this instance, without directly causing pain to the patient.

CASE OF EXTENSIVE ENCEPHALOID DISEASE IN THE ABDOMEN.

Dr. Bellingham said, in connexion with the subject of malignant disease, he would exhibit a recent specimen of encephaloid deposit in the abdomen, taken from a subject whom he had examined that morning, which appeared to be remarkable for the rapidity with which it had been developed.

The patient, a French woman, unmarried, ætat. 56, was admitted into St. Vincent's Hospital, under his care, Feb. 14, 1852. She stated that she had been seriously ill only two months, and gave the following account of her illness. About two months before last Christmas, after walking a distance, she observed a small tumour in the left groin, accompanied by some pain; very soon afterwards she noticed a swelling above the pubis towards the left side, which has gradually increased, and now forms a considerable swelling. A month ago she began to suffer from urinary irritation. The ankles are œdematous for the last fortnight.

On examination, the abdomen was tumid and tense, with blue veins coursing over it. Below the umbilicus, and towards the left side, the edge of a solid tumour could be felt reaching from near the umbilicus to the left inguinal region, and extending across the pubis; handling it did not cause much pain. She laboured under irritative fever, was much emaciated, and suffered considerable pain in passing urine. She gradually sank, and died early this morning.

On examination, the large tumour felt during life below the umbilicus was found to consist of a mass of encephaloid involving the bladder and uterus, and diminishing considerably the capacity of the former. An enormous number of tumours of the same character, and of every variety of size, are seen in connexion with the omentum, the mesentery, and the intestines. The liver is small, apparently healthy, and quite free from every morbid deposit.

CASE OF PAINFUL SUBCUTANEOUS TUMOUR.

Dr. Bellingham said before sitting down he would take the opportunity of exhibiting a little encysted tumour which he had removed a day or two before, and which contrasted remarkably with the morbid specimen upon the table; while the latter had been of rapid growth, in this the growth had been remarkably slow; and while the large encephaloid mass had not been the seat of very great pain, the little tumour in his hand had been the source of the most intense suffering. This tumour was familiar to surgeons as the "painful subcutaneous tumour," first noticed, he believed, by Cheselden, and subsequently very accurately described by Dupuytren.

The patient, an unmarried female, aged 27, was admitted into St. Vincent's Hospital, under his care, February 28, 1852. She stated that about twelve years ago she felt a little kernel, like a pea, under the skin at the inside of the left leg, about three inches above the ankle; she had no pain but an occasional stitch in it. It became, however, eventually so painful, that eight years ago she submitted to its excision; the pain had a burning character, she compared it to a hot iron, which shot from the part, up the left leg and thigh, to the left side of the chest; the pain lasted sometimes an hour, sometimes two, sometimes there was an interval of a week without any return; it was always worse when she remained quiet, and was relieved by exercise.

She remained free from pain for six months after the operation, when the tumour again made its appearance; it has now the shape and size of a bean; is adherent to the skin; the surface has a whitish colour with a tinge of blue resembling cartilage; it is excessively painful to the slightest touch, and the integuments below it are likewise painful to the touch.

As the tumour was adherent to the skin, an elliptical portion of the integuments was removed with it, and the pain instantly ceased on its extirpation. On making a section of the tumour it cut like cartilage, which it resembled also in appearance; the cut surface presented a smooth homogeneous appearance. Dr. Carte had the kindness to examine it microscopically; it exhibited the characters of cartilage, but none of malignant disease.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

A PAPER was read, entitled—

VACCINATION TESTED BY THE EXPERIENCE OF HALF A CENTURY.

By Dr. GEORGE GREGORY.

The author commenced by observing that variolous inoculation was first heard of at Constantinople, in 1700, but was not practised in England till 1721, and did not become general till 1750. In 1746 the Small-Pox and Inoculation Hospital was established; and from this period variolous inoculation made favourable progress in the good opinion of the public throughout England. In France, however, during the same period, it was met with neglect, notwithstanding the efforts of De La Condamine to convince his countrymen of the merits of inoculation; and prejudice extended so far, that the parliament of Paris, in 1763, prohibited the practice of variolous inoculation within the walls of that metropolis. The author then proceeded to notice the twofold object with which inoculation was performed—first, to banish from the mind all anxiety as to the taking of small-pox in after-life, by giving it at once; and secondly, to ensure a mild form of the disease, free at least from secondary fever. Inoculation was eminently successful in fulfilling and attaining these objects. Nevertheless it undoubtedly had its disadvantages: it was essential to practise it in early life, before the infantine constitution could be known; and it thus often lighted up the dormant embers of scrofula. In 1798 the practice of variolous inoculation had been tested by the experience of half a century. In this year Jenner published his first treatise on Vaccine Inoculation, the advantages of which were at once confidently proclaimed; and in the following year seventy-three of the most eminent physicians and surgeons of the metropolis had signed a document, purporting "that persons who have had the cow-pox are perfectly secure from the future infection of the small-pox." The first claims of Jenner in favour of vaccination were singularly modest; but in 1802, he announced to the House of Commons—first, "that vaccination is attended with the singularly beneficial effect of rendering, through life, the person so inoculated, perfectly secure from the infection of small-pox;" and secondly, "that vaccination had already checked the progress of the small-pox, and, from its nature, must finally annihilate that dreadful disorder." The quantity of small-pox that still prevails, and the practice of revaccination almost universal, lead to the conclusion, that these broadly urged claims in favour of vaccination, have not been substantiated. Fifty years have passed since Jenner petitioned parliament; and the author proposed by the experience of this half century, to test the merits of vaccination. But first, what is understood by vaccination? Something prophylactic of small-pox; or something identical with small-pox? Cow-pox is a disease *sui generis*, and it cannot be said that he who has undergone vaccination has had small-pox in a mild form. A certain relationship exists between the two; but though variola by passing through the cow becomes cow-pox; yet cow-pox has never, in its turn, been converted into small-pox. Cow-pox and small-pox are, at all times, and in all countries, clearly and readily distinguishable. The object of inoculation was to give the disease of small-pox, not to prevent it. The object of vaccination is to prevent, not to give, small pox. Recurring small-pox, and small-pox after vaccination, are not merely different from each other, but actually opposed to each other. "If a person inoculated in childhood contracts small-pox in adult life, he suffers small-pox a second time, but a person taking small-pox after vaccination, takes the disease for the first time." The enemies of inoculation, as well as the supporters of vaccination, had severally taken their stand on recurrent or secondary small-pox. De La Condamine declared that not one person in 10,000 ever took small-pox a second time. The fate of Louis XV. was alluded to, and it was shown that the king's disease in early life (1724) was not small-pox, but a sharp yet brief attack of fever: that living in the constant dread of small-pox his distrust of inoculation was fearfully chastised by his death under a most aggravated attack of confluent small-pox. The author then noticed the extreme rarity of recurrent small-pox. The Transactions of the Society, extending through a period of forty-seven years, contained only one solitary case of recurrent small-pox. In many cases of so called secondary small-pox, the evidence of antecedent variola could not be relied on, as a case narrated in the *Edinburgh Medical and Surgical Journal*, October, 1818, clearly established. Many of the cases which the author had inquired into, were equally undeserving of credit. To arrive at a trustworthy conclusion, the details of both attacks should be carefully given. Very few medical men have in such cases witnessed both the primary and secondary seizure, and the author emphatically expresses himself as thoroughly convinced that the recurrence of small-pox is among the most rare events in the annals of medicine. The author then contrasted the occurrence of small-pox after vaccination. The records of the Small-pox Hospital throw much light on this subject. The following is a summary of the statistical details appended to the paper:—During the last eleven years, 4092 persons have been admitted into the hospital, having small-pox, of whom 2168 had been vaccinated, and 1924 were unvaccinated: more than one-half of those admitted had been vaccinated in early life. The majority were of adult age, a few between 9 and 15; but below the age of 9 scarcely any vaccinated person was admitted. It would thus appear that the susceptibility to the variolous miasm among vaccinated persons increases as life advances. The reverse of that happens in the unvaccinated. In 1850–51 the total number of cases of small-pox admitted was 976, of whom 162 died, being at the rate of 16 per cent. Of the 976 admitted, 41 were infants below the age of 5, all unprotected, of whom 22 died; 101 were children between 5 and 15, majority unvaccinated, of whom 25 or one-quarter died; 685 were adults from 15 to 30; 109 beyond that age. Total, 794 adults; the larger proportion of these had been vaccinated, of whom 115 died, or 14 per cent. Of the total number admitted—976,—613 professed to have been vaccinated; 569 exhibited cicatrices; of this latter section, 25 died, being at the rate of 4 per cent. In 1851 the proportion of persons admitted after vaccination amounted to 65 per cent.: it was only 44 per cent. in 1841. The increase is attributable to the extensive diffusion of vaccination. The mortality at the Small-pox Hospital during the last two years among the well vaccinated section has only slightly exceeded 4 per cent. The experience of half a century abundantly demonstrated that small-pox, though it has been largely controlled, will always abide among us, and that the notion of extirpating it is absurd and chimerical; and while acknowledging the immense benefits which have accrued from the splendid discovery of Jenner, vaccination had failed in establishing in the mind a confident feeling of security: it must be viewed as a beneficent provision of Nature, not for the extermination, but for the mitigation of small-pox. The author proceeded to show that inoculation had been abolished by act of parliament in 1840; and that, though rigidly observed, small-pox was just as prevalent now as then; that the quantity of small-pox had not in the smallest degree been affected by the prohibitory clauses of that act; that while this act prohibited inoculation, it did not render vaccination compulsory. Numbers therefore remained, as a pabulum whereon small-pox might prey. If the legislature could not or would not enforce vaccination, the restriction on inoculation should be removed. With proper precautions, inoculation might be safely adopted. Practised by other than authorised medical practitioners, it would of course be punishable as a misdemeanour by fine and imprisonment. With such restrictions it might be practised with perfect security. By far the larger proportion of mankind would continue to adopt the mild and safe process of vaccination; while others would prefer that measure which, occasioning a greater amount of immediate, abolished all prospective anxiety. Educated as the pre-

sent race of medical practitioners were, and acting, as they would act, under the supervision of a discerning press, both public and professional, they would exercise their judgment to the entire satisfaction, and ultimately to the great and permanent benefit of the country.

Mr. Grainger said he wished to explain the reasons which had induced him to take a part in the present discussion. It was doubtless known to many present that the Epidemiological Society had appointed a committee to investigate the important subject of vaccination and small-pox, of which it happened that he was chairman. That committee had collected some very important evidence and facts; they had received the opinions and experience of a large number of medical practitioners in different parts of England; and it was deemed essential that some of the more important results should be made known on the present occasion; and he was requested to act as the organ of the committee. He had also, at the request of the General Board of Health, made an inquiry two years ago into the state of vaccination in the metropolis; and an additional reason for speaking was the deep interests involved in regard to the public health. Mr. Grainger proceeded to remark that, although he had no practical acquaintance with the subject, and would not for an instant place his own judgment, as regarded the special points of the investigation in competition with that of Dr. Gregory; yet that as this was a question resting essentially on evidence and facts, any one accustomed to deal with such inquiries was competent to take part in the discussion. It was obvious that the important points raised by Dr. Gregory could not be determined by any amount of hospital experience; and yet it appeared that a considerable part of the data relied on were derived from the Small-pox Hospital.

Dr. Copland would only detain the Society a short time, and was not sorry that Mr. Grainger had objected to the statement he had made in his Dictionary, as he was desirous that the opinion therein expressed should receive attention and elicit further investigation. The opinion which he had expressed, notwithstanding the remarks made upon it by Mr. Grainger, had been derived from some experience on the subject, and from conversation with many who had had ample opportunities of coming to a conclusion upon the matter. His view had not, however, been recently taken: he had advanced a similar one thirty years ago, from his own experience in this and other countries. He adhered to the opinion which he had expressed on the point in 1823, and this opinion confirmed the results arrived at since by Dr. Gregory and others. If he had to choose, in the case of the nearest and dearest to him, between inoculation and vaccination, he should hesitate which to choose. He believed, however, that if all children between the third and sixth months were inoculated with the proper precautions, small-pox, as a secondary disease, would soon be unheard of. With respect to the 480 medical men who had supplied the Epidemiological Society with information, he would inquire what proportion this number bore to the great mass of the profession? He was aware that it required a certain degree of moral courage to come forward and express doubts on the benefits resulting from the practice of vaccination, and to assert that on many points connected with it a further or more minute investigation was required. Such, however, was the case. Vaccination had been so received as if it were a heresy to question its value in any way. Now, he doubted its efficacy to a certain extent, and on conviction had expressed his doubts. This question should be discussed on its merits, and not with views blinded by philanthropy. His remarks had applied to the subject of vaccination in all countries. He had stated facts, and if counter-facts were against him, he could only submit. He agreed in the main with Dr. Gregory. Mr. Grainger had alluded to the great amount of mortality in the Small pox Hospital; but it must be remembered that cases admitted there were mostly severe and dangerous; the milder ones were kept at home.

Dr. Webster said, as any remarks of Dr. Gregory respecting small-pox and vaccination, carried weight with the profession, he would crave permission to make one or two observations on the valuable paper just read, in which three important questions were discussed—namely, the inefficacy of cow-pox as a protection against variola; the advantages of inoculation as a substitute; and lastly, the great ravages of small-pox, notwithstanding extensive vaccination. Although he (Dr. Webster) acknowledged cow-pox was not an invariable protection against subsequent variola; nevertheless, when properly performed with good matter, and at the proper age, persons under such circumstances were quite as safe as if they had been previously inoculated. Indeed, he thought that many of the cases considered to be examples of small-pox occurring after vaccination, were often brought forward without sufficient proof. A scratch had been made upon a child's arm, and it was then said to be vaccinated, notwithstanding in many cases it could not be established that genuine cow-pox was ever communicated. Upon this point, reference might be made to Dr. Gregory's own charity, and should anything he now advanced appear erroneous, perhaps that gentleman would kindly supply deficiencies. Thus, by the published weekly returns of deaths, thirty patients died in the Small-pox Hospital during the last two months, of which five were reported protected. Now what was the evidence of such conclusions? He (Dr. Webster) would read the statements made regarding these examples, so that Fellows could judge for themselves. The first instance was aged 24, and had been vaccinated when young—"*one very small cicatrix, scarcely perceptible.*" The second was aged 25, and had been vaccinated at Strasbourg, in infancy—"*one very imperfect cicatrix.*" The third had attained her 18th year, and was vaccinated when young—"*one cicatrix scarcely perceptible.*" The fourth was aged 48, and had been vaccinated when young—"*two cicatrices, one good, the other very small;*" whilst the remaining death, or fifth, occurred in a patient aged 30, and had undergone vaccination, like all the others, when young—"*one cicatrix but very indistinct.*" Taking every circumstance into consideration, grave doubts must prevail regarding the genuineness of the vaccine disease originally produced. The true characteristic cicatrices were wanting; and as Dr. Gregory, always a good judge, attaches great importance to this feature, he (Dr. Webster) would not consider any of the examples here quoted as wholly free from suspicion. Similar inferences applied in some degree to the twenty cases of persons also stated to have died from variola, although all were said to be protected, amongst the total 283 deaths by small-pox, which took place throughout London, during January and February of the current year. Such testimony he thought incomplete. Mr. Grainger having adverted at some length to the employment of inoculation as a preventive of small-pox, he (Dr. Webster) would only observe that instances were on record of persons who had variola twice, and from which they ultimately died. The well-known case of Mr. Langford, in the fourth volume of the Medical Society's Transactions, might be quoted amongst others; and only last January, Mr. Mears of Lambeth, reported to the Registrar-General an instance of a child who died of small-pox, when three years old, although marked by an attack of that disease, which only occurred one year before. Other examples could be mentioned; indeed, they were more numerous than many practitioners perhaps imagined. Further, as to the notion that vaccination had not eradicated, or even much diminished the fatality of small-pox, Dr. Webster dissented from Dr. Gregory; seeing the mortality of small-pox was now very different, contrasted with former periods. For instance, one hundred years ago, when London was scarcely a third of the present size, 2625 persons died by variola, whereas, the average annual deaths from that cause ranged considerably under 1000 during the last fourteen years, being therefore less than one-eighth the previous amount. Lastly, were vaccination more extensively performed, as suggested by Mr. Grainger, he (Dr. Webster) really thought small-pox might be nearly eradicated; and having

obtained some experience on this subject, when physician to a vaccine institution, he must express his firm conviction in favour of the protective influence of cow-pox; and if vaccination is performed at the proper age, with good virus, which saturates the system thoroughly, whilst the usual pathognomonic signs have been recognized at the time and afterwards, then individuals may be considered as secure as it is possible to make them, even by inoculation.

Dr. Balfour said, that in the ten years, 1837–46, and out of an aggregate force of 255,000 soldiers serving in the united kingdom (and who are all presumed to be protected by vaccination or by small-pox previous to enlistment), 538 cases of small-pox were admitted into hospital, being in the ratio of 2 per 1000 of the strength annually; that of those, 52 died, or about 10 per cent. of the cases. The latter proportion was higher than that stated by Mr. Grainger as the result of the returns made by private practitioners, but is exactly the same as in the navy. The returns for a period of twelve years showed the proportion of deaths to cases, in the fleet serving in the Mediterranean, to be 10 per cent. The experience of the Royal Military Asylum appeared to him to bear strong evidence in favour of vaccination as a protective measure, for there had not been a single death from small-pox in that establishment during the last twenty-five years, among a constant average of 350 boys.

Dr. Gregory rose with some little hesitation, for it so happened that, with the exception of one of the observations made by Dr. Webster, nothing whatever had been said which related to his paper (hear, and laughter). It would be gratifying to him to meet the gentleman who had spoken so long in the rooms of the Epidemiological Society, and to discuss some of the minutiæ into which he had entered, and show their fallacies in relation to the matter. But he begged to say that this was the Royal Medical and Chirurgical Society, and not the Epidemiological Society (hear, hear). He had not been the least aware that an attempt would have been made to answer his paper by the reading of another emanating from the Epidemiological Society, and every word of which had been written before it was known what he (Dr. Gregory) had to say. Now, he would inquire whether this was a fair plan of proceeding towards the author of a paper read to this Society? He would only now advert to the observations of one or two gentlemen, to show how he had been misunderstood. Thus, Dr. Webster had said that he (Dr. Gregory) wished to substitute inoculation for vaccination. Now, he did no such thing; not a word, not even an allusion on this point, was to be found in his paper. On the contrary, it consisted of a simple statement of what took place formerly, and what was taking place now, in relation to vaccination. He also wished to show the benefit which would accrue to the country if parliament would cease to interfere in the matter of inoculation, and reconsider the determination it had come to in 1840—a determination which it had arrived at without any application having been made, either to the College of Physicians or Surgeons. It was a mere vote of parliament, and he contended that it was fair for us to consider if that vote met with the entire approbation of all parties. What was the position in which we now stood respecting the question of inoculation? Suppose an act of parliament passed which made it illegal to practise allopathy, and compelled us to follow the homœopathic method, should we not say that this was unfair? And yet the fact was, the law had for ten years past prohibited us from giving the ten grains of calomel, and insisted upon the administration of the infinitesimal dose (laughter). Parliament said that we were not to exercise our own judgments in the matter of inoculation, but that we must vaccinate; and yet this very parliament did not make vaccination compulsory on all persons, so that a great proportion of the population remained uninoculated and unvaccinated. He would just touch upon another point. What was the case just now in regard to vaccination? Was there a week passed that we were not applied to, to re-vaccinate persons? It had become, in fact, almost as usual as vaccination. Out of 140 persons applying from the 1st of January to be vaccinated, 60 of them were adults to be re-vaccinated. Did not this show that confidence in the protective power of vaccination was gone? The demand for re-vaccination was universal all over the country, from the palace even to the cottage. And why was this? The reason must be obvious to all. How did it happen, also, that after fifty years' trial of vaccination, the present discussion was taking place in this Society? Why, the heads of the Vaccination Board ignored re-vaccination, and it never had been brought before parliament; yet in Germany every person, and in Italy almost every person, was re-vaccinated. Why was this re-vaccination considered so essential in Germany, if, as Mr. Grainger had asserted, the protective power of vaccination was so clearly demonstrable? If this could be explained satisfactorily, he (Dr. Gregory) would acknowledge his error. This question was not to be settled by the opinions of 400 medical men, but by the experience of the whole world. If tested by such experience, the results he had arrived at would not be found so unwarranted as some would make it appear (hear, hear).

Mr. Grainger explained, in reference to the charge of unfairness advanced against him by Dr. Gregory, that he had met Dr. Gregory five or six weeks since, and stated to him that he should make some remarks on his views, which had been already before the public. He (Mr. G.) had referred to documentary evidence in support of his position, and he considered he had acted quite fair in the discussion (hear, hear).

Dr. Copland thought it would have been only courteous in Mr. Grainger to have informed him of his intended attack on the article in his Dictionary (laughter).

Mr. Grainger said that article was published, and was fairly open to criticism (hear, hear).—*Lancet.*

BIOLOGICAL SOCIETY OF PARIS.

ON THE PRESENCE OF A FREE ACID IN THE LUNGS DECOMPOSING THE ALKALINE CARBONATES OF THE BLOOD, AND THUS SETTING FREE THE CARBONIC ACID.

By M. Verdeil.

Amongst the results to which the experiments I have undertaken on the composition of the tissues and humours of the body, have led me, some are of such a nature as will interest the Society. I found in the parenchyma of the lungs of mammalia a distinct acid, which I have succeeded in obtaining in an isolated, perfectly pure and crystallized condition. The tissue of the lung of an animal lately killed did not sensibly redden blue turnsole paper. But when a mass of lung, cut up very fine, was macerated in warm water, it was found that the liquor possessed an acid reaction; which reaction became very manifest when the albumen and blood globules which coloured the liquid were coagulated.

This acidity is owing to a free acid in solution, in the juices with which the lungs are impregnated. This substance is formed of carbon, hydrogen, azote, and oxygen, in definite proportion. It crystallizes in brilliant needles, strongly reflecting the light. It is somewhat soluble in cold water, nearly insoluble in cold alcohol, but more soluble in boiling alcohol. Boiling absolute alcohol dissolves a very small quantity only. It is completely insoluble in ether. It possesses an acid reaction, and expels the carbonic acid from carbonate of potash and soda. When heated to 140 degrees, it does not lose water of crystallization; at a higher temperature it crepitates, becomes opaque, and is decomposed, giving rise to empyreumatic products; it forms a carbonaceous mass, which disappears completely, leaving no trace.

The parenchyma of the lungs therefore contains a free acid. We have also been able to prove that a portion of the acid which we extracted from the lungs, existed in the tissue as a salt of soda.

What must we conclude from the presence of an acid in the lungs? It is evident that, submitted to the general laws which govern chemical substances, this acid ought to decompose the alkaline carbonates carried by the blood; these, meeting in the lungs with the acid contained within

the tissues, ought to form a new salt of soda, and carbonic acid should be set free.

The pulmonary vesicles constantly secrete this acid, which, coming in contact with the carbonate of soda brought by the capillaries, the acid combines with the soda of the carbonate; the carbonic acid becomes free and passes off in respiration. The new salt of soda returns in the blood where we had found it, not free, but combined with the soda. This research was continued; all the characters of the acid and the phenomena of respiration concur to verify not a theory, but the fact, that an acid constantly secreted by the parietes of the pulmonary vesicles decomposes the carbonate of soda of the blood, and sets its carbonic acid free. This fact explains, amongst other physiological observations, the decomposition of the alkaline cyanurets and bicarbonates injected into the blood, when they arrive in the lungs, as M. Bernard has observed. —*Gazette Médicale de Paris.*

SUPPOSED VESICAL GONORRHŒA.

By R. G. Mayne, M.D., Surgeon of the Lock Hospital, Leeds.

By this name—and so far as the specific term is concerned, it is a very absurd one—is intended to be designated what I am induced to think was an example of so-called gonorrhœa, affecting the mucous membrane of the bladder; not simple cystitis, or what would be regarded as the sympathetic inflammatory affection caused by irritation in the urethra under that complaint, but actual *gonorrhœa* present in the bladder itself, producing from its internal surface a plentiful muco purulent or purulent discharge, in the same manner as it does from the urethra, and cured by the same treatment as is effectually pursued in ordinary attacks of that canal. I do not for a moment flatter myself that the correctness of this idea is beyond question; on the contrary, it cannot be more scrupulously regarded by others, than it has been hesitatingly adopted by me. Still it seemed to possess sufficient importance, at least to warrant its being given expression to, in order that it may be fairly weighed, and disposed of according to its value. I have had only this one case of a marked character, and have not met with any allusion to another in authors who have written on the general disease. I beg, therefore, to be allowed to state everything as it occurred to me, so as to afford the best illustration in my power of the manner in which the impression referred to was received.

Case.—On the 11th of October, I was sent for, to a considerable distance, to see a young man, who had been rigorously confined to his bed for above six weeks. Arrived at my destination, I of course objected to see the patient, except in the presence of his ordinary medical attendant; but was informed that that gentleman, having declined to meet one whom he did not know, had been dismissed. I found my new patient to be about 17 years of age, fair-complexioned, of the sanguineo-nervous temperament, sadly reduced in flesh, pallid, and emaciated; indeed as if he were in advanced consumption. I could get no medical history of the case, owing to the circumstance already alluded to. From the patient and his mother, however, I learned that he had been complaining since shortly before the period mentioned, of uneasiness in the loins, and slight tenderness over the region of the bladder, for which his adviser had enjoined strict confinement to bed; that he had taken much medicine without benefit, and thought that latterly he had been getting worse; that on some anxiety being expressed about his wasting condition, the medical attendant had called a highly respectable physician into consultation, who agreed with him, it appeared, both as to the case and its treatment; but what they may have considered to be the nature of the one, or upon what indication they pursued the other, was not shown to me. I only ascertained that the youth had passed *per urethram* a small calculus, some time before my having been called to him, and that thereupon a notion was imparted of there being probably another stone in the bladder, as the source of all the mischief. I further learned, that, for a considerable time past, his urine, on being allowed to rest for a few hours, had always deposited a large quantity of thick yellowish substance, amounting to about a fourth or fifth of its quantity, which, on agitation, again mixed thoroughly with the urine, but if undisturbed seemed adherent to the bottom of the vessel; that inflammation of the bladder was reputed to be a part of his ailment, for which, indeed, he had had a blister applied over the sacrum, but without producing the slightest amendment; and that this formed the reason (as they believed) why he should not leave his bed, on pain of serious evils. The patient informed me that he had contracted gonorrhœa three months before, or about six weeks ere he was thrown upon his bed, and had been treated for it by the same medical man who had latterly attended him for several weeks; but was now as bad as ever. Having patiently listened to these imperfect statements, I began to scrutinise for myself.

In all that had been recounted, I could discover no good cause for the spare diet, confinement to bed or even to the house, nauseated stomach, and their combined wasting effects. I found no tenderness, either of the renal or sacral regions, and only very slight uneasiness over the bladder, when strongly pressed on; but no other ailment whatever, save the urethral affection. There was neither cough, ache, nor pain; he could sit up, turn or move about in bed, or get out of it with such alacrity as the dwindled condition of his legs would allow, but without the slightest indication of suffering. Some difficulty was experienced in attempting to rouse him into a cheerful mood, so impressed was his mind with the notion of a fatal issue. When told to rise, get himself dressed, and take a little nourishing refreshment,—then, as the day was fine, to go out for a walk with some friend's help, return to a good meal, and repeat the same course as often as he pleased, only avoiding stimulating liquors, he looked bewildered and incredulous, as if he were mocked. Fixed as his whole thoughts had been upon a fate very different, he could scarcely believe me serious; and in fact, as I afterwards learned, did not dare venture out of bed, till after long persuasion, on the following day. From that date, however, he persevered, rapidly improving in general health, without a bad symptom; on the third day afterwards, as will be seen, he paid me a visit at my own house.

So far as my patient and his mother understood the former medical attendant's opinion of the case, and the treatment pursued, his complaints were cystitis, or inflammation of the bladder, dependent or not upon the assumed presence of another stone in the bladder, and the urethral discharge. Of the first, there existed no marked symptom save the large deposit in the urine; which, however, if really the result of inflammation, was only likely to be an effect of chronic inflammation of long standing, and that it could not, in this case, be. The second was altogether conjectural. The existence of the last alone was indubitably demonstrable. I passed a sound into the bladder without being able to detect the presence of a calculus, but found the neck to be highly irritable; and my patient informed me, he had been for some time annoyed by an urgent call to pass his urine several times in the course of the night. On minute inquiry, I learned that eighteen months previously he had experienced slight uneasiness in the bladder, and noticed some turbidity of the urine, both of which had disappeared on his going to reside for a time with some friends in Ireland; but that soon after his return home, which occurred shortly before he contracted the gonorrhœa, the uneasy sensations about the bladder, and the frequent desire to void its contents, began to be again felt. I further ascertained, that he had been treated for the urethral discharge by copaiba in some form, with slight improvement, for about a month before taking to bed, and for some time subsequently; that he had taken medicines, of one kind and another, till his stomach would bear no more; the deposit in the urine, which gradually appeared since the gonorrhœal attack, had latterly greatly increased; and his mother, seeing him getting daily worse, weaker, and thinner, had resolved on changing his medical attendant. His age and evidently sound constitution, together with

the information obtained, precluding all idea of chronic cystitis as the cause of the copious deposit, it seemed wholly unaccountable, except on the ground assumed in the outset, that the case was one of so-called gonorrhœa affecting the mucous coat of the bladder.

I explained my views, as well as was practicable, and readily obtained consent to the employment of any measures which might be judged necessary. It was arranged that the patient should come to me in three days hence for the purpose of commencing treatment.

October 14th. The patient came according to appointment. I introduced into the urethra, and down into the neck of the bladder, a gum bougie, smeared with a strong and firm caustic ointment—fifteen grains of the nitrate of silver to one drachm of simple ointment—and desired the youth to return to me in a week; but did not yet supply him with any internal medicine, because of the weak state of his stomach. 20th. He returned with a slight discharge, but as the entire effect of the caustic might not have passed off, nothing further was done. 25th. The discharge had somewhat increased, and returned to a more yellow colour, a circumstance contrary to usual experience of the abortive treatment thus pursued in the case of males. I therefore again applied the anointed bougie, as efficiently as I could, and desired him to come back on the fifth day thence, in order to commence with the use of medicine, which his bodily condition now fully permitted. 30th. He came accordingly, and took with him a week's supply of a copaibal mixture, containing four drachms of the balsam, to eight ounces of water, one ounce for a dose, three times a day.

November 7th. The discharge was still persistent; had positively again appeared, after its second temporary subsidence having been effected by the caustic ointment. The occurrence was almost unprecedented and inexplicable, save by the diagnosis formed, which it thus unequivocally confirmed. In no other way was it conceivable that the urethral membrane, cured by the caustic application, as happens in other cases nearly without exception, should become again diseased, than that it had been reinfected by being subjected to the contagious influence of the mucopurulent or purulent discharge of the unhealthy vesical membrane. Acting upon this opinion, and judging that the copaiba had not yet had time (only one week) to make any very decided impression on the state of the bladder, I enjoined its steady continuance, and once more introduced the anointed bougie. 14th. On his appearance to-day, he reported that he had only seen a little watery discharge, and that the condition of the urine was greatly improved, the proportion of deposit being considerably reduced; as also the irritability of the neck of the bladder was less, so that he was not so often troubled to pass his urine. Directed to continue the copaiba. 21st. No discharge, but about a drop, or half a drop of transparent fluid (which is, in fact, the natural secretion in a state of health), and the deposit still less. 28th. Greatly improved in every respect, the deposit having diminished down to a mere shadow of a cloud, what would not have attracted notice in the case of any one who had not been similarly complaining. My patient was become as stout, full-faced, and comfortable in spirits and bodily aspect, as could be wished. He and his friends were desirous that he should speedily again repair to Ireland, where a situation of some importance was promised him; and from a fear of relapse by stopping the treatment even a day too soon, I proposed, as a safeguard, to act on the mucous membrane of the bladder, by injecting a caustic solution into the viscus itself; and it was agreed that my patient should pass a few days in Leeds for this purpose.

December 9th. He and his mother called to inform me of their arrival, and gave me their address, the former being quite well in all respects, but nevertheless resolved to undergo what had been proposed. 10th. I waited upon him in his new abode, and having made him empty the bladder, I injected into it by means of a double catheter, a solution of one drachm of the nitrate of silver in four ounces of distilled water. When it had flowed out, I introduced a dilution of one drachm of tincture of opium in four ounces of water in its place, with the object of reducing any slight portion of the caustic injection that might remain, and of allaying undue irritation. 11th. Kept him to bed, having found all satisfactory. 12th. The same; no inconvenience from the caustic injection, save a little smarting on micturition. 13th. The same; I desired him to get up, but this he chose to defer for another day. 14th. Walked out; free from all uneasiness. 15th, 16th, 17th. No inconvenience whatever; urine clear; no desire to get up in the night; in perfect health. 18th. Took his departure, strong and robust; as compared with his condition nine weeks before, like one snatched from death.

From the history of this case here given, I have ventured to draw the following conclusions:—

1. That it was one of so-called *gonorrhœa*, directly affecting the entire mucous membrane of the bladder; and therefore different from those comparatively rare complications of that affection with cystitis,—that is, simple, or as sometimes named, sympathetic inflammation of the bladder, arising from the irritation of urethral gonorrhœa, from acrid substances taken into the system for its cure, which act injuriously on the bladder, as cantharides, terebinthinate substances, or balsams; or from irritating injections used too frequently or pushed too far.

2. That the preceding view seems to be borne out by the history, so far as ascertained; by the case having obstinately resisted, and even become worse, under all means attempted as remedies for cystitis, or whatever else it was supposed to be, during the six weeks preceding the adoption of treatment pursued in accordance with that view; and by the perfect success of such treatment; also by the fact, just alluded to, that cystitis is sometimes produced by the balsams taken into the system for the cure of gonorrhœa; therefore, had this been a case of simple inflammation of the bladder, it would have been aggravated by the copaiba, so freely exhibited as it was; whereas it steadily yielded, like a case of urethral gonorrhœa, to the curative influence of the balsam. Sir Astley Cooper pointed out in his lectures a mucous disease of the bladder, in which there was an enormous quantity of ropy mucus discharged with the urine, and for which he said—"The best remedy, however, is the balsam of copaiba." In the present case, however, the youth and healthy constitution of the patient were unfavourable to the supposition of a mere mucous disease of the bladder, so extensive and so suddenly lighted up, and spontaneously; for Sir A. Cooper does not state it as a consequence of gonorrhœa; while on the other hand, the view taken is supported by the fact of the previously contracted urethral affection, by the discharge from the bladder having, to all seeming, been contagious, so as twice to *reinfect* the urethral membrane; and by this renewing of the infection having entirely ceased when the disease was controlled in the bladder itself. Again, had it been merely a mucous disease, would not the qualified general practitioner and the experienced physician who preceded me, have been sure to detect and easily cure an ailment so very simple?

3. The *rationale* of the encroachment of gonorrhœa upon the bladder—a circumstance certainly not common; for, so far as I am aware, it is not mentioned by authors, unless we may consider that the case or cases referred to by Sir Astley Cooper had such an origin; and the present forms the only example in my own practice—may be conceived thus:—The patient had suffered once (eighteen months) before, from slight inflammation of the bladder, which was easily subdued; and he was again the subject of a similar attack (whatever the true nature and causes of that affection) at the very time when he contracted the urethral gonorrhœa. He had at that time to get up in the night to pass his urine, and had a considerable stinging sensation, particularly towards the root of the penis or neck of the bladder. This, I conceive, constituted the most favourable condition of parts for inducing the progressive advancement of gonorrhœal infection. The contagious muco-

purulent or purulent discharge would glide along, invited, as it were, by, and mingling with the heightened secretion of the predisposed surfaces, to or into the neck; from whence in the same manner, as from the smallest portion accidentally placed upon the border of the conjunctival membrane in gonorrhœal conjunctivitis or upon the extreme margin of the urethral membrane, it would extend, slowly yet surely, over the whole.

4. The case tends to show that while the affection, which for want of a better term, I have called vesical gonorrhœa, cannot be cured by the means to be relied on (and, I must believe, put in exercise by my precursors on the occasion in question) in cystitis, or simple inflammation of the bladder, howsoever caused, it is directly amenable to the ordinary treatment of common gonorrhœa; clearly indicating, not only their identity, but also that, contrary to the opinion of M. Ricord and certain of his ardent followers, there *is* a specific quality in the characteristic muco-purulent or purulent discharge of so-called gonorrhœa, which distinguishes it completely from the suppurative effect of simple inflammation.—*London Jour. of Med.*

REVIEWS AND NOTICES OF BOOKS.

RESEARCHES INTO THE PATHOLOGY AND TREATMENT OF DEFORMITIES IN THE HUMAN BODY. By John Bishop, F.R.S., Member of the Council of the Royal College of Surgeons of England, Consulting-Surgeon to the Northern Dispensary, &c. London. 1852. 8vo. pp. 266.

Mr. Bishop is already favourably known to the profession by his papers upon the subject of Deformities, published in the *Lancet*. In this treatise he has embodied the greater portion of what has appeared in the pages of that journal, adding such further details as his additional experience suggested; and we are glad to observe that the fault which applies to too many works upon this subject—viz., that they are addressed rather to the public than the profession, does not apply to his treatise, which is intended exclusively for the profession.

The subject of deformities has been, the author observes, "too often treated by medical men with neglect, as one of an inferior order, and devolving on the mere mechanician, to whom, in effect, the problem is commonly proposed for solution—Given a distortion, to discover an instrument that will cure it. It need not, therefore, excite surprise to find, as will be shown, that means have frequently been employed, even by respectable practitioners, entirely at variance with the intrinsic nature of the case; so that, with the expectation of giving relief, useless torture or deplorable mutilation has, in many instances, been inflicted."

"The subject of deformity is here proved, on the contrary, to require the most careful research, and to present a field for the most elaborate mathematical investigation. The principles of treatment recommended are based on mechanical and dynamical laws, which have received the assent of the most distinguished physical philosophers of the present day. It is, in fact, the wish and aim of the author to induce the members of the profession to advance from the employment in such cases of mere mechanical experiments, to a sound and judicious practice founded on scientific data."

Mr. Bishop, after some preliminary remarks, proceeds to consider, first, the properties of bone; followed by a sketch of the vertebral column, and remarks upon the properties of muscle. The author next calls attention to the circumstances which tend to produce curvatures of the spine, and distortions or deformities of other parts. In this place the various deformities of the knee and ankle-joints are considered, including the several forms of club-foot. The author's remarks upon the value of myotomy and tenotomy, as a mode of cure in these and similar affections, are much to the purpose.

"Surgeons, more especially of the German and French schools, finding it difficult to stretch contracted muscles, have adopted the plan of cutting through the muscles themselves, or their tendons. By this means, the parts held by the muscle are released, and it is found that after a longer or shorter time, the fleshy or tendinous portions reunite, although the points of attachment are at a greater distance than they were before the operation; they have therefore become elongated. . . . . .

It is probable that the tendon recovers its original strength, but not so the muscle; at least such is the opinion of many of the French surgeons, who say that the muscle so mutilated loses a portion of its force. This may easily be understood to be the case from the experiments of Schwann, who observed that the force of the muscle is at a maximum when it is in its greatest elongation, and at a minimum when it is in its greatest contraction; so that the forces of muscles, in different stages of their contraction, vary in some way directly as their lengths. Now, as the muscles after their division become shortened, and have no power to elongate themselves, their union must take place by the production of new matter, which fills up the interval between the divided parts. By this means, the muscles are lengthened without being stretched, and do not acquire the tonicity and extension of their normal state, and hence their loss of power.

. . . . . .

To prove the utility of the subcutaneous section of muscles and tendons, it is not enough to show that the operation may be performed with little pain, and trifling danger; although the truth is, that it is not so free from danger as Guérin and others suppose. The posterior tibial artery has been wounded in dividing the tendo-Achillis, and the internal plantar artery in dividing the plantar fascia. In both cases abscesses formed, and it was ultimately found necessary to tie the arteries. . . . . .

As muscles are incapable of elongating themselves, and although they oppose great resistance to being stretched, are, nevertheless, susceptible of elongation, it becomes an important subject of inquiry whether some mode of producing this effect may not be practicable without the necessity of subcutaneous sections. If a muscle is stretched by any force for a short period, it becomes contracted again as soon as the force is removed; but if the force is long applied, the muscle will not regain its primitive condition until after a lapse of time of greater or less duration, to be determined by future experiment. Now, there are, it is true, some organs so constituted, and some muscles so situated, that it is either difficult or impossible to apply a force sufficient to effect the object in view. . . . . When, however, the contracted muscles are situated in the back and lower extremities, we have ample means of promoting their extension; and in these cases, what excuse is there for dividing muscles and tendons which are only contracted mechanically? Is it rational to do this merely to lengthen them, when it is found that the same end can be accomplished by other and simpler means?

On a careful and rigid examination of the subject of myotomy and tenotomy, it appears that these operations cannot, in the majority of cases, be deemed expedient for the purpose of curing deformities, as nothing can be obtained from them which may not be effected by other and less objectionable means. The excepted cases, if any really exist, are strabismus and other analogous affections; but even these are to be regarded with great suspicion. The best surgeons of the French school have already decided against the practice, and few of our most eminent English surgeons adopt this empirical plan of mutilating the body."

The effects of caries, rickets, and mollities ossium in causing distortion, are next considered at some length. In the succeeding chapter, the author shows the necessity for the study of the human frame in order to treat deformities successfully; and he then notices in detail some of the plans recommended for this purpose, accompanied by figures of the apparatus which have been most extensively employed in cases of spinal curvature. "It is remarkable (Mr. Bishop observes), considering the attention that has been paid to the muscular powers which Nature has bestowed on the human body, how little these powers have been employed in attempts to correct distortions." "Hence we have a multitude of machines invented for the purpose of doing what they have never accomplished, in cases in which the only mechanism needed might have been found in the body itself; while in others, in which extraneous aid was required, that which was

employed has often been at variance with physiological and mechanical principles; so that, we find that in cases in which the causes of distortion are very dissimilar, the mechanism adopted to relieve them has been almost, if not entirely, the same."

"The various kinds of machinery just mentioned may be classed under three heads—namely, 1st, those designed to stretch the body, either in a horizontal or vertical position; 2nd, those which tend to prop the body and limbs; 3rd, those which have for their object the reclining the body, either obliquely or horizontally, in prone and supine positions."

In this chapter the author dwells at some length on the injurious effects of stays, under the heads "propping use of corsets or stays;" "their debilitating effects on the muscular system;" "their effects on respiration, circulation, and digestion;" "their effects on the human figure;" "their use dependent on ignorance and vanity." An idea must surely prevail, Mr. Bishop observes, that from an early period the human body is not a self-supporting machine, and is therefore in this respect inferior to the lower animals; whereas, in truth, the greater the freedom of muscular movement, the greater is the normal strength and power of the muscles to keep the body erect. "But let us inquire (he adds) into the actual effect of stays, especially when applied to growing persons between the periods of youth and adolescence; and let us take, for example, a young girl of from four to fourteen years of age." "Up to the first period, the parents usually allow the muscles to perform their natural office of controlling the attitudes, and of preserving the equilibrium of the body about its centre of gravity."

"When the child has acquired a perfect control over the various attitudes which the body commonly assumes in youth, when the muscles have been accustomed to freedom of motion, and when the erect position is maintained with perfect ease, then the parents usually encase the body in some kind of corset, which restrains the movements of the back within narrower limits than those to which it had been accustomed; the muscles are at the same time curtailed of their natural action, and lose a portion of their power, becoming less able to support the trunk steadily. In a short time after the application of the stays, the wearer feels unable to maintain the erect position comfortably without them; and after the lapse of a still greater period, by habitual use, these unnatural appendages to the human figure become apparently, though not really, as necessary to the individual as is the natural carapax to the tortoise. The injurious effects of stays, however, are not confined to their debilitating influence on those muscles which serve to keep the trunk erect; they extend to several other very important functions of the body. It is well known that the framework of the thorax is composed of an assemblage of bones and cartilages, which are articulated to each other in such a manner as to allow, during the respiratory processes, of very peculiar movements essential to a healthy state of the body. One of these movements—namely, that of inspiration, increases the horizontal section of the thorax; but since stays are usually composed of unyielding materials, the full expansion of the chest, and its normal and automatic movements, are impeded. When the stays are laced tightly round the body, under the erroneous idea of improving the figure, the natural areas of the thorax and abdomen are diminished, the viscera displaced, and the great vital functions of respiration, circulation, and digestion deranged."

In the chapter which succeeds, the relative advantages of the recumbent, supine, and prone posture in the treatment of deformities of the spine are discussed; followed by a summary of the author's views respecting the treatment of lateral curvature, and distortions of the lower extremities. The concluding chapter is headed "physical and psycho-physical treatment of children." We cannot delay upon the subject-matter of this chapter, but shall endeavour to make room for a single extract from the concluding portion:—

"When we take a survey of the vile machines that have been invented, and consider the amount of torment inflicted by them for no useful end—that patients have been subjected, often for years, to painful restraint, have incurred expense, and lost much precious time, all which has been borne with fortitude by the young and delicate, buoyed up by the fallacious hope of a happy result, and that muscles and tendons have been cut, and various other mutilations inflicted on a mechanism so beautiful and so perfect as that of the human body, in order to attain objects which such means could never accomplish, it must be acknowledged that this branch of surgery is in a most deplorable state. Almost every orthopœdic practitioner has hitherto employed some favourite machine for the treatment of distortion. The author does not intend to propose any new machinery, either for stretching, pulling, pushing, or propping the body; his aim being to dispel the illusion that such machines possess any value, by demonstrating their inefficiency in the majority of cases, and thus to pave the way for a more scientific and rational practice in this branch of surgery."

In concluding, we shall merely remark, that, of the many treatises which have issued from the press within the last few years upon the subject of deformities which we have had the opportunity of perusing, some are immeasurably behind the work before us, and none take a more correct or scientific view of the subject, or appear to be so well calculated to lead to an improved method of treatment.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MARCH 31, 1852.

A REAL CURIOSITY OF MEDICAL LITERATURE.

We had the following in type for preservation in that compartment of our archives which we devote to the "state papers" of the profession, but casting an eye accidentally over its contents, an unfortunate propensity to indulgence in a laugh so disturbed our editorial equilibrium, that for the life of us we could not recover composure sufficient to discharge so serious a duty. From the days of Rabelais to this unlucky hour, when our risibilities are thus provoked, the "sad and learned" section of our body has ever and anon called forth a similar unseemly expression of mirth, but seldom indeed has it more effectually done so as here. The effusion purports to be an address to the Lord Lieutenant, and was, we have no doubt, delivered as such; but even that association of it cannot restrain our inclination to give it the place in our columns to which it is entitled:—

"We, the President and Fellows of the King and Queen's College of Physicians in Ireland, have come to tender our homage to your Excellency as the chosen representative of our beloved and gracious Queen.

Nor are we less anxious to express our deep satisfaction at being placed under the authority of one who, descended from a long line of noble ancestors, and bearing an escutcheon blazoned with emblems which tell of royalty, and point to the chivalry of France and Scotland, comes here, we doubt not, faithfully to carry into operation that principle of action which springs from "trust in God, and good will towards man," which we gladly accept as our surest foundation for a high and heartfelt confidence that we shall be "Godly and quietly governed;" as it is also our best security for "the safety, honour, and welfare of our Sovereign and her dominions."

As Irishmen we rejoice to believe that, could we penetrate the inmost feeling of your Excellency's bosom, it would tell us that Irish hearts and Irish affections are there associated with a charm of such deep and tender influence, as will cause the sentiment, so richly deserved by one, to be, for her sake, extended to many.

Joyfully, also, do we recognize in your Excellency's appointment a pledge of the abandonment of that centralizing system whose blighting influence has already fallen so heavily upon this land, like some of those fatal diseases which waste and wither up the limbs, while giving to the body an unwieldy and unsound preponderance; and so we trustfully anticipate never to see those stately halls ungraced by a vice-

regal occupant prepared to emulate your Excellency's princely splendour.

We have now only to express our fervent hope that your Excellency may long enjoy among us here, in health and happiness, the high honour conferred upon you by our Sovereign."

Some may, perhaps, feel inclined rather to weep than laugh at this malaprop display of fulsome adulation, as angels themselves do when vain man, dressed in a little brief authority, plays such fantastic tricks; for truly such a public exhibition of imbecility is little suited to win that confidence which our profession requires. On second thoughts we begin ourselves to be serious too, touching the matter, seeing that we live in times when we cannot afford to be made ridiculous, even by implication. The Fellows of the College of Physicians on all occasions ostentatiously claim to be the representatives of the Physicians of Ireland (which it is scarcely necessary to say they are not), and when they thus, at a critical moment, lower the character of the body for common sense, it becomes absolutely necessary to repudiate the assumption. The LORD LIEUTENANT must be taught that the medical practitioners of Ireland are not composed of such materials as a perusal of this silly document might lead him to suppose, because such a misconception might prove most injurious at the present moment. He must, in fact, be informed that they have taste and judgment enough to prevent their committing such an absurdity. For several of the College of Physicians we entertain a high respect, and the majority we consider fair specimens of the medical genus, but we frankly confess that there are a few amongst them we cannot admire, neither can we compliment the body at large upon its tacit acquiescence in the very discreditable proceedings which have latterly disgraced the Medical School of Dublin. If the government and the public are to be impressed with a proper sense of the importance of the medical profession by them, it is not by the adoption of the suggestions of such men as these who penned this nonsense, or who, to gain their private ends, hesitate not to sacrifice the "honour, reputation, and dignity" of the medical profession by acts of an equivocal nature, and ridiculous efforts to attract the admiration of the vulgar. To the honest and sensible members of the College of Physicians, we venture to say that if they are to exercise any salutary influence on the destinies of the medical profession, the sooner they emancipate themselves from the obsolete rules of antiquated corporations, and abandon clandestine proceedings, the better. We also venture to say that the sooner they rely on their own resources the better too; for, to be dragged through the dirt by any other institution will not redound to their credit in the sequel.

AGITATING PLACEMAKERS IN THE FIELD AGAIN!

STRAWS in the air tell us which way the wind blows, and political litter is equally indicative of the currents which prevail in the placehunting world. In the House of Commons we see that a Southern Member has moved for a string of returns touching the Lunatic Asylums, and as we believe he knows nothing whatever about the matter, we come to the conclusion that he is only doing the work of others. Be this as it may, we have no doubt that the move is a prelude to a campaign similar to those which have closed with the passing of the last Medical Charities Act. The returns demanded are evidently called for by way of insinuation that the annual returns of the Inspectors are either imperfect or untrue; for whatever of importance is required has already been printed. The truth is, that the old placemaking spirit is as rife as ever, and the appetite of the placehunter by profession is as insatiable as heretofore; so we are in for another bout of "agitation" in this direction. Whether it be that some of the lunatic officials have cast the eyes of affection on the places and salaries of others in the department, or that the poor-law people are yearning after more of the loaves and fishes of "inspection," we cannot tell; but certain are we from this rustling under the straw that the old vermin are at work. Satisfied, however, that we have had enough of these doings for the present, we are determined to watch the movements of the parties concerned without intermission. This agitation for place is the curse of this country, and in no department has it been so mischievous as in ours. Never shall we have one hour's peace or rest, or one fair opportunity to bring the medical institutions into salutary operation, until the government resolutely repulses all candidates for office who found their claims on "agitation." We do not mean mere political agitation, although that has been the foundation of these proceedings, but placemaking agitation, which aims at the destruction of existing institutions, in order to appropriate the salaries of those displaced to the use of the agitatior.

While penning the above, additional proof is afforded us that the indomitable spirit to which we have been alluding still exists in all its pristine strength, although not perhaps directed in the channel to which we have been directing attention. The document, it is true, is an amusing proof of the ruling passion of its author, but there may be more at the bottom of the overture than simple people can well comprehend. Has the working of the Dispensary Act revived old hopes, or is there any "cross" at head quarters which encourages a return to ancient tactics? The cat's paw which subscribes the document has been dipped into a queer cream crock, but no one knows the luck of a dip in the dark:—

TO DENIS PHELAN, ESQ., INSPECTOR OF POOR-LAW UNIONS.

DEAR SIR,—Having learned that by recent arrangements, connected with the administration of the poor-laws, you have ceased to be the Medical Inspector of the Poor-law Unions of Ireland, and that your present duties are confined to the supervision of a northern district, as permanent inspector, we cannot permit the occasion to pass without giving expression to our regret at the cessation of that intercourse which has so long subsisted between us, and also to the grateful feelings of sincere respect, esteem, and affection, with which we have been inspired by your official conduct and personal kindness.

We are peculiarly qualified to appreciate the great difficulties of your official position during a protracted period of unexampled suffering, sickness, and mortality of the people of this country; and we feel great satisfaction in acknowledging that while these difficulties would be calculated to convert the relation subsisting between us and a less judicious and less kind inspector into a state of antagonism, your supervision was only productive to us of support, encouragement, and hope in the discharge of our arduous duties.

We cannot forget that while throughout this afflicting visitation your frequent inspections of the several union hospitals under our care were conducted in the most efficient manner, and with the strictest and most conscientious regard for the public interest, your conduct towards us was uniformly characterised by the most gentlemanlike courtesy and considerate kindness, and that at all times we were indebted to your great experience and mature judgment for friendly advice and valuable assistance.

Permit us, incidentally, to acknowledge the eminent services you have rendered to our profession and the public, both before and after your connexion with the poor-law commission, by your valuable writings and able reports, which we do not hesitate to say form the groundwork of the great improve-

ments which are contemplated, or have already taken place, in the medical institutions of this kingdom.

We now take leave of you with sincere regret. Our several positions render it probable that we shall seldom have the pleasure of meeting you; but be assured, very dear sir, that those feelings of attachment, respect, and personal friendship which your continuous kindness has produced, will be ever cherished by us, and that you bear with you to the new sphere of your labours, our heartfelt wishes for your happiness.

CHARLES HALPIN, Secretary to Committee.

ROYAL COLLEGE OF SURGEONS.

His Excellency the Lord Lieutenant received a deputation of the President, Members of Council, and Fellows of this College on the 24th inst., when the following address was presented to him by that body:—

To his Excellency Archibald William, Earl of Eglinton, Lord Lieutenant General, and General Governor of Ireland, &c.

MAY IT PLEASE YOUR EXCELLENCY,—We, the President, Council, and Fellows of the Royal College of Surgeons, beg leave to approach your Excellency to congratulate you upon your arrival in Ireland, and to assure you that we are much gratified at having an opportunity afforded us of thus expressing our feelings of respect.

We beg leave also to assure your Excellency that we shall at all times be prepared to contribute, by every means in our power, towards advancing the welfare of the public service in our particular department, and that we shall be glad to receive from the government such suggestions, as it may think proper to make, to enable us to carry this, our determination, into effect.

We are also anxious to avail ourselves of the present occasion to solicit, most respectfully, the attention of your Excellency to the state of the medical institutions of this country, and to express a hope that you may be pleased to extend to our profession that protection and support which, from its public services, it is entitled to claim.

LEONARD TRANT, President.
ALEXANDER READ, Secretary.

His Excellency replied as follows:—

MR. PRESIDENT AND GENTLEMEN,—I feel much satisfaction at receiving these expressions of regard from a body so respectable and so useful to the community.

Men of your profession have, perhaps more than any other, been found ready and able to do their duty under the greatest difficulties and the most trying circumstances, and I well know that the Surgeons of Ireland, inferior as they are to none in ability, will never be found wanting where the public service is in question.

I will give my best attention to the state of the medical institutions in this country, and bestow that interest on the subject which its importance so well deserves.

The following were of the deputation:—

President—Mr. Leonard Trant. *Vice-President*—Mr. E. Hutton. *Secretary*—Mr. Alexander Read.

Members of Council—Mr. Cusack, Mr. Jacob, Mr. Tagert, Mr. Williams, Mr. Ellis, Mr. Beatty, Mr. Rynd, Mr. Adams, Mr. Barker, Mr. Colles, Mr. Lipsett, Mr. Corr, Mr. Bevan, Mr. Irvine, Mr. Hughes.

Secretary to Council—Mr. H. Maunsell.

Fellows—Mr. Banon, Mr. McDowel, Mr. Egan, Mr. A. Walsh, Mr. W. A. Elliott, Prof. Benson, Prof. Hargrave, Dr. Shekleton, Mr. Rumley, Prof. Wm. H. Porter, Mr. Butcher, Mr. Fleming, Mr. Johns, Mr. J. T. Maguire, Mr. F. L'Estrange, Prof. Geoghegan, Mr. Tufnell, Mr. William Bevan, Mr. Wharton, Mr. G. H. Porter, Mr. William P. Geoghegan, Mr. Mayne, Mr. S. L. Bigger, Mr. J. Willett, Mr. B. W. Richardson, Mr. G. Ellis, Mr. S. L. Hardy, Mr. Joseph Burke, Mr. Pentland, Prof. Power, Prof. Hart, Mr. Jameson, Mr. Carte, Mr. McClintock, Mr. G. Elliott, Mr. Field, Mr. Campbell, Mr. Haffield, Mr. Leeson, Mr. Labatt, Mr. Faussett, Mr. Speedy, Mr. Croly, Mr. G. Davis, Mr. Plant, Mr. Osbrey, Mr. McGusty, Mr. Peebles, Mr. F. Byrne, Mr Lynch, Mr. Toler, Mr. Hamerton, Mr. R. Morrison, Mr. R. L. Nixon.

CORRESPONDENCE.

THANK-YE INSURANCE COMPANIES.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—The *Lancet* did much service to the profession in England by publishing the names of those insurance offices which refuse to pay medical men, but yet expect that they will give them valuable information. Knowing your zeal for the good of the profession, I would beg leave to suggest to you the propriety of your doing the same here. To commence, I will give you the names of two which have lately written for information, but declined giving any fee for it:—"The West of England Life and Fire," and "The Standard."—Your obedient servant, N.

March 17, 1852.

OVARIOTOMY.

By E. BENNETT, M.D., of Danbury, Connecticut, U.S.

I OPERATED, a short time since, for ovarian dropsy, on a Mrs. B—— of Redding. The patient was 52 years of age, was married, and had two children. She had usually enjoyed good health until about two years since, when she became somewhat indisposed, but not so much as to compel her to desist from her household duties. In the spring of the present year she consulted me, when I detected a tumour immediately above the pubis about half the size of the head of a new-born child. It was in the median line, grew rapidly, and soon fluctuated; she was tapped, I think, as early as March, by her attending physician, Dr. Gorham, twice within five or six weeks; the fluid was albuminous. I removed the tumour in June. It was adherent to the walls of the abdomen over a space about the size of the palm of the hand; no other adhesions. The wound appeared to do well. No appearance of inflammation within the abdomen; but she died from exhaustion on the fourth day. The operation was performed under the influence of chloroform. The sac was large, capable of containing a pailful, and was evidently multilocular; her age was against her; the operation was too long delayed; the fluid being albuminous, the restorative powers of the constitution were destroyed. I have not thought it necessary to go into the minutiæ of the case.—*Amer. Jr.*

TREATMENT OF UNUNITED FRACTURE OF THE PATELLA.

FRACTURES of the patella sometimes fail in becoming consolidated, but are united by ligamentous tissue, which is incompetent to sustain the necessary movements of the knee-joint. A case of this kind is recorded by M. Bonnet in the *Revue Medico-Chirurgicale*, in which he obtained bony union by a peculiar process, which, together with section of the triceps muscle, is thus narrated:—The subject of this case was a vigorous man, aged 44, who had been treated for fracture of the patella in the usual manner, without inducing consolidation. He therefore entered the Hotel Dieu of Lyons, under the care of M. Bonnet, who considered that some amelioration, at least, might be accomplished by section of the triceps; and after scarifying the ends of the bones, keeping them in contact by clamps, as suggested by M. Malgaigne. Accordingly, M. Bonnet commenced by subcutaneous section of the triceps, a few lines above the upper fragment. This allowed the descent of the fragment, which, together with the lower portion of the bone, was scarified by two other subcutaneous punctures, and the limb was then placed in appropriate splints, with the heel elevated. For the first few days there was some swelling of the joint, but the inflammation speedily subsided, and M. Bonnet proceeded to complete the operation by inserting small screws into each fragment, and causing these to be brought together, and retained in apposition by waxed thread. The screws are said to have remained forty days without producing any other unpleasant effects than some hydrarthrosis. The result was highly satisfactory, the fragments being brought nearly into apposition, and the uniting tissue being sufficiently resisting to allow of active use of the limb.—*Prov. Jour.*

MEDICAL CHARITIES BILL FUND.

Dr. Morrison begs to acknowledge the receipt of the following sums :—

M. W. HANLON, M.B.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

SCHOOL OF SURGERY.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Summer Courses of Lectures will Commence the Last Week in April, when Lectures on the following subjects will be delivered, in accordance with the regulation of the Council of the College:—Materia Medica, Medical Jurisprudence, Practical Chemistry, and Botany.

Just published, 8vo, pp. 96, price 2*s.* 6*d.*,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By Arthur Jacob, M.D., F R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5*s.*,

THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the Medical Press, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

Just published, in foolscap 8vo, price 5*s.*, cloth,

LIFE OF DR. JOHN REID,

Professor of Anatomy in the University of St. Andrew's.

By George Wilson, M.D.,
Author of the "Life of Cavendish."

Sutherland and Knox, Edinburgh. Simpkin, Marshall, and Co., London.

THE MEDICAL DIRECTORY FOR IRELAND, 1852,

Price 6*s.*, is now ready, containing the Name, Address, Qualifications, Appointments, and Literary Productions of every known qualified Practitioner in that Kingdom—Almanac—Universities—Colleges—Halls—Hospitals—Dispensaries—Medical and Scientific Societies—Obituary,—and a large amount of Miscellaneous Information relating to the Medical Profession.

London: John Churchill, Princes-street, Soho; and 4, Adam-street, Adelphi. Dublin: John Fannin and Co., 41, Grafton-street.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT

G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

Bleeding, Cupping, the Application of Leeches, &c.

G. O. and Co. continue to be Supplied with the Foreign Mineral Waters Fresh from their various Springs.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, Arthur Jacob, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Dr. JACOB in the chair.

CASE OF MALIGNANT TUMOUR—DISCUSSION ON THE VALUE OF THE MICROSCOPE.

By Dr. BANON.

DR. BANON exhibited a specimen of disease of the uterus, which, he said, would be regarded with some degree of interest, in connexion with the proceedings of the last meeting of the Society. It was yet in their recollection that on that occasion the subject of malignant disease was brought under their notice by Mr. Butcher, whose paper was illustrated by a variety of interesting cases; by Dr. Bellingham, who presented a very remarkable specimen of an encephaloid form of cancer; and by himself, in connexion with a cancerous growth of enormous extent which existed in a very young child, and was found in the cellular tissue behind the peritoneum, forming what was commonly called "a post-peritoneal tumour."

The case to which he then wished to direct attention, occurred during the past week, but as yet, not having had time for a careful examination, he had not been able to ascertain its exact nature with any degree of certainty. It was a firm resisting tumour. It was composed of a number of lobes connected together by loose cellular tissue, and when firm pressure was made upon it, an exudation of a creamy-looking fluid took place. The woman, who was the subject of the case, was taken into the hospital for phthisis, and it was a remarkable fact that there was no symptom whatever which was likely to call attention to the uterus.

The patient ultimately died of phthisis, and on making an examination of her body, this tumour was discovered between the muscular fibres of the fundus of the uterus; and it was a rather peculiar feature of the case that on the day preceding her death she was menstruating, and continued to menstruate up to the time of her death. She was about 35 years of age, had not been married, and had never borne any children. The cavity of the uterus was larger than would be expected in a virgin; a cyst was attached to one of the ovaries, containing a small quantity of fluid, and a hydatid hung from the same ovary.

Though he had not yet examined the tumour under the microscope, he was strongly inclined to believe that it was of a malignant nature.

Dr. JACOB said that on the last night of meeting, when Mr. Butcher brought forward his admirable communication, justice was scarcely done, by the discussion which then took place, to the important subject of malignant growths; but he was happy to say that an opportunity was then presented for any further remarks which members might wish to make, in connexion with malignant disease—the subject being one which at the present time was under general discussion in the medical world.

Dr. BEATTY said, that as far as a cursory examination of the tumour could enable him to judge, he could not agree with Dr. Banon that it was of a malignant character. It was not, in his opinion, the common fibrous tumour which they met with in the uterus; but it presented some of the characteristics of the fatty tumour which was found in that organ. He did not think it was encephaloid, and if he were to give it a name, he would say that it resembled a fibrous tumour more than any other with which he was acquainted.

Dr. BANON could not perceive anything like a fibrous arrangement in the tumour with the naked eye, nor any of the characteristics of cancer enumerated by the medical authorities; but on the whole, he was of opinion that it resembled a malignant growth. At the same time, he entertained the greatest respect for the opinion of Dr. Beatty, whose experience and opportunities, in reference to diseases of this character, were so much greater than his own.

Dr. H. KENNEDY remarked that on two or three occasions he had seen scrofula and malignant disease together in the abdomen. He thought the fact a remarkable one, though he was unable to say at what period either disease took its origin. Before sitting down, he would ask whether in cases of that kind, the microscope was more likely to

throw light on the real nature of the disease than the unaided eye. Though he had not seen the paper, he understood that an eminent microscopist of France had recently stated that the microscope would not go further, in detecting the nature of these cases, at a post-mortem examination, than the naked eye; and he had reason to believe that persons who were in the habit of using the naked eye in such cases, acquired a degree of skill scarcely, if at all, excelled by the professor of microscopy.

Dr. Banon observed that the microscope was considered to be useful because it enabled them to ascertain the existence of certain encephaloid cells which were always found in connexion with cancerous structures.

Dr. Jacob said that Dr. Kennedy had challenged the histologists to prove by the microscope whether a structure was or was not cancerous; if this was not answered many persons might draw an unfavourable conclusion as to the utility of the instrument in such cases.

Dr. Carte did not rise to defend the microscope, but simply to try and place it in its true position as *an additional* means of detecting malignant from non-malignant structures. A great deal had been said against the use of this instrument, but something also, he thought, might be said in its favour. If taken alone or in an isolated way, it would not perhaps prove of so much value as when taken along with other and concomitant circumstances, when the results were well known to be very satisfactory. What Dr. Kennedy had stated was in a great measure quite true; no doubt, as in former days, an experienced observer might distinguish malignant from non-malignant growths without the aid of the microscope; so likewise in the present day the practised eye will still without this instrument determine the character of each peculiar growth, and which the inexperienced eye could not do even with the aid of the microscope. He (Dr. C.) had paid some attention to the use of the instrument, and the result was, that he generally made his diagnosis upon the presence of certain peculiar nucleated cells mingled more or less with fibrous stroma; but both of these are greatly modified according to the species of the diseased structure under examination, and which are not present in growths of non-malignant character. He was quite convinced that the practice of decrying the microscope was in a great measure to be attributed to the great amount of patient labour which it involved, requiring, as it occasionally did, some three or four hours for the examination of a single specimen to arrive at anything like a satisfactory conclusion. It may be in the recollection of the Society that about a year ago he brought under their notice an enormous tumour springing from the forearm, which bore all the external appearances of fungus hæmatodes, but which in reality was a colloid growth. On that occasion it took him six or eight hours before he could distinguish a cell of any kind, and consequently he felt for the time disposed to withdraw his faith from the microscope: however, with the assistance of reagents, a proper adjustment of the light, and an additional stock of patience, he was enabled to discover them, the cause of failure being due to the extreme tenuity of the walls of the cells and the great amount of them, and their being congregated in such a way as to prevent the eye from defining them with accuracy. Gentlemen, he thought, should not be in too great a hurry to decry an instrument which was in its infancy, and it should be held in remembrance by them that another most valuable instrument—*the stethoscope*—when first introduced, was, if possible, more decried by some of the most eminent men of former days; but who would be without this valuable instrument now? It may therefore not be advisable to attempt, by the same species of opposition, to put down the microscope, which promised to be of equal utility in a different department of medical science.

Mr. Butcher observed that his experience with the microscope, which had extended over a very ample field of observation, led him fully to concur in the views laid down by Dr. Carte, which were also those laid down by all modern pathologists. Some of them throw a degree of doubt on the formation of the cell which was characteristic of cancer; and Dr. Bennett, whose researches on the subject were well known to them all, though he also laboured under some doubt in the matter, had laid down a few particulars which were, in his opinion, in all cases indicative of cancerous degeneration—namely, 1st, where encephaloid cells were found in a certain fibrous arrangement of structure; and 2nd, where the cell-wall was dissolved by the addition of acetic acid, and the nucleus became *more* distinct. In several instances he (Mr. B.) had tested the accuracy of these views, and very recently he brought before the Society numerous cases which bore him out in his statement. He knew that Dr. Lyons and many others in Dublin, who had applied themselves to that particular branch of study, could corroborate him fully in what he had advanced—namely, that it was possible to arrive at a certain conclusion as to the malignancy or non-malignancy of a particular structure. In saying so much, he thought he had said quite enough in reply to the question raised that evening by Dr. Kennedy; and for any further information he would refer such gentlemen as were sceptical on the subject, to the many able books which had lately been written upon the subject, in which the several writers had agreed in handing down the points he had mentioned as facts which had been ascertained beyond all doubt to be characteristic of malignant disease.

Dr. Stapleton said that all Mr. Butcher had stated might be perfectly true, but he would like to know whether the writers in question could particularise a cell in such a manner as would enable them, not taking into account the concomitant circumstances, to say that it was really and truly a cancerous cell. For his own part, having examined a variety of specimens with the microscope, he had not been able to satisfy himself that he had seen any single cell which he could say was a true cancerous cell. He agreed with Mr. Butcher that if they took the concomitant circumstances, they would be able to decide as to the malignancy or non-malignancy of a certain growth; but he would feel obliged to any of those gentlemen who, having devoted more time to the subject, were better informed respecting it than himself, if they would describe to him what they called the "cancerous cell," which was to be found in growths of a malignant character; and let him know whether he might expect to meet with it in carcinoma, in fungus hæmatodes, or in any other form of cancerous growth? Could they, in short, delineate any cell whose characteristics were so definite as to enable him, without the aid of the concomitant circumstances, to point out any particular form of disease?

Dr. Carte did not mean to convey that fungus hæmatodes and the other species of malignant disease were characterised by one form of cell. In his opinion the determination of each species depended upon the relative proportion and disposition of the cells with regard to the fibrous matter, and the amount and nature of the peculiar fluid contained in such growths. He wished it to be understood that the microscope was not to be taken up as a mere toy, but rather as an instrument to which a man must devote his mind and attention, otherwise the result may prove quite unsatisfactory, leading to disappointment.

Dr. Stapleton understood Dr. Carte and Mr. Butcher to say that if they took the concomitant circumstances into account, they might be led to conclude that it was a malignant growth; but that was not the answer he required. What he wanted to know was whether, taking fungus hæmatodes as the true type of cancerous disease, he was to believe that there was a particular cell in it, which might be easily pointed out to him—putting aside altogether, want of knowledge, want of light, or want of a perfect instrument—as indicative of malignant disease?

Mr. Butcher admitted that the question was one of great difficulty, and that it was considered to be so, not only in England and Scotland, but also on the Continent, where it first originated. Still he would persist in saying with Dr. Carte, that there was a particular cell, which it was not necessary to isolate; and also a particular juice expressed from cancerous or malignant growths which was

capable of yielding cells which no other fluid would be found to yield. That was a proof which he regarded as conclusive with respect to cancerous degeneration.

Dr. Jacob said they must not permit it to go abroad that any member of that Society was disposed to decry the microscope. Its powers had no doubt been questioned to some extent, and he was glad the question had undergone discussion, because the effect of that discussion would be to make the cancer-cell a test object for some time to come, until they could arrive at a clearer judgment. While they did full justice to the instrument, they should have its powers accurately determined and placed within their proper bounds.

Dr. Stapleton said that for his part he would be very sorry that he should be looked upon as an opponent of the microscope. In point of fact, he advocated its use, and it was for that reason that he had taken part in the discussion that evening.

Dr. Banon stated that he found he had committed a mistake in saying that no examination of the tumour had been made in the case which he had laid before the Society on that occasion. He had since ascertained that after it was left at the College of Surgeons, it was examined by Mr. Carte, who had succeeded in detecting in it some of the cells which were characteristic of cancerous disease. About eighteen months ago he submitted to Dr. Carte a tumour which he had removed from the breast of a woman, of which he (Dr. B.) said there was considerable doubt as to its malignant nature. Dr. Carte subsequently gave him a drawing which represented the appearance of the tumour under the microscope, stating that in his opinion it was a cancerous tumour, and that if watched, it would probably return, which prediction was ultimately verified, as the disease returned with greater malignancy than ever, and the woman died from its effects.

MEDICAL SOCIETY OF LONDON.

Dr. H. Jones read a paper

ON THE MORBID CONDITIONS OF THE KIDNEY GIVING RISE TO ALBUMINURIA.

The author commences by referring to the fact noticed, and dwelt upon by Mr. Bowman and others, that in consequence of the peculiar arrangement of the vascular system of the kidney, a more than ordinary pressure is exerted upon the capillaries of the Malpighian tufts, which, at the same time, being unsupported by fibre or solid tissue, are therefore peculiarly liable to rupture and hæmorrhagic effusion. These peculiarities will of course tell with increased effect if the organ becomes actively congested. These well-marked conditions of the kidney are noticed as existing in albuminuria. The first is the condition of engorgement, such as is seen in those who die in the early stages of acute anasarca, or in that of dropsy succeeding scarlatina. The organ is enlarged, dripping with blood in every part, its tissue not destroyed, but many of the tubes are seen under the microscope to contain coagula of exuded fibrine entangling blood globules, and more or less of epithelium. Under timely and appropriate treatment, the author believes that complete recovery from this affection may take place, and the kidney be restored to its original healthy state. He formed this opinion partly on the result of one examination, partly on the testimony of general experience with respect to the recoveries which take place in scarlatinal dropsy. The second form of diseased renal structure described, is that of the large, heavy, often mottled, and pale kidney. In this there is no hyperæmia, or rather the reverse state usually exists. The cut surface has not the appearance of healthy structure, and gives one the idea of some matter having been implanted among the natural constituents, so as to obscure them, and to produce a confined aspect. The tubes are found impacted with epithelial matter, but not by any means constantly obstructed or blocked up, although they are irregularly dilated. In some parts, though this is not the case in all instances, oily matter is deposited, and makes the tubes, where it exists, quite opaque. The evidence is, however, as clear as possible, that the morbid process is not of the nature of fatty degeneration. The Malpighian tufts are often obscured by effused matter, and the medullary tubes more or less filled up with oily, or granulous matter, washed down into them. The author believes that this state of disease may arise, either as a primary degeneration, without any preceding engorgement and hyperæmia, or that it may be the sequel of the first described condition. The third variety of morbid change is that so familiar to observation as the dwindled granular kidney. The organ is generally somewhat congested, the cortical secreting tissue remarkably atrophied, the capsule adherent to the surface, which presents the well-known granulations. In advanced cases there is found extreme destruction of the tubes of the cortical substance, their basement membrane is gone, their epithelium scattered about as mere *debris*, and their place occupied in many cases by an abundant cyst formation; the medullary tubes are filled up very often with more or less of granulous and oily matter. The Malpighian tufts are sometimes compressed, sometimes obscured by films of exuded matter, sometimes they seem tolerably healthy. There is no very decided evidence of the formation of new fibrous tissue, as in scirrhus of the liver, but the nutrix often seems to have lost somewhat of its natural homogeneous aspect, and to be infiltrated with a granulous stuff. The author coincides entirely with Mr. Simon's account of the origin of the cysts which are so numerously developed in many cases of granular kidney; he thinks the two following arguments conclusive as to the question whether they are formed solely from an alteration of the tubes, or as a secondary development out of their *debris*—1st, that, as Mr. Simon observed, they have a diameter sometimes less even than that of the tubes themselves; and 2nd, that they are not formed in nearly all the instances of kidneys which have apparently undergone precisely similar destructive change of their tubular structure. He believes, however, that cysts are formed by dilatation of the tubes, and perhaps of the Malpighian capsules. The author adopts Dr. Prout's view, that the nature of the morbid change in the two latter forms of renal disease, is not such as can with any propriety be considered as inflammation, sub-acute or chronic; he coincides entirely in the original idea of this celebrated physician, that the disease is truly a degeneration, a spoiling, and impairment of the whole organ, occurring quite independently of inflammation; but on which, inflammation or congestion may very easily, and does very commonly, at various times, supervene. This opinion seems to be strongly supported by the acknowledged causes of the disease, which are all of a debilitating nature, exhausting the organic life and vigour of the system. He further contends that the mere exudation of coagulable material into the tubes is insufficient to account for the atrophic change, since it might continue to be washed out by the urine, which does not depend on their being retained in the organ, but on their being no longer formed in consequence of the hyperæmia having subsided. In the treatment of acute anasarca, from whatever cause, cupping on the loin, bleeding if the strength allow, and tartar emetic, are pointed out as the means on which reliance may be placed. The action of the skin is to be promoted, and saline and other diuretics forborne, until the latter stage of the disease, when the author believes they may be employed with benefit. He compares their use at such times to that of squills or the balsams in the latter stages of a bronchitis. In the chronic form of disease, constituting "Morbus Brightii," the author remarks, that the degenerative nature of the affection should never be lost sight of, and that our chief endeavour should be, as long as any hope remains, to uphold, strengthen, and improve the constitution, by every tonic and corroborant means in our power. It is suggested also, whether, in consequence of the ascertained condition of the renal organs, their tubes containing unnatural, dense, accumulated epithelial matter, and when the Malpighian tufts being also overlaid by effused

fibrine, it might not be of advantage to administer the alkalies, and especially the liquor potassæ, somewhat in the same way as was done by Mr. Brandish, in the hope of inducing a healthier condition of the epithelial lining of the tubes. This seems the more reasonable, from the known influence of the alkalies upon albuminous matters, and the experience we have of their deobstruent powers.

Dr. THEOPHILUS THOMPSON and Mr. CHIPPENDALE having briefly addressed the meeting, the Society adjourned, after a few words from Dr. H. Jones.—*Lancet*.

THE DUBLIN STUDENTS' MEDICO-CHIRURGICAL SOCIETY.

Mr. JOHNSTON FERGUSON in the chair.

REPORT OF A CASE OF ACUTE GLANDERS IN MAN, WHICH TERMINATED FATALLY: WITH NOTES OF THE POST-MORTEM APPEARANCE OF THAT DISEASE AS IT OCCURS IN THE HORSE.

By Mr. ARTHUR H. TAYLOR,
Clinical Clerk to the City of Dublin Hospital.

THE case which I purpose bringing under the notice of the Society affords us a good example of acute glanders, or more correctly speaking, of the acute, supervening upon the chronic form of that terrible malady.

M. W——, ætat. 51, married, a hackney-carman, residing in the neighbourhood of Baggot-street, is of leucophlegmatic temperament. When admitted he was very weak and exhausted, consequently I did not disturb him by asking him any questions as to his previous history. I, however, examined his wife, who gave me the following history of the patient up to the time of his admission into hospital:—States that his health up to about three years since had been very good: about that time he met with a severe accident, having been thrown from the seat of his car whilst driving, by which he received a severe head injury, with some contusions on the back. For this he was admitted into the City of Dublin Hospital, from whence he was discharged cured in about three weeks, but since that time he has never enjoyed such good health as before he received the injury, as he frequently complained of headache, with pain in his back. Has been extremely temperate for many years, and lived well. She further states, that about one year and nine months since, one of his horses became ill, with what in a short time proved to be glanders. This horse died in about three months. A short time after another of his horses became affected; it also died in about the same time. He then got two others, these also took the disease, in consequence of having been put into the stable where the others had died. Although it had been most carefully cleansed, having been sprinkled with solution of chloride of lime, aired, and whitewashed, these animals went on gradually becoming worse, when he disposed of them. Shortly after, about ten months from the death of the first, he got another horse; this was the fifth, and is the one which he now has in his possession. This animal was also placed in the same stable as its predecessors, it first having been carefully cleaned out as before; however, in about two months it also exhibited symptoms of the disease. This was about *nine* months since. In this animal there was a profuse, viscid puriform discharge from the right nostril, with of late (what appears from her description to have been) an abscess about the commencement of the trachea.

Thus it would appear that for the last year and nine months, he has been almost constantly attending and endeavouring to cure these glandered horses, sometimes having two under treatment at the same time. His mode of treatment, which consisted principally in syringing their nostrils with water, and strong solutions of sulphate of copper, and in removing the purulent matter which was constantly accumulating and obstructing those passages, exposed him very much to the danger of infection or inoculation, and it would appear he was fully aware of this danger, and was particularly careful, always washing his hands after touching them. Whilst attending to the present animal in August last, he received a slight injury on his right shin; he fretted very much about this at the time, as he was afraid some of the matter had got on the denuded surface, although it was difficult to imagine how such an accident could occur; it, however, healed in a short time, but she states shortly after a little "rash" came out over the part whence the skin had been removed. This alarmed him very much at the time, but it quickly disappeared, and she thought he had completely forgotten it, when, towards the end of October last, he got a slight cough, with a quantity of thin viscid expectoration, the cough was very trifling, and the expectoration was more as if it were drawn into the mouth from the posterior nares, than as if it were coughed up. He also had a discharge of a similar nature from the nostrils, but particularly from the one of the right side. He now became very much depressed, and indeed he never completely recovered his wonted cheerfulness from the time he had injured his shin. He went on in this way till about two months ago, when he complained of pain in his back, but that, she says, he thought was caused by the fall; for as I have already stated, he often complained of similar pains long before he had been attending glandered horses. He now, however, became very much afraid of getting the disease, but did not discontinue attending the horse, as he was very fond of it. He would frequently sit for four or five hours in the stable with it. He often, about this time, made the remark to his wife, that he was "afraid he would get knocked up some day or other." His cough became something worse; his appetite, which of late had been slight, now became even more so; he often was so unwell as to be compelled to go to bed, complaining of headache, pains in his back, and weakness. He went on in this way, sometimes better, sometimes worse, until February 26th. Up to this time he had been under the care of a medical man in the neighbourhood, who said it was like influenza, and gave him various mixtures, &c. But as he had not improved, and his spirits becoming more depressed, his wife requested one of the medical gentlemen of the hospital to see him, which he accordingly did this day, when the patient presented the following appearances and symptoms: Pulse quick, weak, and small; he seemed labouring under *intense mental despondency*; said that he had been attending glandered horses, and that he was afraid, as I have already stated, that some of the discharge had got into a slight scratch on his shin; complains of an unpleasant sensation or tightness about the heart; hardly sleeps any in consequence of the great *mental* anxiety under which he suffers. Schneiderian membrane of right nostril highly vascular, injected, and congested, and rapidly pouring out a quantity of thin colourless viscid discharge. On the soft palate, in one part, there was some appearance of redness, which he said was a little tender. Ordered the following bolus every third hour:—

℞ Carb. ammoniæ, gr. v.
Camphoræ rasæ, gr. iii.
Theriacæ q.s. M.

He was also directed to have one grain of muriate of morphine at bedtime.

27th. Pulse improved; slept well, but does not feel better, but rather worse; slight effusion into both eyelids; eyes suffused; great lassitude, and feeling of impending danger; discharge increased.

Cont. omnia ut antea.
Injictr. enema purgans statim.

29th. Pulse quick and compressible; tongue dry and coated; is much worse; feels greatly depressed, and is confined to bed; complains of headache; upper lip somewhat swollen; nose swollen and inflamed looking; discharge altered, being now *thicker and more puriform* than on any of the previous visits; nearly complete loss of appetite. He was directed to continue all, and to have as much beef-tea or any other nourishment as he can take. He, however, continued gradually becoming worse until March 3rd; when visited this day, he was very much worse; nose and eyelids more swollen; despondency increased. CONT. omnia.

4th. Was this day admitted to the City of Dublin Hospital, under the care of Dr. Williams. When admitted he was extremely faint and weak; pulse slow and very feeble; tongue dry and brown; face pale and languid; eyes suffused; right eye considerably swollen; right side of nose much swollen and covered with a number of *large, well-formed, yellowish pustules*, resembling in appearance the pustule of confluent small-pox, wholly confined to the nose, and most numerous on the right side; discharge diminished in quantity, but *thicker and more opaque;* cough with *diminished expectoration.* Directed to have a separate ward, and no communication with the other patients.

5th. Pulse improved; sleepless night. Ordered beef-tea diet, with six ounces of wine, at intervals during the day, with two ounces at bedtime, containing one grain of muriate of morphine, and the following:—

℞ Carb. ammoniæ, ʒss.
Mur. morphii, gr. iss
Theriacæ q.s. M. In bol. sex. Capt. i. ter die.

6th. Pulse 102, very weak; *cough slight, with thick yellowish viscid expectoration;* pustules extended, but still confined to the nose, which is very much swollen; conjunctiva of internal angle of right eye somewhat inflamed; *œdematous swelling of both eyelids;* slept well, but does not feel refreshed, and seems worse. Ordered ten ounces of wine during the day, with more if necessary, and a grain of muriate of morphine as before.

℞ Spt. ammon. aromat. ʒss.
Liq. Hoffman, ʒii.
Mist. camphoræ, ʒvii. M.
Capt. cochl. i. ampl. quaque hora.
℞ Carb. ammoniæ, gr. xvi.
Mur. morphii, gr. i. M.
Ft. pil. viii. Capt. i. secunda quaque hora.

7th. Pulse 102, weak; tongue dry and brown; erysipelatous inflammation extended over the centre of the forehead; one large badly formed pustule over the nose on the forehead; both eyes very much swollen; inner angle of right eye much inflamed, and presenting an appearance as if a pustule were about to form there; *complains of pain in left shoulder and hip*, and in various parts of the body; slept heavily during the night; nose greatly increased in size, and the parts where the pustules first made their appearance are now dried up and covered with a *dark, somewhat purplish incrustation.* Cont. omnia.

8th. Pulse 98, fuller; there are now eight *semi-gangrenous phlyctenecæ, or badly-formed pustules*, on the forehead, seven new ones having made their appearance since yesterday; the pustules did not appear in this way on the nose, and it would seem that there is now a decided change in their mode of appearance; the spots are now preceded by an erysipelatous inflammation of the part about to be affected; both sides of the nose are now equally engaged; but for the extension of the spots to the forehead he is not perceptibly worse; cough very distressing in consequence of the thickness and viscidity of the expectoration. Cont. omnia.

9th. Pulse 114; tongue not so dry, but marked with a broad dark line down its centre; slept well; increased number of spots on the forehead, presenting a very gangrenous appearance, being of a dark purple colour; the line of tumefaction on the forehead is very well marked, but does not show any tendency to affect one side more than another, the tendency to spread being more vertical than otherwise; no discharge from the anterior nares for the last two days, the discharge, if any, being taken into the pharynx by the posterior openings, as the nostrils are now completely closed by the dried matter and quantity of incrustation about the nose with which it is now completely covered; no abnormal appearance in any other part of the body, discoloration or otherwise; pains in hips and shoulder nearly completely gone, and this without any external appearance of any kind; both eyes closed up with œdematous swelling of the lids; has taken twenty-eight ounces of wine during the last twenty-four hours; also some porter and *yeast;* the latter was recommended as an antiseptic ferment; does not appear worse, but for the extension of the spots; bowels confined.

Cont. omnia
Habeat olei ricini, ʒvi. statim.

10th. Decubitus this morning on mouth and nose; and it appears that from the increased viscidity and consequent difficulty of discharging the expectorated matter from the mouth, he has of late found that position the easiest; increased discoloration of forehead, and more to the right side; increased number of spots; did not sleep so well last night, and when sleeping was very restless, with laboured respiration; the phlyctenecæ on the parts corresponding to their first appearance on the forehead have become broken, and are now discharging a small quantity of sanious matter; seems much worse to day; pulse 132, weak, and very easily compressed; has been getting wine as before, with the addition of jelly. I saw him about an hour after the last note, and on endeavouring to get him to swallow some wine he could not; he was then lying on his back perfectly inert, head thrown back, and mouth open; shortly after a drawing was made of him in this state, and in about an hour he died. There was no post-mortem.

The horse from which the deceased contracted the malady was destroyed, and Mr. Hugh Ferguson, veterinary surgeon, who examined the animal, both before and after death, stated that it had chronic glanders; and he kindly furnished me with notes of the post-mortem appearances in the animal, which I shall now read, with your permission, and think they will prove interesting, as it is but reasonable to suppose that when the disease in the horse and man are alike, there must exist a certain amount of similarity in the pathological appearances in both.

Post-mortem examination of the horse.—The mucous membrane of the nasal cavities of a yellowish red colour, much thickened, having numerous ulcerations, with indurated and reddish margins, many of them running one into the other by lateral extension. These ulcers were covered in some parts with a thick cheesy matter, which, on the ulcers of older standing, was mixed with some of a thinner and more fœtid character. The ulcerations in some places extended not alone entirely through the thickness of the mucous membrane, but also affected the cartilaginous septum to a considerable depth. Knotted cords in the mucous membrane, irregular in their direction, extended towards the guttural openings. All the sinuses of the head, as well as those of the turbinated bones, contained a yellowish glairy mucus, of ropy consistence, streaked with blood. There were ulcerations in the larynx. In the substance of the mucous membrane of the air-passages of the head, might be detected several white lenticular bodies, which by some might be denominated tubercular, easily crushed, surrounded by red circles, which is the preliminary state to the ulcerative stage already described. The entire tissue of the lungs contained, or was studded with tubercular-like depôts, few larger than the size of a small pea, formed of albumino-fibrous matter, easily crushed between the fingers, having their centres of a dirty-whitish colour; the tissue by which they were surrounded being of a bright red colour, and very friable. The superficial lymphatics of the lungs were easily visible, being abnormally large and unusually numerous. Those glands through which lymphatics passed from the different seats of ulceration, such as the submaxillary, subparotidean, pectoral, bronchial, and inguinal ganglions, were much enlarged, and were surrounded with inflammatory infiltration into the cellular tissue. There was a general tendency to œdema.

THE MEDICAL PROFESSION IN FRANCE.—The *Union Médicale* states that in 1812 there were 537 medical men practising in Paris, whilst in 1851 there were 1352, being an augmentation of 815 in forty years. The population of Paris in 1812 was 547,756 inhabitants, or 1018 persons for each medical man; at present it is 900,000—666 for each medical practitioner.

ORIGINAL COMMUNICATIONS.

OVERDOSE OF CROTON OIL.

By R. Crothers, M.D., of Moy.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I enclose a report of a case in which an overdose of croton oil was taken by mistake. Should you think it worthy of a place in the columns of your valuable journal, you will oblige yours very truly, R. Crothers, M.D.

Moy, March 25, 1852.

On October 25, 1850, I was sent for about six p.m. to visit a lady, labouring under phthisis, who had just swallowed a teaspoonful of croton oil, having mistaken it for a mixture of syr. ferri iod. From taking it quickly, the taste was not observed until it was completely down. She immediately felt burning pain in the mouth, pharynx, œsophagus, and stomach. When I saw her, about fifteen minutes after, she was in a state of great alarm; she had drank freely of warm water, and had vomited. I gave an emetic of zinc. sulph., which acted immediately; the ejected matters having a strong smell of croton oil, and followed this up by draughts of salad oil and milk, which, although vomited, relieved the pain in the mouth and throat; but that in the stomach continuing, I gave magnesia, and afterwards soda in milk, in order to combine with any oil which might still remain attached to the mucous membrane. She felt great relief from this, and soon after threw off a little, but without any smell of the oil. She was very much exhausted.

Half-past seven. The bowels were now very freely opened, and she vomited a dark-coloured soapy matter, with almost complete relief from pain. This was succeeded by great weakness; the pulse had fallen from about 136 to 90. She soon became almost collapsed; the skin felt cool; the forehead cold; with faintness. After getting some ether and tr. opii in aq. cinnam. she revived a little; but attacks of this kind recurred at intervals of half an hour, or even oftener, until about two a.m., so that I was obliged to remain by her side and endeavour to keep up the action of the heart; in fact, to combat the tendency to death by the constant use of ether, wine, external heat, &c. She then had some rest, but about four a.m. griping, with slight purging, commenced, and severe burning pain in the rectum. On visiting at seven a.m., I found reaction set in; skin warm; tongue clean, red; no tenderness of epigastrium or bowels; pulse still diminished in frequency, from 80 to 90; before this it was usually about 120. Still complains of severe pain in rectum and great exhaustion. Ordered fomentations and starch enema, c. tinct. opii, beef-tea, and mucilage (had been using the latter), and to continue the stimulants carefully.

Ten a.m. Could not get the enema on account of the soreness of the part.

℞ Opii gr. ii., statim, et gr. i. omni secunda hora in pil.

The second dose gave so much relief, that it did not require to be repeated. Next day she was as well as usual, but weak and sore from the vomiting, and no appearance of gastric irritation, except redness and soreness of the tongue. On the third she required a gentle aperient. In about a fortnight after, I was applied to respecting a return of pain in the rectum; it was relieved by a suppository with opium, and I believe gave no further trouble. The pulmonary symptoms were rather relieved for a time, and the pulse kept low for several weeks after.

It is to be feared that the result in this case would have been very different only that she had dined about two hours before, and the stomach being partially filled with food, prevented the oil from acting so quickly and producing the powerful purgative effect which it otherwise would have done. The vomiting was also less exhausting than in an empty state of the stomach, and did not require to be kept up so long, a matter of great importance, in a patient who was already suffering from extensive disease in the lungs. She died in August last, and never suffered from diarrhœa even in the most advanced stage of her disease. The quantity of oil swallowed was fully one drachm.

DUBLIN MEDICAL PRESS

LONDON HOSPITAL REPORTS.

CHARING-CROSS.

Amputation at the Shoulder-joint.

By Mr. Hancock.

Ann V——, aged 29, of fair complexion, blue and somewhat wild-looking eyes, was admitted April 10, 1851. She is evidently of a highly nervous and excitable temperament; has generally attended to household duties, without any fixed occupation, and seems to be affected with the peculiar hysterical tendency of exciting as much as possible the attention and sympathy of those with whom she comes in contact. The left arm has been amputated at about the middle point between the head of the humerus and the condyles, and the stump is constantly and convulsively moving, principally in a direction from above downwards. The pectoral muscles, the trapezius, the scaleni, and the platysma myoides, are also strongly agitated, and the parts are never at rest except when the patient is asleep.

She states that she was seized, about sixteen years ago, with severe pain and inflammation of the elbow-joint (without having met with any injury), and soon after a rather serious illness, probably continued or other fever. For these symptoms she was actively treated; but becoming worse, she repaired to town, and placed herself under the care of the late Mr. Morgan, at Guy's Hospital. Here the usual means employed for diseases of joints were carefully used, but to no purpose; and Mr. Morgan was at last obliged to take off the arm—a period of five years having elapsed between the first onset of the articular disease and this amputation. The patient returned to the country before the stump was completely cicatrized; the healing process was completed in about two months, and a firm cicatrix formed.

At the expiration of three months after the operation, and one after the entire closure of the wound, the stump began to move convulsively, most of the muscles of the shoulder and neck connected with the arm soon partaking of the spasmodic twitchings. This had been preceded for several days by very intense pain in the extremity of the stump. Soon afterwards, a collection of matter occurred in the part, and she was then several times seen by the late Mr. Aston Key at St. Alban's, who recommended her to return to Guy's Hospital. She now stayed in that institution for several months, during which blisters, setons, issues, ointments of various kinds, and general treatment, were tried with great perseverance, but without any relief to the convulsive action or to the pain. Among the means employed, was the tying down of the stump; but when the latter was well secured, and the movements completely prevented, the *whole body* used to be thrown into convulsions. The pain would sometimes radiate from the stump to the neck, back of the head, and down the spine, and convulsions occasionally were noticed in the left thigh, leg, and great toe. Even the right shoulder shook now and then violently, and became exquisitely painful. She often woke suddenly, and found both the left leg and the stump in violent convulsions, but the movements used mostly to cease during sleep. The patient, however, stated that she had often been told that the stump, even when she was sound asleep, would start occasionally. It was likewise noticed that, at the height of the convulsive action the skin and cellular tissue of the cicatrix became violently retracted.

Some time after leaving Guy's the patient was admitted into St. George's Hospital, where the series of remedies available and sometimes efficacious in such cases, were successively tried, but as none gave any relief, amputation at the shoulder-joint was mentioned, and agreed upon, two years having elapsed since the removal of the arm. But at this time a new feature arose in the patient's case; severe epileptic fits set in, which occurred more or less frequently for the space of two years after she had left St. George's.

We now find that the girl fell into the hands of a mesmerist, and she states that the convulsive action generally

stopped during the artificial sleep But it is difficult to put any faith in the circumstances connected with this period of the patient's history, as everything coming from such quarters must be received with extreme caution. There can be no doubt, however, that the girl must have been made much worse by the mesmeric juggleries, and that her present nervous, hysterical, and excitable condition is principally owing to the constant irritation offered to her nervous system during seven years' mesmeric treatment. After this, the patient suffered so much pain and inconvenience, that she applied for admission at St. Bartholomew's Hospital, where she stayed about nine months. The best-directed means were here again perfectly useless; the amputation at the shoulder-joint was proposed, but she seems to have been at that time unwilling to submit to this last resource. At St. Thomas's Hospital, whither the patient next repaired, Mr Green and Mr. Travers were of opinion that there was no chance of any relief but by removal at the joint. Some incisions were here made into the stump, but she left without consenting to the operation proposed.

Frequent blisters were subsequently applied to the part, as well as to the spine; galvanism was tried, but all to no purpose. The violence of the fits would sometimes abate considerably, and then she improved in health. She has always exhibited signs of indolence, and within the twelvemonth which preceded her admission into Charing-cross Hospital she gained much flesh.

The patient has amused herself in casting up the number of some of the remedies which were used in the different institutions where she was admitted, and finds that the stump was lanced twenty-five times, that she had 495 leeches, ninety-six blisters, &c. It should be particularly noticed that during all these years, the catamenia (which had begun at eleven) were always very regular.

Mr. Hancock endeavoured at first to give tone to the system, and to overcome the hysterical and nervous state of the patient. For this purpose, the most approved means, as quinine, steel, zinc, morphia, &c., were used for a considerable period, but without any very tangible effect. It was clear, after several months had elapsed, that a more direct interference would be required to subdue the convulsive action of the stump. There could be hardly any doubt but that the bulbs of the nerves were much enlarged, and that their great size would ever be in the way of a cure; Mr. Hancock therefore resolved, before having recourse to the complete removal of the stump, to dissect out the bulbous extremities of the nerves.

On the 22nd of August, 1851, whilst the patient was under the influence of chloroform, Mr. Hancock made a longitudinal incision, from the shoulder downwards along the anterior aspect of the stump. When the parts were fairly laid open, a bulbous mass, about the size of the last phalanx of the thumb, came into view. This was carefully freed from the surrounding parts down to the bone, and removed. During the operation the brachial artery was divided, and immediately tied; the lips of the wound were brought together, and when the stump was placed upon the pillow it was observed that the spasmodic movements had entirely ceased. This circumstance was extremely satisfactory, and confirmed the belief that the presence of the nervous bulbs had been mainly instrumental in the persistence of the symptoms through so many years.

This favourable state of things lasted about one month; the stump lay perfectly still, and hopes were entertained that this very obstinate affection was at last conquered: but the patient, having been seized by a fit of impatience, about four weeks after the last-mentioned operation, the stump began again to be convulsed, and matters soon became as bad as ever. It was now evident that nothing short of amputation at the shoulder-joint would be of any avail. Mr. Hancock therefore proposed the operation to the girl, who readily consented. On the 12th of November, 1851, the patient having been narcotized with chloroform, Mr. Hancock performed amputation at the joint, making a good flap of the deltoid muscle. It was noticed that the stump, when severed from the body and placed on the table, continued to be convulsively agitated for several minutes. No pathological appearance of importance was revealed by the examination of the stump, except that the nervous trunks were closely adherent to the bone.

The chloroform affected the patient to a very great degree for about twenty-four hours after the operation, the hysterical diathesis having a large share in the somewhat alarming symptoms which were observed. This doubtful state did not, however, last long; the patient progressed very favourably for several weeks, and it might now be fairly surmised that all the pain and inconvenience which had been undergone for so many years were arrested: but hardly had the cicatrix formed, about two months after the operation, when the muscular fibres forming the deltoid, those of the trapezius, the scaleni, a portion of the great pectoral, and even the platysma myoides, were again thrown into strong convulsive action. The movements were just as continuous and spasmodic as they had been in the stump. When the girl was not observed, the jerking was much less rapid than when she was either angry or excited. Some suspicion had previously existed, and was now made somewhat strong, that the movements were, perhaps, not completely involuntary. Mr. Hancock thought it now prudent to allow the girl to breathe the country air; she was therefore discharged, February 15, 1852, about ten months after her admission.

This is certainly one of the worst cases of the kind which have as yet been put upon record, with the only exception that Mr. Hancock's patient had no aneurismal pulsations accompanying the convulsive action. This case fully confirms the very generally received opinion that neuralgia and convulsive movement of stumps, depending on a bulbous state of the extremity of the divided nerves, are hardly amenable to treatment, and that even the very severest measures, such as a complete removal of the stump, are found inefficacious. That the hysterical diathesis so unmistakable in Mr. Hancock's patient must have had a very large share in the production of the symptoms, cannot for a moment be doubted; but it is clear, on the other hand, that the extremities of the nerves were more bulbous than is the case in the generality of stumps, and that there was a material and tangible cause for the symptoms besides the highly nervous and hysterical temperament. Had the patient never been affected with the disease of the elbow-joint, which led to the first amputation, it is very likely that the hysterical diathesis, which exercised its full force on the stump, would have manifested itself in one of the numerous ways belonging to hysteria.

We need but refer our readers to the paper of Mr. Langstaff, in the sixteenth volume of the Medico-Chirurgical Transactions, to show that the soundness of a stump depends very much on the manner in which the soft parts cicatrize, and that very severe symptoms are apt to ensue when the bulbs of the nerves, which form almost in every stump, are increased to such an extent as to assume a neuromatous character. As to the actual nature of the enlargement, a subject to which we alluded above, Mr. Langstaff says:—"I think it right to mention that on cutting through these bulbous extremities of the nerves, there are no signs of enlargement of their natural structure, the thickening appearing to have been occasioned wholly by the deposition of lymph, the effect of inflammation in the cellular tissue covering the neurilemma."

Mr. Langstaff mentions, in the same paper, the case of a girl, aged 20, whose forearm had been taken off, and who, like Mr. Hancock's patient, suffered from pain and convulsive action in the stump, with the addition of aneurismal pulsation. Every kind of means was tried at several hospitals without any favourable results; at last Mr. Langstaff took off the arm above the elbow-joint; and in describing the operation, he says:—"I drew out each nerve, to the extent of half an inch, from the surface of the stump, with a tenaculum, and cut through them to prevent their interrupting the progress of cicatrization, which I had done in other instances with success; and I

was astonished that the division did not occasion greater pain than was complained of by the patient." "This patient was relieved of all the painful sensations she had so long been distressed with; she had no recurrence of hysteria (which affection had been induced by the convulsions of the arm); her health improved; a good stump was effected; and she is now (1830) able to obtain her livelihood." We have some reason to suspect that this same patient had some time after the publication of the paper, a relapse; she then came under the care of Mr. Tyrrel, who performed amputation a little higher up, without effecting a cure. Mr. Bransby Cooper lastly removed the stump at the joint, and at this moment the soft parts about the shoulder are as convulsively agitated with this woman, as is the case in Mr. Hancock's patient.

ST. BARTHOLOMEW'S.

Death by Chloroform.

By Mr. Lloyd.

We regret to apprise our readers that the use of chloroform has proved fatal in this case. It will be clearly shown by the subjoined facts that no blame whatever can attach to any one concerned, the more so as the patient had, on a previous occasion, inhaled chloroform during a considerable time without any ill effects. We refrain from any comments, as we shall have occasion to return to the case when the post-mortem examination shall have been made.

Thomas Hayward, a rather spare and weakly man, ætat. 23, was admitted on Thursday, the 29th of January, 1852, under the care of Mr. Lloyd.

The patient applied to the hospital for an aneurism by anastomosis occupying the whole of the right ear, and also to a considerable extent the soft parts in front and behind that organ. On and behind the ear, the vascular growth was elevated so as to form a large tumour. The integuments of the ear, as well as the diseased mass, were of a deep purple colour. In every part there was strong pulsation, as well as a loud aneurismal murmur; the temperature, however, was much the same as that of the surrounding parts. Projecting from the meatus there was a polypus or large fungus, whence issued a copious purulent discharge, which was often tinged with blood. Pain in the head was complained of, but no unpleasant sensations had been felt in the tumour itself.

The disease had existed since the patient was four years of age; various remedial means had been employed at different times, but without benefit. The patient had been treated at some of the London hospitals, where setons were introduced into different parts of the tumour, and portions of it enclosed with silver wires, which were now and then twisted so as to tighten them; but these measures were of no avail, and at length the patient was discharged as incurable.

Mr. Lloyd, not deeming the cure hopeless, and having consulted with his colleagues, determined to attempt the obliteration of the tumour—first, by deligation of the principal arterial branches in direct communication with the diseased mass, and afterwards by pressure applied to different parts in succession. With this view, on the 14th of February, 1852, the patient was placed under the influence of chloroform, and with the assistance of Messrs. Wormald and Paget, Mr. Lloyd placed a ligature around the temporal artery, just as it passes over the zygoma; other ligatures were applied in such situations as it was considered would tend most to cut off the supply of blood from the part affected, and pressure afterwards used before and behind the ear. The operation lasted, as was expected, for a long time, and the patient was kept under the influence of chloroform for *half an hour or more*. From the effect of the anæsthetic agent he recovered quickly, and when visited half an hour afterwards, he was found lying comfortably in his bed, and on being asked how he was, he answered, "Very well," and smilingly added that he was very thankful the operation had been performed, and hoped it could soon be repeated.

After this everything went on favourably: the tumour became much diminished in size, and the pulsation much lessened. But on further examination, a large artery was found beating very strongly, between the mastoid process and the ramus of the jaw, pressure on which part completely arrested the pulsation throughout the diseased growth. On this vessel, therefore, Mr. Lloyd determined to place a ligature, and appointed the 17th of March for the purpose.

The patient was taken into the theatre of the hospital, placed on the operating-table, and chloroform administered as on the former occasion. The anæsthetic fluid now used was from the same bottle as had been employed before, and the apparatus was also the same as usual. The chloroform was administered by one of Mr. Lloyd's dressers, who well understood, and had long had experience in its use. A gentleman of great experience, who has been a long time at the hospital, and two years house-surgeon, was watching the patient, and marking the state of the pulse. Other gentlemen were also assisting.

In from five to ten minutes the usual effect was produced, the patient having previously struggled much. The operation was then commenced, but no sooner had Mr. Lloyd cut through the skin, than it was stated that the pulse had suddenly stopped. The chloroform was at once removed, but in a few seconds the patient had ceased to breathe, and no pulsation could be felt in any of the arteries, or at the heart. Artificial respiration as well as percussion and compression of the different parts of the body, were immediately employed, with energy; and after continuing the means for a short time, the circulation was observed to be returning, and the act of respiration was several times performed. The state of inanimation, however, speedily returned; but by the employment of the same means as before, with the use also of galvanism, the circulation and respiration were again restored. But the patient fell quickly into the same state as at first, and was again brought round by the same means. In a few moments, the patient relapsed for the third time, when one of Mr. Lloyd's colleagues, coming into the theatre, recommended that the external jugular vein, which on the right side was turgid, should be opened, that tracheotomy should be performed, and the lungs inflated. These means were accordingly had recourse to.

The patient was besides placed in a warm bath at the temperature of 104 deg., artificial respiration being kept up all the time, and friction employed. All, however, was of no avail, and it soon became evident that life was irrecoverably gone.

The resuscitating measures had been continued for more than an hour. Ammonia had been applied to the nostrils, but no attempt was made to introduce any stimuli into the stomach, as Mr. Lloyd feared any liquid placed in the mouth might pass into the larynx, and occasion instant suffocation.

Rupture of the Bladder.

The second case of rupture of the bladder which has of late come under our observation, refers to a patient who died very soon after the accident. The details are from the notes of Mr. Stretton, Mr. Lloyd's house surgeon.

The patient, a young man, aged 25, was admitted Feb. 25, 1852, under the care of Mr. Lloyd. When brought into the hospital, he presented a dull anxious aspect; skin cold; tongue foul; fœtid breath; sordes on the teeth; and constant sickness; pulse 132, very feeble. The patient stated that he had neither passed urine nor fæces for the last dwo days, though he had felt a great desire to do so. The abdomen was full, tense, and tympanitic, tender, but tolerant of moderate pressure; the knees drawn up, and the respiration chiefly thoracic.

The man gave the following details as to the cause of the symptoms:—Two days before admission he was out with some friends, and became intoxicated. Having left the public house to proceed home, he playfully caught his friend round the waist, and fell backward with the man on his lap. The patient immediately felt great pain about the

abdomen, and was unable to get up; a desire to pass water was also felt, as he had not micturated for some hours. He was carried home, put to bed, and attended by a surgeon, till his admission into hospital.

Mr. Lloyd ordered ether, ammonia, and laudanum, in camphor mixture; a poultice was placed on the abdomen, and brandy given at intervals. A catheter was passed, and eight ounces of urine, mixed with blood, drawn off; the bowels were also relieved, the evacuations being plentiful, dark-coloured, and slimy. The patient had great desire to pass urine whilst at stool, and thought that he had evacuated a little. On the next day he was no better; the tension of the abdomen and the pain had increased; he had had a restless night, and was altogether in a feebler state than when he was admitted. The sickness had, however, been stayed. The same medicines were continued, and Mr. Lloyd ordered, besides, small doses of mercury with chalk and Dover's powder every fourth hour. On using the catheter again, an ounce and a half of somewhat clearer urine was drawn off. But during this day the patient became gradually worse, and died late in the night, three days after the accident.

Autopsy fourteen hours after death.—No external marks of injury. On opening the abdomen, a quantity of sanious fluid, similar to that drawn off by the catheter, escaped. The great omentum was of a grayish colour, and firmly adherent to the peritoneum, lining the abdominal parietes and the fundus of the bladder. The intestines were glued together by recent lymph, which latter was easily broken down. A catheter, introduced into the urethra, passed into the cavity of the abdomen through an aperture on the left side of the fundus of the bladder, an inch in extent, and surrounded by coagulated blood. The viscus itself was much contracted, and could have held only an ounce of urine; some clots of blood were lying at the orifice of the urethra. About three pints of fluid were contained in the abdominal cavity; the portion which was collected in the pelvis was thicker, and contained coagulated blood, with soft lymph, apparently passing into pus. The rest of the viscera were healthy.

Though rupture of the bladder had been diagnosed in this case, there existed, however, a circumstance well calculated to deceive—viz., the withdrawal of eight ounces of urine from the viscus, or rather from the abdomen, for the catheter must have passed through the rent, and given exit to a portion of the urinous fluid, which was constantly escaping into the abdominal cavity. It will thus be seen that the evacuation of urine is not a sure sign of the integrity of the bladder.

KING'S COLLEGE.

Fracture of the Pelvis, Bladder, and Urethra; Death.

By Mr. FERGUSSON.

William P.——, a carman, aged 30, was brought into the hospital, December 24, 1851, having been run over two hours previously. It appears that while driving his cart through a narrow road, the patient found himself wedged between the wall and the vehicle, the horses having taken fright. The poor man had not time to rescue himself, but was knocked down, the wheel (the tire of which was six inches wide) passing between his legs, along the perineum, to the upper part of the right thigh, and by a sudden turn crossing over the abdomen. At the time of the accident, the bladder seems to have been nearly empty, as the patient had passed urine an hour before.

On his admission, he was very low, and complained of great pain over the region of the bladder, and in the loins, especially on the left side, the course of the wheel being distinctly marked by strong ecchymosis. The patient was immediately placed into a warm bath; and as he had not passed any urine since the accident, an attempt was made to introduce the catheter. The urethra was found much lacerated, and the catheter seemed to deviate from the straight course just before it arrived at the triangular ligament. With the finger passed into the rectum, the point of the instrument could be felt gliding between the gut and the bladder. Mr. Davis, the house-surgeon, finding his efforts fruitless, sent for Mr. Fergusson, at eleven p.m.

After having carefully examined the patient, Mr. Fergusson endeavoured for a short time to introduce the instrument, but without success. He gave it at the same time as his opinion, that there was but little, if any, urine in the bladder, and that the right ramus of the ischium was broken at its junction with the pubis. Ordered fomentations.

On the next day, there was not much change, and the patient did not seem to suffer much pain, except over the immediate vicinity of the bladder, which viscus did not appear to be distended; the tongue was moist, the pulse quick and feeble. Calomel, eight grains; opium, one grain,—to be taken at once. Another attempt was made to pass the instrument, but without success.

On the third day, the patient was found to have had a very bad night; he complained of severe pain over the bladder, and felt a great inclination to pass urine. It was thought that he might perhaps succeed in the warm bath, but he obtained no relief from it; nor were further attempts with the instrument successful. The abdomen now became tympanitic, but the pain remained located in the region of the bladder.

In the afternoon, as the patient was in much pain, Mr. Fergusson was again sent for, and the catheter tried, but without success; and Mr. Fergusson stated that the bladder was not distended, for he had found that on passing his finger into the rectum, he could feel no fulness about the bladder, the latter seeming free and capacious. Extravasation of urine was now suspected. Two incisions were made on the abdomen, and another in the left groin; but no urinous fluid escaped. The man continued in this state until about half-past two a.m. on the fifth day, when the pain became excessive and a sudden change took place. The nurse called up the house-surgeon; but before the latter reached the ward, the patient was dead.

The post-mortem examination revealed the following lesions:—The intestines were slightly, if at all, inflamed, but the true pelvis was filled with urine, so that when the viscera were pressed downwards, the fluid welled up considerably. When the opaque straw-coloured liquid had been taken out, no marks of peritonitis came into view. The bladder was now carefully examined. It was quite empty and collapsed, and on its posterior portion a ragged opening was observed, which might have admitted the index finger. The symphysis pubis was separated for the space of about one inch, and the ramus of the pubis fractured at its junction with that of the ischium. There was likewise a fracture of the ilium running into the acetabulum, and the sacrum was broken and separated from the bone. The urethra had suffered an extensive laceration in front of the membranous portion; from this latter fact it was now clear that the instrument, during the attempts at catheterism, had passed into the perineum.—*Lancet.*

HYDROPHOBIA TREATED BY CHLOROFORM.

J. GRAHAM, an intelligent healthy boy, aged three years and three months, was bitten on the 29th of January last by a dog, supposed to be rabid; at the time the accident happened, the child was playing with a companion in the road, in front of its own home; the dog flew at them, bit them both severely, and worried them. Upon examination of the little patient, it was ascertained that the apex of the nose was nearly detached; that there were three severe and extensive wounds on the side of the face, situated one beneath the other, one of which extended completely through the cheek into the mouth; that there was a deep wound beneath the right ear, laying bare and lacerating the masseter muscle; that the tragus of the same ear was also injured, and there was a deep punctured wound of the back of the right hand, besides some other abrasions of less moment. The extent of the injuries on the side of the head was such, that it was deemed impracticable to resort to excision, or the application of any cauterizing substance, as by so doing, the greater part of the side of the

face must have been removed; long-continued ablution, kept up for two or three hours, was therefore alone depended on; the lips of the wounds were brought together with strapping, and ordinary dressings applied, about five hours after the injuries had been inflicted; the same treatment was also adopted for the wound on the hand. The sores progressed well and rapidly, and the patient was discharged on the 11th of February, with all of them nearly healed. On the afternoon of Friday, February 20th, the twenty-second day after the receipt of the injury, his mother first remarked that he did not appear in as good health as usual, his appetite was diminished, he became exceedingly restless, and was frequently observed to draw a deep sobbing breath; he spoke repeatedly of the dog which had bitten him, apparently with great perturbation; he slept badly that night, and next morning became more fidgetty, feverish, and anxious looking. His bowels being rather confined, and his tongue furred, his mother gave him some infusion of senna, which she had some difficulty in getting him to swallow. During a great part of the day he suffered from vomiting, recurring hourly. Saturday night his rest was even more disturbed than it had been the night previously, and on Sunday he gradually grew worse and worse. His mother gave him a purgative powder which she had obtained from a chemist, after this his bowels were freely opened, and they subsequently continued regular. Towards the evening the restlessness increased, he became very excitable and nervous, and remained awake, in the same condition, during the whole night. The symptoms now began to be more pronounced, the slightest movement annoyed him, and produced a sort of convulsion; he frequently started, as though frightened, and clung to those around him, hiding his head with manifest alarm. On Monday morning he was attacked with a more severe convulsion than he had had previously, and his mother reports that he attempted to bite those around him; this first led her to fear the real nature of the malady, and Mr. Page was sent for. He found that the child had the greatest difficulty in swallowing fluids; he could only be prevailed upon to attempt to take any by means of a teaspoon, which he guided to his mouth with his own hands, and each effort at deglutition was attended with a spasmodic gasping, and a sort of convulsive condition. At Mr. Page's recommendation, he was immediately brought to the infirmary, into which he was admitted at about twelve a.m., Monday, February 23rd. Soon after his arrival, he was offered some warm milk and water, his mother remarking that he always swallowed cold fluids with greater difficulty. After many ineffectual attempts (during which he took up the spoon, but before he could convey it to his mouth, turned away with a convulsive shudder, and a peculiarly despondng expression), he succeeded in swallowing a small quantity, without much apparent difficulty; after the first two or three mouthfuls, however, each attempt produced a convulsive gasp, and was made in a hurried alarmed manner. He was at this period, as he had been throughout his illness, perfectly sensible and conscious, his tongue clean and moist, his skin moderately perspiring; he complained of no pain in any part of his body, and the cicatrices of the sores, which had all completely healed, were looking healthy, and presented no unusual appearance; his eyes, at times, had a somewhat wandering aspect, his pupils were much dilated; he frequently started, as though frightened; his manner was extraordinarily anxious and excitable, he seemed totally unable to keep himself quiet, and there was a peculiarly hurried character about all his actions, which it is impossible to describe. In the course of the afternoon, the symptoms slightly diminished, he was able occasionally to take a few teaspoonfuls of broth and tea, and he also contrived to eat an egg, but towards nine p.m., they recurred to as great, and greater an extent than previously, and Mr. Page determined to try the effect of chloroform, it was therefore immediately administered, and its action kept up for an hour; on allowing its influence to subside, the symptoms returned, and it was evident the progress of the disease was unchecked. He was even more restless than formerly, and although at his own request some tea was offered to him, he was totally unable to swallow it, or even to bring the spoon to his mouth, the effort to do so throwing him into a convulsion, his eyes almost starting from his head, and the spoon grasped firmly by both hands, being held out at arm's length before him. At eleven o'clock the administration of the chloroform was resumed, and continued with but little intermission for eight hours. Whilst under its influence he remained perfectly quiet, breathing moderately, with his pulse full and regular, though rapid, 120 and upwards; on allowing its effects to pass off, however, even in a slight degree, violent spasmodic action of the muscles of the throat ensued, and laboured respiration, apparently from the accumulation of tenacious mucus in the air-passages. At seven a.m. on Tuesday morning, the administration of the anæsthetic was suspended; the child soon recovered consciousness, but was unable to articulate; each act of inspiration was attended with a convulsive spasm of the muscles of the throat, including the sterno-mastoidei, and an extensively diffused mucous rattle; his countenance, from having been quiet and motionless, soon became anxious and troubled, he struggled and gasped for breath, his limbs were disturbed by convulsive starts, the teeth ground against each other at each inspiration, through spasm of the muscles of mastication, a quantity of tenacious mucus accumulated about the mouth and air-passages, occasioning great uneasiness, and increased difficulty of respiration, and he died at length, thirty-five minutes after the chloroform had been laid aside.—*Prov. Jour.*

REVIEWS AND NOTICES OF BOOKS.

A TREATISE ON THE DISEASES OF THE CHEST; being a Course of Lectures delivered at the New York Hospital. By JOHN A. SWETT, M.D., Physician to the New York Hospital, &c. New York. 1852. 8vo. pp. 585.

THE lectures which compose this volume appeared originally in the pages of the *New York Lancet*, and the author states that he has been induced to publish them in a separate form at the solicitation of many medical friends, "the whole subject having been carefully revised, and the experience of ten years in hospital and private practice added."

The first part of the volume is devoted to diseases of the lungs; the remainder, to diseases of the heart and thoracic aneurism. The author commences by giving a *resumé* of the physical and rational or constitutional signs of diseases of the lungs; he then considers, in succession, bronchitis (under which whooping-cough is treated of), pneumonia, pleuritis, laryngitis, emphysema, phthisis, and cancer of the lung.

As it would, of course, be out of our power to notice in detail the many important subjects included in this part, we shall be content for the present to call attention to the author's account of "cancer of the lung," contained in the two latter lectures, in which he has given the details of three cases of this rare form of disease; and has added a summary of seventeen other cases from various sources.

Cases of cancer of the lung naturally divide themselves, Dr. Swett observes, into two classes: in one, the lung itself is the seat of the deposit, and the symptoms are those of pulmonary irritation and oppression; in the other, the cancerous deposition takes place in the cellular tissue of the mediastinum, and the symptoms are rather those of pressure than of irritation.

The following are the symptoms laid down by the author as characterising cancer of the lung:—

"Cancer, when it attacks the substance of the lung, commences very insidiously. There may be slight cough, dry, or attended by a trifling mucous expectoration, some dyspnœa, and almost always pain in the chest. In the progress of the case, the cough and expectoration become more decided; the dyspnœa and the pain in the chest become also more frequent and severe. Hæmoptysis also frequently ensues. The constitutional symptoms are usually decided. Emaciation and loss of strength ensue; the pulse sometimes becomes acceler-

ated; the countenance assumes a peculiar straw-colour; the superficial veins of the neck, of the chest, or of the abdomen become enlarged; œdema of the face, or of one or of both arms, ensue, often with œdema of the lower extremities; and the patient dies, worn out by a gradual exhaustion of the vital powers, and with a constantly increasing dyspnœa, aided, perhaps, by the development of a low inflammatory condition in the chest, or in the abdomen.

The physical signs are dulness on percussion, according to the seat and the extent of the cancerous deposit, often, however, existing over a whole lung, and of a very decided character; a bronchial respiration, increased vocal resonance, and sometimes a rhoncus, and less frequently a mucous rattle. Besides, you will often find the affected side of the chest to be smaller than the opposite side. It is contracted, either throughout or in some portion of its extent, and often moves less in respiration than the healthy side. It is probable that, in certain cases, the condensation of the pulmonary tissue may be carried so far that the bronchi even may be obliterated, and then, with great dulness on percussion, you would have an absence of all respiratory sound."

The author next calls attention to the diseases with which cancer of the lung may be confounded, and points out the diagnostic signs. The diseases for which it may be mistaken are—phthisis, empyema, and aneurism of the thoracic aorta.

"In *phthisis*, the disease often commences with nearly the same symptoms, and progresses in a similar manner; and even the physical signs may be quite analogous. Yet, in most cases of cancer, there are some anomalous symptoms which are not met with in phthisis. Thus, in the case to which I have alluded, there was severe neuralgic pain extending down the arm, which at once made me doubt the existence of phthisis. The pulse was also quite natural in frequency, which could certainly not be expected in a case of phthisis so far advanced, and there was no hectic. The absence of hectic symptoms and a tranquil pulse seem to be rather striking characteristics of cancer before the period of softening—a condition which probably does not often occur until a late period of the disease. A leading fact in the history of tuberculous disease is, the great uniformity of its seat at the summit of the lung, and its tendency to pass to the formation of cavities. Neither of these facts are true in cancer. Again, tuberculous disease in its progress most frequently affects both lungs, so as to be recognized by the physical signs. This is not the case with cancer. The physical signs are seldom detected in more than one lung. Again, the symptoms induced by pressure upon the veins are not observed in phthisis, as they not unfrequently are in cancer of the lung. Œdema of the upper regions of the body, and enlargement of the superficial veins, are not likely to occur in phthisis.

In *empyema* the affected side of the chest is usually dilated; there is always extensive dulness on percussion, and absence of respiratory murmur, unless at the apex and at the root of the lung. In cancer of the mediastinum, precisely the same physical signs may exist; and in both diseases you may notice an œdema of the upper portions of the body and enlargement of the superficial veins. . . . . In cancer of the substance of the lung, the affected side is usually contracted and very dull, and a bronchial respiration is heard over it. This character of the percussion and of the auscultation is sometimes met with in empyema, but it is rare.

Cancer of the lung may be confounded with aneurism of the aorta, or with valvular disease of the heart. If a cancerous mass, too small to produce any external tumour, is infiltrated around the origin of the great vessels of the heart, and compresses them, the physical conditions of a permanent organic bellows murmur are produced. . . . . Finally, in all suspicious cases, be careful to examine other portions of the body: the abdomen, the subcutaneous organs, and perhaps you may discover a tumour, or many tumours, which will aid you materially in the diagnosis."

Diseases of the heart form the subject of eleven lectures. This part commences with an outline of the anatomy, physiology, position, &c., of the organ; followed by an account of the physical signs in health and disease. The author then treats, in succession, of pericarditis, endocarditis, enlargement of the heart, including hypertrophy and dilatation, valvular disease, carditis, induration, softening, and rupture of the organ.

In the chapter upon the "medical anatomy and physiology of the heart," the author calls attention to the necessity of determining as nearly as possible the precise situation of the valves and orifices, and he gives the following as the result of Dr. Pennock's experiments:—

"If a needle be passed perpendicularly to the plane of the sternum through the middle of that bone, opposite the middle of the cartilage of the third rib, it will penetrate the *aortic valves*. If the wires be passed perpendicular to the tangent of the curved surface of the thorax, between the cartilages of the second and third ribs, half an inch from the left margin of the sternum, the semilunar valves of the *pulmonary artery* are entered. The *mitral valve* commences beneath the lower margin of the left third rib, near the junction of its cartilage with its osseous extremity (two and a half to three inches to the left of the sternum), and runs slightly downward, terminating opposite the left edge of the sternum, where it is joined by the upper margin of the cartilage of the fourth rib. The *tricuspid valve* extends obliquely downwards, from a point in the middle of the sternum, immediately below the third rib, to the right edge of the sternum, where that bone is connected with the lower margin of the cartilage of the fifth rib."

Two lectures are devoted to pericarditis, in which we have a sufficiently full description of its pathological anatomy, symptoms, and diagnosis. The disease appears to be of as frequent occurrence in New York as in this country, and is observed likewise under the same morbid conditions of the system. The deaths from this cause Dr. Swett states to be about one in 425 of the general mortality. "The Report of the City Inspector of New York during three successive years, gives (he observes) 108 deaths from inflammation of the heart. These were, probably, all cases of endocarditis and of pericarditis, no attempt having been made to distinguish them in the Report. Of these cases, 49 were males and 59 were females; 44 cases occurred from June to December, 64 from December to June; 19 cases were under ten years of age, 56 cases between ten and forty years of age, and 35 cases were past forty years of age."

In the lecture upon "enlargement of the heart," the author treats of hypertrophy and dilatation together, and gives his reasons for adopting this arrangement as follows:—

"Most authors who have written upon the diseases of the heart seem to me to have been too systematic in their arrangement of this subject; and strange as it may appear at first sight, have rather confused than simplified the matter. Thus, they treat in distinct chapters of hypertrophy of the heart, dwelling at length upon its symptoms, diagnosis, and treatment; in the same manner they treat of dilatation of the heart, forgetting that in a great majority of cases these two conditions are united, and that of course their history, diagnosis, and treatment are blended. Now, while I readily admit the existence of simple hypertrophy, as found in a certain number of cases after death—few, indeed, in comparison with the whole number of cases—yet I doubt very much whether there are any certain indications, either rational or physical, by which you can determine its existence during life. This is still more strikingly true of simple dilatation of the heart. This form of disease undoubtedly exists, but it is, in my experience, exceedingly rare. The same remarks apply also, I think, to the attempts that have been made to distinguish enlargement of the right side of the heart from that of the left side. I do not doubt that this may sometimes be done with a certain degree of success, but not always; and when it is done, I do not know that it leads to any practical result. Let me impress upon you that the great object is to ascertain the simple existence of enlargement of the heart. This is all that you can do in very many cases, and it is the great practical fact to be ascertained in almost every case. I wish to be understood as leaving entirely out of the question the subject of valvular disease, which is quite another matter."

The two last lectures are devoted to aneurism of the aorta; and, in an appendix, the author has given some extracts from Lebert's work on Pathological Physiology. We must, however, draw our notice of Dr. Swett's treatise to a close; we cannot do so, however, without saying that the volume, taken as a whole, is highly creditable to the American press, and will bear comparison with any treatise on the same subjects which has appeared at this side of the Atlantic.

THE BRITISH POLYTECHNIC FIRE.

Nothing perhaps has been sought after with greater solicitude, in the mechanical contrivances applied to medicine, than an efficient and easily regulated method of heating sick rooms. In a variety of diseases such an object is of the most essential importance.

From a certain arrangement of materials, which we had the advantage of inspecting, at the Royal Polytechnic Institution, on Saturday evening last, this most desirable end seems to have been perfectly accomplished. The apparatus, which is to be called the "British Polytechnic Fire," has been patented by its inventors, Dr. Bachhoffner and Mr. Defries, the latter gentleman a well-known authority in all matters relating to gas.

The apparatus is thus constructed:—Thin strips of the metal are supported on a framework, from which ignited jets of gas issue, and the whole mass becomes instantly red-hot, while the heated escaping vapour adds so perfectly to the illusion, that, at the distance of a few feet, it is impossible to distinguish this arrangement from an ordinary bright coal fire. One of the circumstances likely to lead to the general adoption of this apparatus, is, that it may be applied to our common grates at a very trifling expense; all that is necessary being to lead from the main, into each stove, a pipe for conveying the gas. This pipe, it may be remarked, is not liable, like those conveying common gas, to become choked, as from the non-carbonized gases proposed to be used, there is absolutely no deposition. The results obtained are thus stated by the patentees:—

"Entire absence of all dust, dirt, smoke, or smell; the immediate production of a bright fire at any hour of the day or night, by merely applying a lighted taper; perfect adaptation to culinary purposes; no danger of fire from sparks, or the falling of red-hot coals, nor from chimneys on fire: regulation of the temperature of the sick-room to the utmost nicety; requiring but little attention or cleaning; a great saving of time in stirring and throwing on coals; and no annoyance from its going out."

It admits of the introduction of materials in the formation of fire-places, which cannot be employed under the present system of coal fires. From the entire absence of smoke, the atmosphere of London will remain as free and uncontaminated (so far as our fires are concerned) as in the purest country district, and would meet the demands of the recent legislative enactment, which requires every furnace to consume its own smoke. The cost, to the public, of the gas will be about eighteen-pence per 1000 cubic feet, and will thus fall below that of coal. The gas is proposed to be obtained by the decomposition of water during its passage, in the state of steam, over red-hot charcoal.—*Lancet.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, APRIL 7, 1852.

REMUNERATION FOR MEDICAL SERVICES.

It is every day becoming more and more obvious that practising medicine for the "honour of the thing," is a delusion; and that doing so with the hope that at some time or another a character acquired by this means may be remunerative, is also a mistake. Men who have succeeded attribute their success to their hospital opportunities, and perhaps to their gratuitous services in private practice; but in the progress of such a system, the people learn that medical relief may be had without paying for it. At the moment we write, the principle upon which such a belief is founded is recognized by the legislature, and carried into effect by the executive. Doctoring for nothing is the order of the day, and all are anxious to avail themselves of this pleasant state of things; yet at the same time, the evil carries its cure with it. Patients discover that it is dangerous, and doctors that it is destructive. So do we find such articles as the following expressing the opinions prevailing on the subject, where formerly very different views were entertained. We direct attention to this matter with the hope that our struggling brethren throughout the country may profit by it. As long as metropolitan physicians and surgeons do so, so long will provincial ones be expected to do the same:—

The subject of payment to the medical staff of hospitals has naturally excited much interest, both within the profession and among the governors of our metropolitan hospitals. This is just what we desire. If the payment of the medical staff can once be introduced as a subject of discussion, we have no fear for the result. No doubt objections will be urged, but these must all melt down under discussion. We shall, no doubt, be told by some that there are no funds; where these are abundant, it will be said the executives have no power to employ them for such a purpose as that of remuneration to medical men. When there are no funds, they should be obtained, as in the case of the Royal Free Hospital; and when the hospital incomes are superabundant, it is monstrous to say that the hard-working medical officers shall be the only persons, from the porter to the treasurer, whose labours are gratuitous. Another objection readily foreseen, is the great competition for hospital vacancies when they occur. This point is constantly urged by selfish and inconsiderate governors. It may be said to those who ask for some recognition of the value of medical services, "You may resign; we can easily find successors." To this the reply is, "Establish the system of election by concours." This would close the comparatively easy access through the portals of most hospitals. There never will be found a superabundance of first-class men in the medical, or in any other profession. These remarks apply to the senior officers of those hospitals which do not remunerate their medical staff; but it applies still more forcibly to the assistant medical officers. The senior appointments may lead to practice; the junior rarely, if ever, do so. The lives of most of our assistant physicians and surgeons of hospitals, and the physicians and surgeons of non-paying dispensaries, are indeed most dreary and heart-sickening. They are far worse off pecuniarily than the moderately successful surgeon in general practice. Taking the consulting walk of medical life for comparison, we may safely assert, that in no art or profession known, is so much time and mental and bodily toil required to ensure success. Before concluding these observations, we beg to draw the attention of the profession to the Report made by the members of the Government Commission appointed to inquire into the public charities of this country. In this Report, after stating the usages of the different hospitals in regard to the payment of their medical officers, the commissioners observe:—

"The mode of remunerating services above mentioned may occasionally impose upon the governors the alternative of wholly neglecting to reward the discharge of very onerous duties, or of appointing to the situation of principal, an assistant medical officer who has not shown himself peculiarly qualified for an office which the governors are yet in some degree bound to bestow upon him. Other considerations, also, of the highest importance, and perhaps too little regarded in the hospital system of this country, render the practice of giving to medical officers no, or insufficient, salaries, inexpedient; it deprives them of the means of devoting their leisure hours to the improvement of medical science, and of relieving the numerous and afflicting cases of real distress which are perpetually falling under their notice."

In respect to this latter argument, we may observe, that those distresses which are published in our police reports, and responded to with such liberality by the public, are constantly paralleled, and more than paralleled, in the experience of hospital medical men.—*Lancet.*

The following has reference to the same subject:—

There must have been an error, either in my manuscript or in the printing of my letter in your number of March 6th. The sums put down as paid to the assistant physicians and surgeons at St. Luke's, London Fever Hospital, and Small-Pox Hospital, should have been put down as paid to the senior physicians and surgeons; also, in the list of dispensaries we should read physician and surgeon for assistant-physician and assistant-surgeon. The error, however, is immaterial, as the real question at issue is, not how much certain hospitals pay, but what hospitals do not pay at all. In continuation of the list, I have to add—Guy's Hospital, physicians and surgeons £40 each; assistant-physicians £100. The Eastern Dispensary, physician £50. Bishops-court

Dispensary, physician £50. The Lock Hospital and the Charing-cross Hospital have the unenviable notoriety of being added to the *non*-paying list. You are quite correct in your statement "that in some of the institutions named in the second list, the medical officers divide amongst them the fees of students." This is the case also at St. Bartholomew's, Guy's, St. Thomas's; indeed, this practice may be taken as the rule at all the metropolitan hospitals. But it is most important—and I beg to urge this point strongly upon you—to remember that in no one case do the assistant-physicians and assistant-surgeons share in this division: *only the seniors*. Nor have the assistants any claim to a share. We see, therefore, that in the hospitals in the second list, the assistant physicians and surgeons receive no remuneration in any shape or form. In the consideration of the subject, therefore, as respects the assistant physicians and surgeons, the pupils' fees for hospital attendance are not to be considered. Even with the full physicians and surgeons, these fees ought not to be calculated upon, as their amount varies annually; indeed, it would add to the dignity of the staff if no such fees passed directly into their hands, but were considered hospital property, and an equivalent salary given to both seniors and assistants. There would be more independence of feeling in both parties. When the time comes—and sooner or later come it will—that all the hospitals and other charitable institutions shall pay their medical staff, arrangements must ensue between the seniors and juniors; for of course the assistants cannot be paid directly from the funds, or any other fund, of the hospital, without the concurrence of the seniors; but which of course would be at once granted by the latter, and therefore any necessary arrangement on this point may be safely left to the parties principally concerned. I see that there is already organized in St. Mary's Hospital—an institution which has not yet been one entire year in working order—a "Clerical Endowment Fund." I have no invidious feeling on this matter, and I disclaim all desire to contrast spiritual with medical advice given in hospitals, but I cannot forget that those institutions were, and are, not established for the former, but essentially for the latter purpose; therefore, *à fortiori*, the medical staff deserve remuneration; and we can only attribute the previous neglect of the public to an imperfect knowledge of the facts.—*Letter in Lancet.*

WORKING OF THE DISPENSARY ACT.

We receive from all parts of the country grievous complaints as to the working of this measure. Inadequate salaries, excessive dimensions of districts, and the book-keeping imposition, are the principal subjects of comment, but many others are added. During such a revolution, much of this is inevitable; but much may be corrected, and the moment the dispensaries are established and the appointments made, the work of revision must commence. Of the "books," there seems to prevail but one opinion. They cannot be correctly filled, if filled at all; and even if ever returned, will prove utterly worthless. We have denied, and we still deny, that the Commissioners have any power to impose such a duty. The Dispensary Surgeon is appointed to afford medical relief to the poor, not to prepare medical statistics. It may be argued that a general power to make rules enables the Commissioners to impose this duty; but if this be so, they may impose any duty however foreign to the service. Our belief is, that these books were invented by some one looking for a "post" to demonstrate his official abilities; others say that they are nothing but a printer's job. Here is an extract from a letter on the subject:—

The "ledger library" of the Commissioners, furnished to each dispensary, will deter many men from continuing in office. I heard yesterday that a surgeon in the ——— union was occupied one day last week, from ten in the morning to six in the evening, filling up the reports and headings in the several books.

Here also is an illustration:—

Sir,—This is the first time I have attempted to address you, or indeed appear in the public press, my motto always being *Ne sutor ultra crepidam;* but circumstanced as the medical officers of dispensaries in this part of the country are, I feel that silence on their parts would be anything but honourable or spirited. £60 per annum for a dispensary district of at least a population of 9000, and an area of no one knows how many thousands of acres! Ready night, noon, and morning for all calls, and those tickets issued by parties who may be your personal enemies! Take, for example, my case. In the year 1849, I had a salary of within a few pounds of £100; this year I am to have three quarters' salary at the rate of £60. Without the dispensary, I could attend my private practice on foot, with an occasional horse and car; with the dispensary, I *must* keep a horse. The dispensary will not support me; independent of the dispensary, my private practice cannot do it. Hold the dispensary, and keep a horse and man, you will have at least to pay for the support of the two latter £30 per annum; the balance of £30 will be for me for risk of life, interest of money expended in my profession, and eighteen years lost in the pursuit and practice of the same. I ask you, sir, is it not too hard? You may ask what remedy I propose? I would answer in full, did I not fear to dip too deep into politics. However, I do not attach any blame to the boards of guardians—they ought to be as economical as possible—to the Poor-law Commissioners I attach no blame, but to the Irish Members of Parliament I attach all. If you refer to the lame argument of Sir William Somerville at the discussion on this bill, you will find him stating that the reason the medical charities of Ireland were not paid for as *many* of the English and Scotch, was owing that we got an *equivalent* in the way of *national education*. Now, I submit, that a sum not exceeding £30,000 would give the medical superintendents a moderate salary of between £90 and £100 per annum, which ought to be paid out of the Consolidated Fund, the guardians supplying all medicines, and medical and surgical appliances.—I have the honour to be, sir, your obedient servant,

J. M.

MEDICAL ETHICS.

We copy the following, not because we wish to express any opinion on the matter, knowing little of it, but because we are anxious to provoke discussion on such subjects. Never, in the history of our profession, has there been such necessity for scrutiny as at the present moment, and everything we can do shall be done to promote it:—

To the Editor of the Lancet.

Sir,—I request insertion of the enclosed correspondence in your journal, which is ever ready to maintain the etiquette, the proprieties, and, through these, the honour and efficiency of our profession. I should not obtrude myself did I consult my own tastes, and that love of privacy and even tenor of life which thirty years of country practice have confirmed. But as my antagonist talks of his "position," it seems to me a duty to obviate any mischief which might affect the profession through erroneous views taken by a person of his "position." General practitioners must keep sight of the delicate character of consultations, and claim their complete and equal dignity therein with persons of whatever position. They must not suffer consultant-physicians, the moment their backs are turned, to reënter alone the sick chamber, which is the peculiar privilege of the family surgeon. No consultant, whatever his position, has a right to enter the sick chamber before the arrival of the ordinary attendant, nor to remain therein after his departure. This is the rule; and in this case, and from this correspondence, it will be seen that no reason existed for a deviation. In this case the physician suggested that I should leave the house first: "Pray do not wait—your time is precious," or some such courtesy. If he desired to witness the effect of the first dose of wine, had he warned me, *I* would have witnessed also. Was I nobody? If it had been decided that the inunction was not material, why run up stairs to repeat the decision? I say, if he assumed the right to witness the effect of his prescriptions, I claim the right of cotemporary inspection. He is not alone in the case. In this affair the peculiarity is, that the surgeon is bowed courteously out of the house; that no fresh symptoms are reported; no fresh summons despatched to the physician waiting for his carriage; but that, spontaneously and alone, he reascends to the sick chamber, without the essential to a consultation—the presence of the other practitioner. If this be the new style of consulting etiquette, let my brother surgeons know it; let them insist on their

own presence—*constant presence*—with the consulted person; and let them, to ensure this essential justice, and instructed by this case, take very good care, before they leave themselves to see the physician off the premises.—I am, sir, your obliged servant, HORACE HOWARD.

New Buckenham, Norfolk, March 22, 1852.

New Buckenham, Feb. 26, 1852.

SIR,—On the next visit to my patient, Mr. Lain, after our consultation, I found him worse, and almost comatose. On inquiry as to the probable reason of this change, I was told that you had reëntered the sick apartment after my departure, had given wine with your own hand (a quantity at *once* which I with difficulty conceded should be diffused over twenty-four hours), and prohibited the inunction, which at the consultation it was agreed should be kept up. I am compelled to inquire whether it be true that you did thus intrude into the sick room *alone*, and did nullify the consultation in a manner so unprofessional and contemptuous of the practitioner in regular charge of the case? I request an immediate reply.—I am, sir, your obedient servant, H. HOWARD.

Dr. Ranking.

Norwich, Feb. 27, 1852.

SIR,—The tone of your letter of this morning might well excuse my committing it to the flames without reply; but I will overlook the uncourteous terms in which you express yourself, and answer your questions *seriatim*. I did give the patient some wine and water, after you had left, with my own hands, and I did so advisedly, as I wished to note its effect upon the pulse. The quantity was no more than was reconcilable with the implied object agreed upon in consultation. I did, also, in conformity with an opinion I gave you, in reply to your own question respecting the propriety of inducing mercurial action, inform the friends that we did not consider the inunction materially important. So far in answer to your questions. In reference to your evident wish to palliate your own most indefensible conduct by affixing upon me the charges of "unprofessional" and "contemptuous" treatment of yourself, by "intruding," as you are pleased to term it, upon the patient after your departure, I shall content myself with observing, that in this, as in all other professional transactions, my conduct is open to the inspection of my medical brethren. Assuredly, however, this conduct, dictated by the wish to satisfy myself of the advantage of an important modification of the treatment of the case, suggested by me, *and agreed to by you*, did not justify your impugning my judgment in the rude manner in which I am told you did, neither your denial that you had sanctioned the use of wine, nor that another dose of it would have destroyed the patient. Still less could it justify your heartless remark to the sorrowing parents, that the fee for my attendance had been thrown away. As to the abstract propriety of giving wine under the circumstances, I think I may safely, and, I hope, without presumption, allow my judgment to be at least equal to your own. I do not hesitate to assert my conviction, that of the small chance which the poor patient had of recovery when I saw him, he was deprived by the withdrawal of stimulants. In conclusion, I will not, on slight acquaintance, do you the injustice to suppose that you will not, on reflection, see the propriety of apologizing for rudeness as unprovoked as it is, I am happy to say, strange to me.—I am, sir, your obedient servant,

H. Howard, Esq. W. H. RANKING.

New Buckenham, Feb. 29, 1852.

SIR,—You admit that you gave the wine and forbade the inunction. Again I ask, *why* was the wine given the moment my back was turned? *Why*, as the inunction was agreed upon at the consultation, was it prohibited the moment I left the house? In fine, *why* did you nullify a consultation by your sole authority, directly that consultation was closed? I have, sir, yet to learn that this proceeding can be reconciled with professional customs and propriety. As to my expression of pleasure that the friends had abstained from a second dose of wine, it was meant as an approval of their caution, not as a critique to them upon your skill. As to my son's remark, or some such, that the expense of the consultation was to be regretted, he commissions me to say that, whatever were his words, *he meant* simply to express a fact, not to reflect upon your judgment.—I am, sir, your obedient servant. H. HOWARD.

Dr. Ranking.

Norwich, March 2, 1852.

SIR,—In reply to your last letter, I beg to refer to my former note, in which you will find your questions answered. I will repeat them, in case you have not preserved the communication. I gave the wine *because* it was agreed in consultation, and I wished to see its effect. I counter-ordered the inunction *because*, as it was agreed that salivation was not desirable, and that the mercurial was to be given every four hours instead of every two, it appeared to me as a matter fully understood that the inunction was to be suspended. —I am, sir, your obedient servant, W. H. RANKING.

H. Howard, Esq.

P.S.—I still look for an acknowledgment of error in your remarks to the patient as repeated to me.

New Buckenham, March 3, 1852.

SIR,—What was "repeated" to you by the patient or friends I know not. When they said to me that they had not given more wine, I expressed a simple approval. You talk of this as "error," but would anybody besides yourself perceive not only truth, but an unavoidable reply. But this counter-charge against me does not dispose of my still just complaint against you. You have *not* given me a satisfactory explanation of the original grievance. The facts are undisputed, and from these *we* draw opposite conclusions. You claim a professional right to enter the sick chamber alone, instantly on the departure of the surgeon, *no fresh symptom having arisen*. I deny this right; and as it is necessary for myself and other Norfolk surgeons to understand our relation to the consulting practitioners, whether these gentlemen may subvert a consultation in the way you did, I will submit the matter to the hospital staff if requisite.—I am, sir, your obedient servant, H. HOWARD.

Dr. Ranking.

SIR,—In closing this correspondence, which, if I had consulted my own position, I should not, perhaps, have commenced, I will recapitulate the circumstances. In consultation it is decided that wine is to be given at my suggestion. It is decided that mercurial action is not needed, and the doses are prescribed at longer intervals. While waiting for my carriage, I think proper to witness the effect of the first dose of wine; and I tell the friends that the inunction has been decided as not material at the moment. You, in the most impertinent manner, designate my visit to the patient's room after your departure, for an obvious and useful purpose, as an "intrusion," and accuse me of contravening the consultation. I assume the right of a physician, if he wishes, to witness the effect of his prescriptions, and never heard any reasonable practitioner object to it; and I affirm the statement that I contravened the conclusions of the consultation to be false. I, moreover, repeat, that the expressions used by you in reference to me were such as no conscientious man would have used, except under irritation, which he would have deplored, and I demand an acknowledgment of the same. As my conduct is open to inspection on all points, you may take what further steps you please.—I am, sir, your obedient servant, W. H. RANKING.

H. Howard, Esq.

New Buckenham, March 7, 1852.

SIR,—No dust you may raise shall blind my eyes to our original ground of dispute. I called your conduct unprofessional, and you remain, for aught you have said to me, in an unprofessional position. When, through the verdict of some professional and grave tribunal, you are acquitted, it will be high time to assume the character of an injured person, and to "demand an acknowledgment."—I am, sir, your obedient servant, H. HOWARD.

Dr. Ranking.

MEDICAL TOUTING.

THE Reverend Doctor TODD, "Senior Lecturer," or principal executive functionary of Trinity College, having with praiseworthy disinterestedness taken the case of the Surgeons of Ireland into his serious consideration, we have humbly to direct his attention to a small matter which concerns the welfare of those who are about to seek admittance into the body; either by back or front door. The Doctor, we have no doubt, entertains a most sincere and anxious wish to promote the "reputation, honour, and dignity" of the surgical profession; doubtless impelled as much by hereditary instinct as by a conscientious sense of duty; and we are bound therefore to congratulate our

brethren on this happy union of theology with the "art or faculty" we profess. It is true that, there being nothing new under the sun, there is nothing new in this patronage of surgery by mother church; for as we all know, it is to *frere* Jacques and *frere* Cosme we are indebted for our lithotomy; but new or old, we must be the better of the infusion. The small matter to which we have to direct attention is, independent of its chirurgical bearing, one which falls within the sphere of the reverend functionary's duty as a matter of academic discipline; being in fact a question as to Professors of the University haranguing their classes on disputed questions of medical law, and giving their versions of charters and statutes; interlarded with allusions calculated to foment discord, and with statements respecting passing events not very remarkable for strict veracity. It is not, we believe, usual in any other faculty for professors to appeal to the sympathies of the students in their troubles, and is therefore of doubtful propriety in the medical; but even if permitted "at a pinch," the practice should be conducted so as to save the institution from dishonour. When statements are made to inexperienced students on such topics they should contain the truth, the whole truth, and nothing but the truth; but perhaps the less said the better respecting doubtful matters. It is bad enough for the few surgical pupils who are looking for medical degrees to be obliged to "sit out" the retailing of obstetrical *niaiseries* or chirurgical book stuff, but it is too bad to be compelled to listen to whining appeals, and still more to hear gross misrepresentations. In our last we had to offer a word of advice to the College of Physicians on the effect of these doings, and the danger to be apprehended from any tacit sanction of them. We have now to repeat it, for it surely cannot redound to the credit of that body to remain quiet spectators of such irregularities.

TO THE ADMIRERS OF MR. DENIS PHELAN.

The following frank expression of dissent from the eulogium on this functionary, published in our last, shows the estimation in which such things are held when best understood. If our provincial brethren oftener asserted their independence in the same way, they might perhaps avert evils which otherwise prevail:—

TO THE EDITOR OF THE MEDICAL PRESS.

Dear Sir,—Being the senior physicians of this town and county, we feel it imperative on us to disabuse the minds of the respectable part of the profession on the subject of a letter addressed to Mr. Denis Phelan in the last number of your periodical, and signed "Charles Halpin, M.D., Secretary," inasmuch as we do not belong to any association to which he is secretary, neither do we know of any existing in this county; and we are not disposed to allow our brethren in the other parts of Ireland to suppose the letter alluded to conveys in any way *our* sentiments respecting the (late) functionary of the poor-laws referred to.—We remain, dear sir, your obedient servants,

George Roe, M.D., Surgeon, Cavan Infirmary.
Bernard Coyne, M.D., Physician to Cavan Dispensary.
Wm. Babington, A.B., M.B., Fortview.

CORRESPONDENCE.

THANK-YE INSURANCE COMPANIES.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—Your correspondent "N." has commenced *a good and useful work* in bringing before the profession in Ireland the names of those Insurance Offices that refuse to pay medical men for valuable information *given exclusively for their protection*. To "The West of England" and "Standard," I will now add "The Guardian" and "Sun."

In naming those offices which do not recognize the claims of the medical profession, and which, consequently, should receive no good will in return, I think it equally just to mention those, on the other hand, that trade on a liberal basis, and beg, therefore, that you will kindly insert, for the information of those who may be consulted upon the subject of life insurance by their patients, the names of the following offices which do pay the medical referee:—"The Britannia," office 51, Dame-street; "Church of England," 1, D'Olier-street; "Exchange," 8, Westmoreland-street; "United Kingdom," 4, College-green.

All these are first-rate and most safe companies to insure with, and deserving of professional support.—I remain, sir, your obedient servant, M.

But I also enclose my card for the information of any insurance agent who may suppose that this communication comes from the agents of either of the offices recommended above, and be regarded therefore as an indirect way of seeking to extend their connexion, instead of but the index of what is now the general determination of the medical profession—viz., to refuse in future to give opinions gratis.

MEMORANDA ON AUSCULTATION OF INFANTS.

By Dr. Merei.

1. The respiration of young children is regularly quick and noisy. This must be allowed for.

2. There is much propensity to mucous secretion, and as they do not eject it, mucus accumulates, and causes a great many large and fine râles, which veil the respiratory murmur, and impede us sometimes in perceiving the crepitation in pneumonia, or the rubbing sound *(frottement)* in pleurisy.

3. Mucous obstruction of a large part of the bronchial tubes sometimes occurs, and prevents the perception of the vesicular murmur. This case we enlighten by percussion, as the sound in mucous obstruction is clear, or but very slightly dull. Nor is there true bronchial respiration in these cases.

4. A little child's chest is of small extent, consequently if we auscultate, even at the middle of the chest, our ear is struck by the respiratory sounds of the trachea and of the large bronchial tubes, and there is difficulty in perceiving slighter alterations of the sounds.

5. The child will neither perform a deep inspiration, which sometimes we need to observe, nor will it speak words at our wish and command; thus bronchophony, pectoriloquy, and ægophony, are lost from us: we can only hear sometimes the modified sound of the voice during cries.

In order to get a full inspiration, as full as the child can perform it, I find the best plan the following:—I order the child to be taken in the arms of its mother or nurse, in a position which allows auscultation behind and laterally; then I approach cautiously from behind, and lay one of my hands on the upper part of the abdomen, and exert with it a gradually increased pressure; thus the abdominal viscera pushing the diaphragm upwards, the child exerts its power to overcome this impediment by a more extensive inspiration. If this act is prevented by pleuritic pain, we perceive it by its anxiety or irascible struggle with its trunk and hands and by moans and cries, as far as they are possible. In this manner we should always assist the physical examination of the organs of the chest. The *percussion*, on the contrary, is the most enlightening means of examination in children. The walls of their chest are thin and flexible, consequently we perceive more immediately the sound of the pulmonary texture, and even its consistence.

If we are aware of the above-mentioned circumstances, by and by, with patience, careful exercise, and intelligent combination to all that we see and hear, and of all that we feel with our percussing fingers, we cannot fail to arrive at a high degree of certainty in this sort of diagnosis.—*Ranking's Abstract.*

ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that on the 2nd of August, 1852, the Council will proceed to elect a Curator of the Museum from among the Fellows or Licentiates of the College.

Candidates will be required to lodge at the College on or before the 24th of July next, such Preparations, in Human and Comparative Anatomy, made by themselves, as they may consider best calculated to demonstrate their skill and abilities.

Information respecting the emoluments and duties of the office may be obtained by application to the Registrar at the College.

By order of the Council,

H. MAUNSELL, Secretary.

Dublin, April 2, 1852.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that on Tuesday, the 4th of May next, at the hour of Two o'Clock, the President and Council will proceed, according to the provisions of the Supplemental Charter, to elect, from among the Fellows of the College,

Three Examiners in Medicine and Surgery;
Two Examiners in Anatomy and Physiology;
One Examiner in Materia Medica, Chemistry, and Medical Jurisprudence;
One Examiner in Midwifery.

Candidates are requested to lodge their applications at the College on or before Thursday, the 29th of April.

By order of the Council,

H. MAUNSELL, Secretary.

Dublin, April 2, 1852.

THE REVERSED AND DOUBLE-ACTIONED PATENT TRUSS.

Invented by FRNACIS L'ESTRANGE, Esq., F R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the medical profession and the public to this Truss. He can state with confidence it is the only instrument constructed on scientific principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT

G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

Dr. JACOB in the chair.

ON THE EMPLOYMENT OF CHLOROFORM IN MIDWIFERY.

By Dr. BEATTY.

IT may be in the recollection of some of the members present, that a paper, written by me, was published just two years ago in the *Dublin Quarterly Journal*, the object of which communication was to testify to the value and safety of the use of chloroform in the practice of midwifery, and to point out how this new and powerful agent might be employed in conjunction with the ergot of rye, another medicine of immense importance in obstetric practice. Since that time I have continued to use chloroform very extensively, and with the happiest results. I have given it to every patient who desired to have it unless I saw some good reason to refuse. I have not pressed it upon any, and I am happy, at the end of two years' additional experience, to be able to state that in all cases its use has been productive of the greatest relief and happiness, and that in no case has anything unpleasant occurred to either mother or child during its administration, or subsequent to delivery. Several patients, after being confined under its influence, have come back to Dublin in subsequent pregnancies from great distances, some from remote parts of England, in order to be treated in a similar manner; and there are many whom no consideration would tempt to undergo a labour without it. It will be easily imagined that my confidence in the power of the agent has increased with my experience, and I now feel distressed when obliged to witness the sufferings of a patient, prolonged perhaps in a first case for hours, when I have the power to alleviate her agony, and (without for a moment interfering with her consciousness) to render her labour a "pleasure," "happiness," or "heaven,"—phrases which have been frequently made use of to me by patients to whom chloroform has been administered.

The application of chloroform in midwifery is very different from its employment in surgical practice. In the latter, we have a person not suffering any pain on whom a painful operation is about to be performed, and in whom it is desired to induce such an amount of insensibility as will render him unconscious of the proceedings of the operator. The sopor in such a case is much deeper than any that is necessary in obstetric practice. The time during which anæsthesia is required is usually much shorter, and the more intense effect of the chloroform is therefore more safely produced than if it were to be continued during the length of time sometimes necessary in labour. In midwifery, on the contrary, the use of chloroform is not begun until the patient is already, and has been probably for some hours, in a state of suffering. The object in such a case is to relieve existing pain; and it is a fact no less remarkable than true, that a smaller amount of the narcotic vapour is required to effect this, than to render a non-sufferer insensible to a painful operation, and a larger amount is subsequently borne with impunity. For this reason it is that when a pure drug is employed, a very few inhalations from the apparatus which I now employ are sufficient to produce a decided effect upon the sufferings of the patient, and a relief so marked as to be spoken of with the greatest satisfaction and gratitude, is obtained long before any approach to insensibility is perceived.* But

* Since the time this paper was read before the Surgical Society, I have seen in the DUBLIN MEDICAL PRESS of the 24th of March, a quotation from a communication in the *American Journal of Medical Sciences*, by Professor Byford of Evansville Medical College, U.S., which bears upon this point:—"I am led to believe that, in estimating the beneficial or injurious influences likely to be exerted by this powerful medicine, our attention has not been sufficiently directed to the *condition* of the *nervous* system, particularly in regard to the presence or absence of pain, or other preternatural excitement. I apprehend that we will find the same laws governing our physical system to obtain with respect to its use as we are compelled to take into account when we call to our aid any of the powerful narcotics, one of which laws is the preservation, in a great measure, of the general system, by the nervous system being preoccupied by exalted or morbid excitement. This principle may account for the fact, borne out, I think, by statistics upon the subject, that the untoward and melancholy effects of chloroform seldom if ever occur in cases where the system is labouring under great pain, as for instance, labour, toothache, &c."

this is not enough for the occasion, the effect has to be kept up sometimes for many hours, and if a sopor as deep as that induced for surgical purposes was necessary, no doubt the proceeding would not be unattended with danger: but fortunately in midwifery practice no such amount of narcotic influence is required. The slow and gradual administration of small quantities of the vapour, renewed from time to time, as required, will be sufficient to keep the patient in a tranquil happy state, in full possession of her consciousness, for hours together, talking to her friends about her, knowing well when a pain is coming on, applying the inhaler to her lips, and asking to have the chloroform replenished when its effects are diminished by its consumption.

The course of a labour treated with chloroform is usually as follows. Take, for instance, a first case, in which labour has been going on for eight, ten, or twelve hours, with that increasing amount of suffering which all females experience until the os uteri is nearly dilated. At this time we know that the pains usually become most severe; and the patients lose their self-control, becoming uneasy, impatient, and loudly complaining of the sufferings which they undergo. If we now commence the judicious use of chloroform with a patient, under these circumstances, the first effect, after a few inhalations, is calmness. Instead of tossing about in the bed, she becomes perfectly quiet, she experiences relief, and the friends who are standing around begin to be astonished at the almost instantaneous effect that has been produced. They had become anxious at the amount of suffering she seemed to be undergoing, and they are surprised at the calmness which has been brought about through the assistance of chloroform. I would say that in eight cases out of ten, the patients express the most exalted kind of satisfaction at the relief thus obtained. They sometimes say—"Oh! this is so delightful, so pleasant;" in fact, a feeling of inexpressible happiness is produced in most patients by inhaling the chloroform, for perhaps two or three minutes, in the way I will presently mention. I have seen a patient, who was tossing about in her bed, perfectly uncontrollable, because to a certain extent delirious, as they often are; I have seen such a patient lie calmly and quietly down, without any stage of excitement, and remain so for the space of four or five hours without for one instant losing her consciousness or self-control, or making loud exclamations, or removing herself from the position in which she was directed to remain.

The next effect which is produced by the judicious administration of chloroform is the total disappearance of that horrible aching in the back which patients complain of in the intervals of the pains, and which makes them call on the nurse in attendance not to relax the pressure which it is usual on such occasions to make on the back. This intolerable ache is never felt after the administration of chloroform has begun; so long as it is kept up, the distress is done away with. After some time, the patient will call out loudly for more chloroform, feeling the benefit which she has derived from the previous administration of the agent. We accordingly let her have a little more, and by degrees she becomes conscious of the approach of the pains, she takes the medicine again, and in this way passes hours without suffering. Some patients will sleep in the intervals of the pains. We know how valuable such natural rest is during labour; and I have observed that the administration of chloroform does not in the least degree interfere with it; on the contrary, it rather helps to produce natural sleep, when not pressed to the extent of sopor or insensibility. As the time of delivery approaches, the amount of chloroform to be given should be rather increased, because the patients suffer more at this time than at any previous stage of their labour; and it will require a larger amount of chloroform for the purpose of alleviating pain, though not enough to produce the full effect which is produced in surgical practice: in fact, I can testify most distinctly that in no case will it be necessary to produce sopor or stertorous breathing in the course of the labour; and it is worthy of remark, that the patients, when the labour is over, will tell you that they knew they had the pains, but did not feel them. In this way, I have known patients to be delivered of their child without their own knowledge. In one instance, the lady had the chloroform for the second time. The first time she had it for two, and on a recent occasion for four hours. On the latter occasion she was conversing with me during the whole period of her labour, and was perfectly conscious all the time. Nevertheless, her child was born, and she was not conscious of the fact, nor of the particular moment when it took place. Another case which occurred more recently was even more striking. It was the case of a lady who had her first labour, which was a very long, painful, and difficult one, about a year previously, without chloroform. Upon the second occasion, which happened during the last month, she begged to have the chloroform, and she had it accordingly for four hours. As many patients do, she held the apparatus herself during the greater part of the time in her hands, and it was so difficult to get her to inhale the chloroform properly, that I was obliged to make her hold her nose with her own fingers, in order to make her breathe through her mouth, which of course she could not have done if she had been in a state of insensibility. While thus employed the child was born, the umbilical cord was tied, and the nurse was sitting at the fire with the infant in her arms, without its mother being in the slightest degree conscious of what had taken place; and in about five minutes afterwards, this lady turned round in bed, and said to me, "Do you think it will be soon over?" I replied, "Don't you know that the child is born!" and I will never forget the expression of her countenance, when she said, "Now, don't deceive me, but tell me truly, will I soon be well." In short, it was not until the child was placed in the bed with her, that she could be made to believe that her delivery had been accomplished, and she then declared most solemnly that she had not the slightest idea, till that moment, of what had taken place.

When effects of this kind are experienced, I need not say that those with whom chloroform has been once used would not on any account undergo a labour without it; and as I before stated, many ladies have come from distant parts of England and other places to obtain the benefit they expected from its administration. No ill effects have ever happened, as far as I am aware, to either mother or child.

If the chloroform be pure (and that is a most important point), one of the effects said to be produced by it is completely avoided, and that is, the stage of excitement. I never now see any instance where excitement is caused by it in my own practice. There is no excitement, no bewilderment, and the effect at once is that of calm; but if the chloroform be not pure, you may be sure that the tumbling, and tossing, and delirium which have been ascribed to its employment, will be produced.

The longest time I have used it in labour was five hours, and the shortest time a quarter of an hour; and even to accomplish a quarter of an hour of relief towards the close of a labour is a great matter. The delight which a patient experiences at escaping from the severe sufferings which attend the last stage of labour, and having her child brought into the world without undergoing them, can be well imagined.

As I have already remarked, the manner of using the chloroform is different from what it is when we want to produce anæsthesia for surgical purposes. In the latter case we give it as rapidly as the case will permit, so as to produce an immediate effect on the constitution. The reverse, however, is true in midwifery practice; for there it should be given very gradually, and increased in proportion as the sufferings of the patient increase; and therefore I think the apparatus should not be the same in midwifery as in surgical practice. In the paper which I published two years ago, I stated that I preferred the handkerchief for the purpose of applying the chloroform, and that was the opinion which I then entertained. Immedi-

ately after the appearance of that communication, I had a letter from Dr. Murphy of the London University, commenting on my paper, and at the same time suggesting that an instrument which he was in the habit of using, and which he sent me, would answer the purpose much better than a handkerchief. Dr. Murphy stated the reasons for his preference of this instrument, which appeared to be very satisfactory; and those reasons were, that when a handkerchief was used, the chloroform was necessarily diffused through the room; that you could not regulate the amount which the patient inhaled, as well as you could with the apparatus he sent; and that the waste of the chloroform is much greater. Dr. Murphy begged me to employ the instrument; I did so, and since that time I have constantly used it, and have had no reason to regret its employment. It was made by Coxeter, the instrument maker to the London University. For surgical purposes, nothing could be better than Dr. Fleming's apparatus; and those who have read the concise and explicit publication which emanated last year from his pen, must be familiar with it, and the mode of administering chloroform in surgical practice. But I would not like to allow so large an amount of vapour as escapes in his apparatus to be inhaled by a midwifery patient, because it is not necessary to give so much, and not being necessary, I think it would be improper to administer it.

The apparatus alluded to is evidently a modification of the instrument formerly used by Dr. Simpson for the administration of ether, and called by him the "ether flask;" a representation of which is given in the Transactions of the Obstetric Society of Edinburgh, session 1846–47, and from which it differs principally in being furnished with two valves on the upper surface; one opening inwards to admit atmospheric air into the mouth along with the vapour of chloroform, the other opening outwards to admit of free expiration. It consists of a small round chamber, about two inches in diameter and one inch deep, in which a piece of sponge is placed, and to which a conical mouthpiece is attached, just large enough to cover the mouth of the patient. The aperture by which the mouthpiece and chamber communicate is about three-fourths of an inch in diameter, and is stopped by a cork when the instrument is not in use; the opening by which the sponge is introduced into the chamber is on the upper surface, and is about an inch and a half in diameter, and is closed by a well-fitting cover, in which is the valve for the admission of atmospheric air. The manner of using is simple enough. After pouring a teaspoonful of chloroform on the sponge, previously moistened with water and well squeezed, the mouthpiece is loosely applied to the mouth of the patient, and she makes a few inspirations. By the nose being left uncovered, and by means of the valve in the cover, a large portion of air is admitted along with the vapour of chloroform, and thus it gains access to the lungs in a diluted state—a circumstance which I consider essential to the safe and satisfactory use of chloroform in midwifery practice.

If there is any difficulty in getting the patient to inhale properly, it is only necessary to lay hold of the nose, and tell her to suck the chloroform out of the tube, and she will very soon learn the proper way of doing it. By means of an apparatus of this kind, we can keep a patient for any length of time calm, tranquil, happy, and free from pain, no matter how protracted the labour may be, and without for one moment rendering her insensible.

The dose can be properly graduated with the instrument; we can put in as much as we like, and we can be certain that no more will be inhaled by the patient; whereas on the handkerchief she may inhale a great deal more than we wish her to get. In this way, one drachm will go as far as an ounce will go on a handkerchief. I was formerly in the habit of using an ounce of chloroform on a handkerchief in the space of one hour; I now seldom use more than a drachm of chloroform in the same time. The patient may hold the instrument herself, and this is a security in itself against an overdose; for if she becomes insensible she is no longer capable of holding it to her mouth, and cannot therefore inhale too much of the chloroform.

I have extracted the particulars of thirty-three cases in which I have used chloroform since the paper to which I have already referred was published, and I may just read an abstract from it. I find that—

Two of the patients had the chloroform for five hours (both first cases);
Two for four hours (one being a first case);
Three for three hours (two being first cases);
Four for two hours (three being first cases);
Four for an hour and a half (two being first cases);
Six for one hour (two being first cases);
Twelve for periods under half an hour.
Total thirty-three cases.

Of the foregoing cases—
One was of thirty hours' duration;
Three of twenty-four hours;
Three of twenty hours;
One of fifteen hours;
Eight of ten hours;
Fifteen of five hours; and
Six under five hours.

In the former paper alluded to, I advocated the using of ergot of rye, in conjunction with chloroform, in certain cases there specified.

As perhaps as good an example of the value of the combination of these medicines as could possibly be presented, I will mention the particulars of a case that occurred since this day fortnight, when I was prepared to lay these observations before the Society. Since that time, in fact within the last week, I attended a lady whom I had delivered on some former occasions, and who had several children before she became my patient; and, as we sometimes perceive, it happened with this lady that the great majority of her labours were of a preternatural character. She had shoulder-presentations four times, a couple of breech-presentations, and several premature children of four and five months. Upon the present occasion her labour commenced early in the morning, about three o'clock, and the pains were exceedingly weak for twelve hours afterwards, at which time I was sent for, and on my arrival I found an arm presenting at the os uteri, which was then dilated to the size of a half-crown piece, and very soft, with the membranes still unbroken; but the uterine pains were very weak and unfrequent. She had already experienced the torture of turning too often not to dread a repetition of the process; and she had made up her mind that if it was a cross-birth she would have chloroform administered, as she could not venture to face turning again without it, several of her friends who had used chloroform having told her of the advantages to be derived from its employment. At the labour which preceded the one of which I am now speaking, she was near dying from hæmorrhage; indeed I do not think I ever saw a patient run so near to death and not die as this lady did on that occasion, owing to the complete inertness of the uterus, and its inability to contract. Here, then, was a case of arm-presentation, an inert uterus, a lady calling for chloroform, and turning absolutely necessary. What was to be done? I was confident that if I turned the child under the existing circumstances, and emptied the uterus, which was so little disposed to contract, I would run a risk of producing a hæmorrhage as terrific as that which followed her previous labour. I therefore commenced by giving a dose of the ergot of rye, and I watched its effects. As soon as the pains became in the least degree quickened, I commenced the use of the chloroform. She inhaled it for two minutes, and then I passed in my hand, ruptured the membranes, and got the child turned. The whole operation did not last ten minutes; scarcely a drop of blood was lost, and when it was over, she told me that she would not care again about having a child to be turned, provided she suffered no more than she did on that occasion. I mention this case as a good instance of the great value of the combination of the two agents. Now let me impress upon the Society the importance of only using chloroform which is genuine and pure; for I consider it, when properly prepared and judi-

ciously used, as one of the greatest blessings which has ever been introduced into the practice of midwifery. I get mine at Butler's Medical Hall, where it is prepared by Mr. Morley, his chemist. I do not say that it is not well made elsewhere, but I know that what I have obtained there is of the very best and purest quality, and has never produced the slightest degree of excitement in any of my patients; but on the contrary, the greatest tranquillity and comfort. I would urge upon persons engaged in midwifery practice not to allow themselves to be foolishly deterred by the nonsense of those who talk of after-consequences, and say that patients who have had chloroform are likely to suffer from disease of the lungs and brain after its administration. This is all absurd. The moment you remove the apparatus, the effect of the agent is gone, and the patient is perfectly free from its effects: but there is, I fear, one reason which has interfered with its introduction into practice—namely, that it involves a good deal of trouble; for the man who uses chloroform must stay by the patient's bedside and watch its effects upon her. This, I am afraid, is one cause why gentlemen are not so anxious to use chloroform as they ought to be; but it is a very bad one, and any man who takes charge of a woman in labour, should recollect that it is his duty to get her through it as quickly and with as little suffering as he possibly can, consistent with her safety. I am quite sure that any man who, as I have done, experiences the gratitude which women express with whom it has been employed, will never lose an opportunity of using an agent which he has found so exceedingly useful.

As I said in my former communication, it requires to be *studied* in order to its proper and safe use; but in judicious hands, it is one of the greatest blessings conferred upon suffering humanity. Its discovery will immortalize the name of Simpson, which will be handed down as that of a benefactor to science on the same page as that of Jenner.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

INVERSION OF THE UTERUS AFTER PARTURITION PROVING FATAL IN EIGHTEEN MONTHS.

By J. G. Forbes, Esq.

The patient, a lady, aged 25, came under the care of Dr. Robert Lee, and the author, in December, 1850, being in appearance intensely anæmic, and suffering from the usual symptoms attendant upon this state, as well as from periodical attacks of profuse uterine hæmorrhage. On examination per vagina, a tumour of a pyramidal shape was detected projecting for about two inches through the os uteri, with which it appeared in close connexion throughout its entire circumference. Her confinement had taken place in the country in April of the same year, and an account of it was furnished to the author by her medical attendants. Owing to the cessation of pain, ergot was administered, the os being fully dilated; and a loop of the cord having descended in advance of the head, the forceps were employed to complete the delivery. The infant was still-born. Nothing unusual was apprehended until several days after the labour, when the patient stated that during the action of the bowels on the third day "something had come down." It was now discovered that the uterus was inverted, having descended to within an inch or two of the labia. Re-inversion was found to be impracticable. Slight sanguineous discharge continued up to the 12th of July, on which day profuse hæmorrhage took place. This recurred afterwards at each catamenial period, the discharge being often of a serous character, and was accompanied with hysteria, headache, vomiting, constipation, and great exhaustion. On the 18th of December, Dr. Locock was called in consultation, and the propriety of applying a ligature around the tumour for the purpose of extirpating it was discussed, but owing to the diminution of hæmorrhage at that time it was not done. The pain produced by pressure on the tumour, precluded all hope of accomplishing its reduction. The treatment adopted was therefore only palliative. In April, 1851, the patient returned to the country, when, after the lapse of some months, her health began to improve. The hæmorrhage also ceased, for the last three catamenial periods of her life were passed over with only a moderate amount of discharge. The period which commenced early in November was attended with intense headache, which, in spite of remedies, increased; erysipelatous redness of one side of the head and neck came on, and the patient gradually passed into a state of coma, under which she sank and died on the 10th inst. A post-mortem examination disclosed incomplete inversion of the uterus, the tumour not being constricted by the os. The left ovary was enlarged, and contained a cyst filled with sanguineous fluid. The paper then contained some remarks on the question of attempting the extirpation of the inverted uterus in such cases by operation, a few observations being made, first on those cases in which no operative proceeding was resorted to, and then upon the several modes of operating which have been practised, and their results. Some cases, it was stated, underwent spontaneous re-inversion, and in others the vitality of the tumour was destroyed by inflammation or by the constriction of the os uteri, and the patients recovered. The difficulty in accomplishing the reduction of the uterus after the lapse of a few hours, was then spoken of, and a few cases were quoted in which in was effected at later periods. The duration of life under inversion of the uterus was then considered, and Mr. Crosse's statistics were referred to. Cases in which extirpation of the uterus was performed by excision, a ligature alone, and by both combined, were next quoted, and a summary was given of the table appended to the paper. In the latter, which contained brief details of thirty-three cases, collected from different sources, it appeared that nineteen were successfully treated by ligature, and five unsuccessfully (three died); one successfully and two unsuccessfully by excision; and five successfully and one unsuccessfully by ligature and excision combined. The paper was concluded by a general statement of the treatment pursued in the case detailed.

After a pause,

Mr. Hodgson rose, and said that he trusted a paper of so much importance would be discussed. Some years since he had seen a patient somewhat in the condition described in Mr. Forbes's case; but the inversion was more complete, the parts presenting externally in the shape of a small pyriform tumour, from which there was continual bleeding, increased at the catamenial periods. He recommended its removal, but the patient would not consent, and died twelve months afterwards, of consumption. When this case had occurred to him, he had found great difficulty in procuring any definite information as to the mode of treatment by referring to books. Had such a table as that appended to Mr. Forbes's paper existed at the time, it would have saved him much trouble, and he should have treated the case with more confidence. But the only information he could procure at that time was scattered over various works, Mr. Crosse's book not having yet been published.

Mr. Arnott could give but little information on the subject of the disease; these displacements were rare, but it was desirable that the personal experience of members should be stated. This, indeed, was the chief object of their assembling to hear a paper. He had seen two cases of inversion of the uterus, but these would not enable him to speak decidedly on the more important point in Mr. Forbes's paper—viz., the propriety or non-propriety of interference by operation in these cases. He trusted that other Fellows of the Society would communicate their experience upon this matter. Three years since, he was consulted on a case, which was supposed to be a polypus of the uterus by a distinguished accoucheur who suggested its removal. Two other gentlemen had also been consulted: one pronounced the case to be polypus, the other suspected it to be inversion of the womb. With this latter opinion he (Mr. Arnott) agreed. The history of the case was simple:—The woman was aged 27, and had been confined twelve months previously. There was some tugging at the navel string, but after three tugs it came away. There was not excessive hæmorrhage at the time, but more or less bleeding continued for four months, at the end of which

time an examination was made, none having been instituted before; and then a difference of opinion existed as to the presence of a growth, or of inversion of the uterus. A ligature, however, was applied, and the bleeding ceased. The woman did not get well, suffered much at the menstrual period, and on laughing or making any exertion, something protruded from the vagina. She now came to London, and he (Mr. Arnott) saw her under the circumstances above mentioned. On the first examination, the tumour had every appearance of a polypus of about the size of a goose's egg, firm, with a pedicle. There was an offensive discharge, not menstrual, which had continued for seven weeks, but there was little difference in the sensibility of the part. He doubted if it was a polypus, but thought it might be so. He felt the pedicle encircled by the os uteri. The surface was livid at some portions, and tender at one part. This was not sufficient to determine that it was not a polypus. Another opinion was now sought in the case, and the accoucheur called in pronounced it to be a polypus. It was now determined that the patient should be placed under chloroform, the tumour brought down, and if a polypus, that it should be removed. When brought down, the tumour exactly resembled a polypus, and on passing the finger into the bowel, what was supposed to be the uterus could be distinctly felt in the rectum. Mr. Arnott, however, was determined to act with caution, and therefore made an incision into the pedicle, when it was at once detected to be an inverted uterus. A ligature was applied, but as hæmorrhage continued below its seat, another, and even a third, was used before the bleeding ceased. The parts were then returned. The woman died of peritonitis. This case showed the necessity of caution in our diagnosis of these cases, and the difficulty there was of restraining hæmorrhage. Now, what was the tumour felt through the rectum when the tumour was down? This was no doubt the bulging out of the neck of the uterus, as if it were the whole body of that organ. This case constituted his sole experience of these cases. Before the occurrence of the one he had just related, he had considered that the best mode of proceeding was to tighten the ligature at once, but now he thought the employment of a metallic ligature preferable, which should be slowly tightened. Experience, however, was wanted on this point. It was not easy to procure adhesion in these cases, and hence it had been thought better to tighten the ligature at once. He had seen another case in which there was copious bleeding, and an operation was suggested; the patient would not consent, and died worn out.

Dr. Murphy made some remarks on the difficulty of diagnosis in these cases, and mentioned an instance related by Velpeau, in which a polypus was mistaken for inverted uterus. The accident was usually the result of want of attention in the first instance, and never occurred in the hospitals of Dublin and the continent, where great care was employed. In the case recorded, there was some obscurity as to the progress of the last labour and the cause of the displacement. He related a case recorded by Mr. Crosse, and occurring in the practice of Mr. Martineau, at Norwich, to show that, by early and judicious treatment, the displacement might be remedied. In this instance a lady, whose labours were remarkably rapid, was seized with a violent pain whilst standing up, by which the child was expelled. She had severe pains afterwards, and on a careful examination being instituted the uterus was found to be partially inverted, and was replaced, If the uterus became quite inverted it was most difficult to replace it from the great contraction which existed. Much mischief might ensue from persevering attempts to reduce the displacement. It was mentioned, in some cases, that the uterus had gradually restored itself to its right position, but he (Dr. Murphy) believed that, in these cases, it was simply a reduction in the size of the tumour, and not a replacement. If the first few hours passed after the accident, and the uterus was not restored, it was impossible to replace it by mechanical means. Then the question presented itself, is it desirable to remove the uterus, or to leave the case to Nature? On this point it was a mere balance of the chances of life. He could not help thinking, however, that with further improvements in surgery the organ would be removed as easily as any other. Dr. Johnson of Dublin had operated twice or thrice successfully. He employed silver ligatures.

Dr. William Merriman related the case of a lady who had been attended by his father for supposed polypus of the uterus, but which turned out to be inversion of that organ. The patient was operated upon by ligature, but died. The chances of life were about equal when an operation was performed, as when it was not. He inquired if any attempts had been made to reduce the inversion in Mr. Forbes's case, whilst the patient was under chloroform.

Mr. Barlow recollected a case which occurred in his father's practice, of a patient who had extensive inversion of the uterus, and which was replaced.

Dr. Tyler Smith was sorry to hear Dr. Murphy attribute the occurrence of inversion in all cases to some fault on the part of the medical attendant. He was convinced it might occur without any negligence or interference on the part of the accoucheur to account for it. The uterus had been known to invert itself suddenly after labour, when the woman was lying perfectly still; it had also happened in women who had not been recently delivered; and there were cases on record in which even the virgin uterus had inverted itself spontaneously. An opinion very generally obtained that the uterus is always inverted mechanically by injudicious tugging at the funis, but in this he could not concur. On the contrary, he considered that inversion was usually a muscular act of the uterus itself, similar to the action of the intestine which caused intussusception. He would suggest the use of chloroform in recent cases of inversion, from its power of diminishing uterine contraction, and from having had cases of prolonged retention of the placenta, with spasmodic contraction of the os and cervix uteri, yielding to no other means, which had been overcome by the use of chloroform. It was melancholy to reflect that a mal-position so slight as that which existed in the preparation upon the table of the Society, should cause almost inevitable death. While listening to the details, it occurred to him whether chloroform would have been serviceable had it been resorted to, when the reduction of the inversion was attempted, with a view to allaying the pain and relaxing the tissues, as had been done in strangulated hernia while applying the taxis. In veterinary practice, inversion of the cornua of the uterus was not an uncommon accident, and recently an instrument had been used, consisting of a ball affixed to a rod, for the purpose of reducing the displacement, and, as it was said, with great success. Some modification of this might probably be of use in obstetric practice, as such an instrument would give the practitioner more command over the uterus than could be exerted by the hand alone.

A long pause having ensued,

Mr. Hodgson said that he regretted that the interesting case of Mr. Forbes had not given rise to more discussion, particularly as so many experienced accoucheurs were present. In the case which he (Mr. Hodgson) had detailed, the appearances were not likely to lead to a mistake as to the nature of the tumour. It would seem that the operation of removal might be attempted in young persons, but the proceeding was not so justifiable later in life, as the patient became more tolerant of the disease, and the hæmorrhage became gradually lessened. Not only was the operation justifiable in early life, but it would appear to be desirable, as in all cases the patients died when the disease was left alone.

Dr. Locock observed, that cases of inversion of the uterus were very rare, and that it was nearly impossible for any one person to have seen a sufficient number of cases to warrant him drawing any general conclusions, as to treatment, from them. It was necessary, to obtain such a result, to combine the experience of others with one's own. Some points of the discussion were of much interest. First, as to the replacement of the inverted uterus after delivery, and with reference to the time at which it could be effected. In one instance which he had seen, the uterus had been

inverted nearly three days before the accident was discovered. It was still very bulky. Efforts were made to replace it, but failed, great pain and vomiting being brought on; and it was feared there might be risk of rupturing the upper part of the vagina itself, so strong were the efforts required to be made. Three or four days afterwards, the attempt was renewed, but entirely failed, the parts having become so much contracted. If chloroform were to be resorted to in such a case, it must be employed very soon after the accident, because, when the inversion had existed any length of time, the inverted organ was no longer elastic or spasmodically contracted, but became perfectly solid, and it was nearly impossible to replace it without great danger of rupturing the vagina. To be successful, the effort should be made soon after delivery. In one case he had succeeded in replacing it an hour or an hour and a half after the accident. In proof that the uterus may be inverted spontaneously, he related a case in which the woman had no one near her, and there had been no pulling at the cord. The child lay in the bed, and the umbilical cord was not separated. The uterus, however, was completely inverted. He detached the placenta from the then convex surface of the uterus, which he had no difficulty in replacing. The patient did well. He recollected a lamentable case which had occurred to him about sixteen years ago. He was called, and found two medical men attempting to bring away what they supposed to be the placenta, but which was in reality an inverted uterus. The patient died before he arrived, and all he could do, to save appearances, was to remove the placenta and replace the womb. He had seen five cases of inversion of the uterus; of these, four were preceded by attempts to remove the placenta by pulling at the cord, and the fifth was the one he referred to as occurring spontaneously, and which he succeeded in replacing. The uterus would also now and then become inverted in consequence of the presence of a polypus. Such a case was related by the late Dr. Hooper. The preparation was, or ought to be, in the museum of St. Thomas's Hospital. In this case the uterus was partially inverted, from the expulsive efforts caused by a polypus little bigger than a small cherry. It could not have been the weight of the polypus, but the irritation produced by it, which caused the inversion. The woman died of uterine hæmorrhage. These were all the particulars of the case with which he was acquainted; the case had occurred in the St. Marylebone Infirmary. He (Dr. L.) had seen small polypi produce efforts of expulsion similar to those of labour. In one case he had found, on passing the finger, the uterus to be partially inverted from this cause. On removing the polypus the uterus became replaced suddenly, as if with a spring. He thought, with respect to the removal of the uterus in case of chronic inversion, there was much room to doubt its propriety; patients died of anæmia in these cases sometimes, as in Mr. Forbes's cases, and not from the inversion of the uterus alone. The case related by Mr. Arnott was unfavourable for operative procedure. There had been much manipulation before the application of the ligature; there was pain, and the surface of the inverted uterus was coated over by a thick layer of half-purulent lymph of an unhealthy character. The patient herself was not healthy. This therefore was not a fair case to arrive at a decision upon. When, however, we found so many patients lived in comparative comfort after the cessation of menstruation, that so much could be done with styptics and other local measures, as well as by constitutional treatment, an operation should not be lightly resorted to. As to the operation itself, nothing could be easier; and he could not see, with Dr. Murphy, how improvements in surgery could make it safer. The fear was from the peritoneum being involved in it.

Dr. W. Merriman inquired, if in the case of three days' standing, the chloroform, if employed, might not have been successful?

Dr. Locock replied, that his observations applied more particularly to cases of chronic inversion of the uterus. If chloroform had been used in the case he had referred to, it would have prevented the expression of pain, and hence there would have been fear of mischief being done.

Dr. Murphy said, that in his remarks regarding the improvements in surgery influencing the operation, he alluded to the kind of ligature to be used, the period of operation, &c. &c.

Dr. Snow said, that chloroform would undoubtedly be of the greatest advantage in facilitating the reduction of the inverted uterus, by the complete relaxation of the muscular contractility it would cause, in any case that had not existed so long as to be altogether beyond the reach of aid. The pain of the operation would also be prevented; but he could not concur in the objection of Dr. Locock, that the operator would be liable to rupture the vagina by the force he might use, for his own sensations would be a much better guide as to the amount of force he was using, than the cries of the patient. In this, as in other cases, he considered the opinion that an operator required the sensations of his patient to guide him, was erroneous. Many surgeons objected, at first, to the use of anæsthetics in lithotrity, for fear that they should seize the coats of the bladder in the instrument, without knowing it; but the fact was, that if the surgeon were liable to grasp the coats of the bladder, and then to be warned of it by the cries of the patient, the operation would not be safe under any circumstances. These objections were giving way, and chloroform was coming into general use in lithotrity, with the best effects.

Mr. Charles Hawkins remarked, that there was not the slightest fear of seizing the coats of the bladder in the operation for lithotrity; indeed, it was difficult to do so. Chloroform was not recommended, because it was desirable to know how long the patient would bear the operation.

Mr. Quain said, that according to the experience of obstetricians, chloroform did not interfere with the contractions of the uterus; as it only relieved pain, how could it be useful in reducing the inversion of the uterus?

Dr. Snow said, that nothing was better ascertained than the fact that a full dose of chloroform always completely suspended uterine contraction, however strong it might be; and he had seen cases where the child was turned in utero, with the utmost ease, under chloroform, when just before the contractions had been very powerful. He said that he could refer Mr. Hawkins to many passages in print, where the objections that he had mentioned were made respecting the use of chloroform in lithotrity.—*Lancet.*

PHARMACEUTICAL SOCIETY.

Mr. Scanlan laid before the meeting a specimen of carbonate of ammonia, presenting some points of interest. It had been obtained as one of the products of the ordinary process for the preparation of sesquicarbonate of ammonia, and it differed from that salt in being devoid of any pungent smell. It was crystalline, transparent, and permanent, when exposed to the air. It formed the lowest portion of the sublimed cake of ammonia, the upper portions, consisting, as usual, of sesquicarbonate of ammonia. He had submitted some of the specimen to analysis, and obtained the following results:—

Ammonia	21.52
Carbonic acid	55.69
Water	22.79

A similar compound was noticed some years ago by the late Mr. Richard Phillips, in the Annals of Philosophy, New Series, vol. i., for 1821, as having been received from Dr. Henry of Manchester, who obtained it in a process adopted for making common smelling salt. Mr. Phillips had analysed it, and got the following results:—

Ammonia	21.16
Carbonic acid	55 50
Water	23 34

ON THE BASIS OF THE EAU MEDICINALE D'HUSSON.

By T. Bushell, Esq.

The subject which I am about to bring under the notice of the Pharmaceutical Society relates to the history of a

very powerful article of the materia medica, the "Eau Medicinale D'Husson," which, although now obsolete, is still frequently referred to as the form in which colchicum was first introduced into medical practice; and I trust, I shall be excused for occupying the attention of the meeting for a few minutes in relating some circumstances contributing to establish the identity of the *Colchicum Autumnale* as the basis of that remedy which enjoyed so great a repute about half a century ago as a proprietary specific for the treatment of gout and rheumatism.

A few days since I made inquiry of one of the chief vendors of patent medicines, at the west end of the town, if they now sold the Eau Medicinale; I was informed that it had not been inquired for for many years, but that they had been accustomed, when it was in demand, to receive it from a foreign perfumer in Bond street. I then called at this house, and was politely informed that they were the proprietors and vendors of the Eau Medicinale D'Husson, but that they had not sold any for years, and that it had gone quite out of date. About four or five years ago they sold three or four bottles. I requested to be allowed to examine the remedy, and to see in what way it was sold or made up. After a little time two or three bottles were discovered; they held about two drachms, and were simply labelled "Eau Medicinale D'Husson." Printed wrappers, descriptive of its powers, were not at hand, and the parties seemed to have quite forgotten the doses in which it was administered. They informed me that the price was now nine shillings and sixpence, but was originally twenty-two shillings. The bottles were short and squat, quite curiosities in their way, and I could not resist revolving in my mind the great alteration which time and circumstances had made in the repute and consequent sale of this remedy, which at one time must have realized a splendid income to its proprietor.

The earliest medical notice I can find of the Eau Medicinale, is by Dr. Jones, in the year 1810, who had been on the continent in the years 1802 and 1803, with a gentleman who was a great sufferer from gout, and had then heard of the remedy of Husson, and which, on his return home in the year 1805, he was induced to make use of. He derived so much benefit from it, that from this time it made great advances as a remedy in England, and to quote the words of the editor of the *Edinburgh Medical and Surgical Journal*, "noblemen and philosophers concurred in sounding its praises, if not in dancing hornpipes, in testimony of the new agility and flexibility of toe with which it had endowed them; and the President of the Royal Society, Sir Joseph Banks, who experienced the most extraordinary deliverance from his arch enemy, is said to have made it almost his pocket companion." It now became a great desideratum to ascertain its composition. Rhododendron chrysanthemum, digitalis purpurea and lutea, tobacco, elaterium with opium, and many other plants, supposed to be analogous in their action to the magic water, were stated to form its basis.

Dr. Pereira states in his Materia Medica, "The circumstances which have led to the extensive employment of colchicum in gout, are the following: About seventy years ago, M. Husson, a military officer in the service of the King of France, discovered, as he informs us, a plant possessed of extraordinary virtues in the cure of various diseases. From this plant he prepared a remedy called Eau Medicinale, which acquired great celebrity for abating the pain, and cutting short the paroxysm of gout. Various attempts were made to discover the nature of its active principle. In 1782, Messrs. Cadet and Parmentier declared that it contained no metallic or mineral substance, and that it was a vinous infusion of some bitter plant or plants. Alyon asserted that it was prepared with gratiola; Mr. Moore that it was a vinous infusion of white helebore with laudanum; Mr. Want that it was a vinous infusion of colchicum. Although most writers have adopted Mr. Want's opinion, we should bear in mind that the proofs hitherto offered of its correctness—viz., analogy of effect, cannot be admitted to be conclusive, as is well shown by the fact that they have been advanced in favour of the identity of other medicines with the Eau Medicinale."

I should apologise for making so long an extract from Dr. Pereira's work, but as it contains a perfect epitome of all that I have ever seen on the subject of the so-called gout specific, and as it leaves the question of the identity of its basis open to further inquiry, I hope that the circumstantial evidence which I now propose to lay before the Society, may somewhat clear up the point.

Mr. Want published his opinion in the *Medical and Physical Journal*, vol. xxxii., in the year 1814; and it was two or three years after that time, at the commencement of my apprenticeship, I was directed to prepare a preparation of colchicum in rum (four ounces of the dried cormus to a pint). I was residing close to Covent garden Market, and frequently had conversations on plants, &c. &c., with the late Mr. Grimley, the herbalist, to whom I applied for the colchicum. Mr. Grimley inquired of me if I knew how it was that the use of this remedy was discovered by Mr. Want? He then related the following circumstance:—Mr. Want had returned home from visiting patients, and met his wife on the stairs, and told her that her father had been seized with a violent attack of gout. The nursemaid, who was standing by, stated that she once lived with a little French gentleman, who prepared a secret remedy for the cure of gout, the Eau Medicinale; that he was accustomed to carry on his operations at the upper part of the house; and that there was a door on the staircase which he always kept locked, but that she had managed to obtain a little bit of one of the articles he made use of, and that she then had it by her locked up in her box. Mr. W. had not much difficulty in gaining a sight of this treasure. It was unknown to him, but he at once proceeded to Covent-garden Market, and applied to my informant, Mr. Grimley, to ascertain if he could recognize the portion of bulb. Mr. G. pronounced it to be the colchicum; and, to Mr. Want's further inquiry, informed him, that the only person who ever applied to them for it was a little Frenchman, and that he was accustomed to order from a cwt. to a cwt. and a half more than once in the season; that he adopted great precaution to prevent their obtaining a knowledge of what he did with it and from whence he came; that he always made inquiry if they had it ready, paid the amount charged, then brought a porter, who carried it to a hackney-coach which he had in waiting, and which immediately drove off with its precious charge—for precious it was, only to be compared to a lump of the Californian or Australian mineral, as its preparation sold for its weight in gold (two drachms twenty-two shillings). This relation, although occurring about three or four and thirty years ago, is quite fresh in my memory. I have related it to many, and about seven years ago I was in attendance on the late Earl Thanet, who suffered much from gout, and had a great objection to take colchicum. I happened to mention this little history, when he said, "You are quite right." I met that little Frenchman repeatedly years ago at the late Duke of Queensberry's, who was a martyr to gout, and to whom he used to administer the Eau Medicinale, he being the preparer of it. In the course of inquiry I have also found good reason to suppose that this little Frenchman was a well-known foreign perfumer, and has been dead upwards of twenty years, the founder of the house who now profess to be the proprietors of this once celebrated remedy.

I have stated that it was in the thirty-second volume of the *Medical and Physical Journal*, that Mr. Want first made public his discovery of the basis of the Eau Medicinale D'Husson, but I find on further reference that it was not in a medical but in a popular journal, the *Monthly*, that he had previously announced it. I should take up too much of the time of the Society, if I entered into the controversies which took place at this period, with respect to the reliance which could be placed upon this beyond the numerous other drugs which had been as confidently declared to form its active ingredient, and it was the opinion of many that ere long it would be consigned to the tomb

of the Capulets. I find, also, that a charge was made against Mr. Want, by an anonymous correspondent, that he had gained a knowledge of its basis by means somewhat similar to what I have now related, but which he denied, stating that he had obtained the first hint from Alexander of Tralles, who recommended a remedy, "Hermodactylon," for the cure of gout, and with the effects of which the Colchicum Autumnale entirely corresponded, and that this plant had entered into many gout remedies that had become obsolete. All I am now desirous to say on this subject is, that the blue chamber being once penetrated, its mysteries might be readily compared with those which had preceded, but I believe the key was obtained in the manner I have related to the Society.

The present holders of the recipe for the Eau Medicinale, were so ignorant of its powers, as to inform me that two or three drops were a dose. I find that the usual dose was half a bottle, to be repeated, if the effect was not apparent, in four or six hours, but it was not uncommon for parties accustomed to its use, to take the whole two drachms, and repeated cases are on record of its powerful and dangerous effects; even life in some instances fell a sacrifice to its imprudent exhibition; and such was the experience also with the Colchicum Autumnale when first brought into practice, as it was considered to be a specific, and administered accordingly. This is not the place for entering into the therapeutical action of this valuable and potent plant, but its botanical and chemical characters are highly deserving the attention of the members, and, combined with its pharmaceutical preparations, might form matter for most interesting discussion.

There is a galenical compound in one of the French codexes called Eau Colchique D'Husson, prepared as follows:—Dry colchicum, 60; sherry, 125; twenty drops in a glass of *eau sucrée* in gout and rheumatism; and there is a remark that this will be observed to differ from the tincture or anti-gout drops of Want, which has been given as the Eau Medicinale. Mr. Want's first recommendation was four ounces of the fresh root sliced to half a pint of proof spirit.

Before I conclude, I must direct your attention to the observations of Dr. Maclagan, lately published in the *Monthly Journal of Medical Science*, Edinburgh, and from which your own valuable journal of this month has an extract. I observe that Dr. Maclagan states that the flowers of colchicum are supposed to be the part of the plant used in the preparation of the Eau Medicinale.—*Phar. Jour.*

ORIGINAL COMMUNICATIONS.

ON A CASE OF PARAPLEGIA RESISTING OTHER TREATMENT CURED BY ERGOT OF RYE.

By R. D. White, L.R.C.S.I.,
Medical Attendant to the Askeaton Dispensary District.

TO THE EDITOR OF THE MEDICAL PRESS.

Dear Sir,—I enclose you the particulars of a case, for the favourable issue of which I am indebted to information derived from your journal. If you deem it worthy of insertion, I shall be glad to think my giving it further publicity, by the details of this case, may be accepted as some acknowledgment for the service the information has been to me and my patient.

I have not trespassed on your space by a daily report of the progress of the case, but given the substance from my notes, with as much brevity as was consistent with accuracy; nor will I do so by making any lengthened remarks upon it, such cases being unfortunately so common that almost every practical man has met with similar. But I think it worthy of particular notice, the state of the bowels in conjunction with the effect of the ergot upon them, and to suggest that the view some pathologists have taken of a class of cases called "obstruction of the bowels" is correct; which view is that these are cases of paralysis of the muscular fibres of the intestine. For I presume it will be admitted that the ergot of rye acted in this case by stimulating that fibre; which opinion, if established by further employment in similar cases of this agent, will be a very important step in the treatment of these hitherto very trying and generally fatal cases.—I am, dear sir, very faithfully yours,

R. D. White, L.R.C.S.I., &c.

Thomas Reedy, a farmer of small means, aged 50, consulted me early last December, and gave me the following history of his case:—About two months previous, having occasion to be out at night watching cattle, he was much exposed to cold and damp; he frequently sat for some time on wet banks and ditches, by which he thinks he got cold, for he began to feel what he in the Irish language calls a "druroch," which appears to be the sensation of numbness and pricking in the extremities, with which we are familiar as being a premonition of paralysis. This was felt in the lower extremities, and an increasing weakness in his back, loins, and legs, referred especially to his hips. He got worse from day to day (being under no treatment), until he lost entirely the power of progression, or assuming the erect posture; but when sitting down, he could move his legs about on the floor. There was no loss of sensation in any of the parts; his bowels were very obstinate, and never moved without active purgatives; appetite bad; he spent restless nights; little sleep, and that disturbed by troubled dreams; profuse perspirations, and his wife said he occasionally talked silly.

I first treated this case by blisters along the course of the spinal column, particularly the lower portion. I produced mercurial action by means of pil. hydrarg., in combination with sulph. quinæ and ext. tarax., in about a week. This object being accomplished, the pil. hydrarg. was diminished in quantity, and the effect kept up in a moderate degree for another week; occasional purgatives of an active kind were given.

A decided improvement was the result. To follow up the good effect, I established a seton over the sacrum, and continued the tonic treatment, aided by frequent frictions over the affected limbs, with stimulant applications, and the daily use of the flesh-brush.

By the early part of January, the patient could rise off his seat, and walk several steps, but not without the help of two sticks, and then with a very tottering gait. Appetite and sleep not improved.

Here the improvement ceased. I then had recourse to the exhibition of strychnine in pills thrice daily, and quinine in solution twice daily. Another slight improvement was the result, so the treatment was persevered in for about a month, towards the close of which his symptoms again disimproved; his strength began to fail; his appetite (which improved under the quinine, and was met with nutritious diet) gave way; his bowels became so torpid that the most active purgatives were necessary daily, for he complained of great distension, and consequent distress, if the bowels were not acted upon; night sweats became profuse, and weakening, and there was again loss of power. Fearing the discharge from the seton might be too profuse, I allowed it to heal slowly; and observing a muddiness about his intellect, I applied a blister to the nape, which had a good effect. He, however, now kept his bed continually, and became very desponding; which, indeed, did I too, regarding his case as hopeless.

Just at this period (early in February) I had the good fortune to meet with at a neighbouring medical friend's house a copy of the Dublin Medical Press, and among the selections from foreign journals I saw an account of some cases of paralysis treated by M. Gérard of Marseilles (I think) with ergot of rye successfully. Too happy to find anything bearing on the subject, I lost no time in exhibiting to my patient the doses recommended—3ss. ter in die—which I made into an electuary with treacle, stopping all other medicines, and hopefully waited the result.

I was not disappointed. When two ounces had been taken (the quantity first supplied), Reedy's wife came, according to directions to the dispensary, to report progress, and said there was no improvement, *except that the bowels*

had acted naturally for the last few days. I confidently assured her this was an earnest of improvement, and re-supplied the electuary.

On visiting him after this, I found him improved in every respect. The electuary was repeated, with the addition of ʒi. olei ricini, at the man's request, as he said from the time the bowels "came to," he felt himself getting better (this addition was, of course, only to please him). His improvement was now rapid, the power of motion returning to all the parts previously powerless; every unpleasant symptom vanished; so that by the first week in March—a month from the commencement of the exhibition of the ergot of rye—his recovery was complete, being able to walk up to my house from his own, nearly an English mile, *with his stick over his shoulder*, a performance he takes great pleasure in going through occasionally.

He now only complains of not being so strong as he was before his illness, and feeling "a little cowld pain" at times in his hips. I do not, however, anticipate a relapse.

LONDON HOSPITAL REPORTS.

GUY'S.

Puncture of the Bladder by the Rectum.

By Mr. Cock.

As opinions are very far from being agreed upon the propriety of puncturing the bladder through the rectum in cases of complete or partial retention of urine, when no instrument can be passed through the urethra, we are anxious to acquaint the profession with all the operations of this kind which are performed in the hospitals of London, whether the results be successful or otherwise. We must confess a great partiality for this operative measure, notwithstanding the possible accidents to which it can give rise. The latter, by moderate skill and attention, can certainly be avoided; and when puncturing through the rectum is compared with cutting into the perineum, and seeking for the urethra without any sort of guide, it becomes at once evident that the former operation is preferable, not only judging from the records of both, but likewise on purely theoretical grounds.

When it is considered that the urethra, which may have been exposed for months and years to the torture of straining and of the introduction of instruments, is suddenly thrown into a perfectly quiescent state, it may justly be inferred that this canal will, by this cessation of its natural functions, have time to recover itself, and be freed from the unavoidable congested state which difficult micturition and the frequent use of catheters or bougies must evidently produce.

We abstain from saying more just now, as we shall have ample opportunity of soon recurring to the subject. One remark only we shall add, touching the line of practice to be adopted in extravasation of urine, where little or none of that fluid is passing through the urethra. It is evident that when this canal has once been ruptured there is no more fear of retention; the urine finds an exit through the incisions, which are in such cases extensively made about the perineum, scrotum, and even penis, and the urethra is thus thrown into the same quiescent state which puncturing through the rectum generally affords. From these facts it might be gathered that such cases should be treated by the expectant method, the patient being of course kept up by the stimulants he may require. It would therefore be useful, in instances of this kind, to abstain from opening the urethra in the perineum or elsewhere, as that canal might perhaps, after a variable number of days, recover sufficiently, either to expel the urine in a tolerable stream, or allow the passage of an instrument. We now pass to Mr. Cock's case, as noted by Mr. Nason, one of the dressers.

S. L——, aged 43, married, and residing in the Borough, was admitted January 16, 1852, in the evening, under the care of Mr. Cock. The patient was suffering severe pain from retention of urine, and appeared in great distress. He stated that he had been subject to stricture of the urethra for the last ten years, after repeated attacks of gonorrhœa. Four years before admission he had retention for the first time, but was relieved by the catheter, and since that period has been obliged to have an instrument passed occasionally. He has observed blood from the urethra after each operation, owing to the difficulty with which the catheter was passed.

On admission, the bladder appeared very much distended, reaching nearly as high as the umbilicus, and the patient was suffering much. All attempts to pass an instrument into the bladder by the urethra having failed, the man was ordered one grain of opium and one of calomel, to be taken immediately.

On the next day the patient was somewhat relieved; he had perspired profusely during the night, and a small quantity of urine had escaped guttatim by the urethra. The catheter was again tried, but without success. Mr. Cock, therefore, punctured the bladder by the rectum with a trocar and canula, and drew off three pints of ammoniacal urine, much to the relief of the patient. The canula was then secured by the inner blunt-edged tubes being introduced within it, and the whole was left in the bladder.

The man went on well for the first week. The canula remained in the bladder, but the inner tubes were occasionally removed, cleaned, and re-introduced. On the twelfth day, the canula was removed, as he was suffering slightly from the irritation produced by its presence in the bladder. On the thirteenth day, the right testicle became inflamed and swollen, and a small abscess appeared in the perineum. Both these symptoms yielded easily to treatment, and were not at all connected with the urinary canal. Fourteenth day. The patient now passes a minute quantity of water by the urethra, but no instrument can be guided through the seat of stricture. Thirty-fifth day. A No. 1 catheter was introduced into his bladder for the first time since the operation, and was secured, the patient having passed nearly the whole of his urine by the artificial opening in the rectum for five weeks. Forty first day. The urethra is daily gradually dilated, and now a No. 5 elastic catheter can be passed without any difficulty. Since the introduction of a catheter into the bladder, not any of the urine has passed by the bowel. March 1st, being the forty-fourth day after admission, the patient is now well, and able to pass a good-sized stream of urine by the urethra, and the puncture in the rectum has entirely closed.—*Lancet.*

CASES OF SYNOVIAL ARTICULAR INFLAMMATION OF THE KNEE TREATED WITH URATE OF AMMONIA.

By W. E. Horner, M.D.,
Professor of Anatomy in the University of Pennsylvania.

The liniment of ammonia is so well known in the treatment of chronic articular affections, that its character may be considered as settled; but my attention has been only lately called to the still higher powers of urate of ammonia, an article which, though sufficiently offensive to the olfactories, has a strong compensating quality in the efficiency of its action. My first observation in regard to it was the result of having accidentally been called to a poor woman who was in a state of unremitted and excruciating suffering, day and night, but especially during the latter period, from a chronic inflammation of the knee-joint, attended with considerable swelling and tenderness, and some degree of redness. I made to it the ordinary applications of cold fomentations, and evaporating lotions, enjoined rest, attended to her diet and the state of her bowels, and gave opiates at night in the shape of Dover's powder. After ten or twelve days of attendance, in which no progress was made to a cure, I was gratified on a visit to find that the pain had ceased suddenly, and that the preceding night had been spent in great ease. The strong expression of satisfaction on my part, led to a communication from her, with many apologies for herself, that, finding the disease so little abated, she had been tempted to try the remedy of a simple friend, who had been remarkably improved by it in a similar attack. This remedy was a poultice made of

human urine, thickened with potter's clay, and put on as warm as one could bear it; and to be repeated when it got dry. She declared to me that this rather indelicate application had relieved her of all pain in a few hours. The fact of relief was incontestable; the question was in regard to the remedial agency of the article employed, and I therefore determined to make some experiments on the value of ammonia in combination with fine argillacious earth.

Having a similar case shortly afterwards, in the St. Joseph's Hospital, I tried in it a solution of muriate of ammonia formed into a poultice. No very distinct or satisfactory result followed, and it was discontinued. Having the idea still in my mind, and wishing to be satisfied about it, but reluctant to employ the article resorted to by the poor woman, I determined to find my urate of ammonia in some other form of an easy kind, and for that reason adopted the guano, which has so large a proportion of phosphate of lime, urea, and urate of ammonia in it. A female patient, aged 34, Mrs C., from Tamaqua in this State, who had for more than a year laboured under inflammation of the right knee, was put under my charge at the St. Joseph's Hospital, October 8, 1851. She had been well attended to by Dr. Scherner, who had conducted her through the most acute period of her complaint. The joint had suppurated, and she came to town with a small fistulous orifice on the inner side of the knee, through which a probe could be easily passed between the tibia and os femoris. From this there came daily a spoonful or more of matter, when a plug was withdrawn from the orifice. She still suffered great pain at night, the part was tender, and was in continual uneasiness, and she had some slight fever in the afternoon. Here was exactly the case to try the efficacy of urate of ammonia, as naturally formed in animals. I accordingly obtained some guano, and had it made into a hot poultice with clay. The joint was kept enveloped in the poultice with frequent changes for nearly the remainder of the month, at the end of which time a very marked improvement had taken place in the amount of pain, and also in the degree of swelling, and the purulent discharge had almost ceased.

The application produced a very copious vesication of the knee, and it had to be weakened to reduce the caustic qualities. Having conducted this treatment as far as seemed necessary, the skin was permitted to heal. Some little pain recurring afterwards, she was blistered for it; that getting well the emplastrum calefaciens was applied, and the leg was also kept supported by an extending band on the ankle, and a counter-extending one on the thigh, their action being sustained by a splint on the outside of the limb. At the end of six weeks (November 25th), she has left the hospital without pain or uneasiness in the knee. The joint is in a state of false anchylosis, and straight. I have covered the knee with emplastrum adhesivum, and secured it in that position with strong pasteboard splints, moulded to the knee, and have recommended her to keep it so for two or three months, until all danger of secondary suppuration be removed. Probably at the end of this time the judicious use of frictions and of Stromeyer's screw splint may impart some flexion to the limb.

The hospital record sheet shows the following details of dates, which may be inserted in this place:—October 9th. Poultice of guano (urate of ammonia) and potter's clay, equal parts. 10th. Poultice has blistered. It was discontinued, and simple cerate applied. 11th. Patient has less pain; soreness of knee reduced, and not so much swelling. A poultice with one-third of the urate of ammonia and two thirds potter's clay. 13th. Vesication. 14th. Quantity of urate reduced to one-fourth of poultice, treatment continued pretty much in this state to near the end of the month. Vesication by emplast. cantharid. about this time, but omitted on record. 28th. She was permitted to eat as she pleased.

November 5th. Emplastrum calefaciens. 12th. Discontinue emplastrum calefaciens, and re-apply the urate of ammonia as on the 14th of October.

While this case was in progress, another occurred in a boy who had the knee joint opened by a cut of half an inch or so in length. Synovial inflammation followed, with the ordinary symptoms. Its usual acute period was passed through, under the depletory antiphlogistic treatment, and with evaporating lotions to the part. The disposition to fall into the chronic state, attended with tumefaction, was relieved by five days' use of the same argillacious, uro-ammoniacal poultice. The ward sheet exhibits the following entries in regard to this case: Patient, Timothy Roach, aged 19, admitted September 23rd, a day or two after accident; knee painful and stiff, somewhat swollen; rest and fomentations of warm water directed on that day; also loss of ten ounces of blood from arm. 24th. Local bleeding by scarified cupping; fomentations continued.

October 4th. Warm fomentations to this date; in the meantime an evident articular effusion has occurred into the synovial membrane of the knee; a blister plaster, four inches by four, was then applied. 6th. Blister plaster two inches by three. 7th. The patient so much relieved from pain as to be permitted to leave his bed and promenade with a crutch. 9th. Some aching and tumefaction indicated a persistence of articular irritation. The poultice of urate of ammonia (guano) one-fourth, potter's clay three-fourths, was then applied hot, with frequent renewals to the 14th of October, at which time all the symptoms were relieved. The patient was discharged cured the 15th.

The above cases are reported much in outline. I shall continue, as opportunity offers, to test the value of the above remedy, and also compare its results with other remedies. It appears to me to have some special qualities, which are of a highly beneficial kind in the affections alluded to. It is so active a revulsive when applied strong, that I have no doubt of their being many cases of serous inflammation in which it may be usefully resorted to. I would here suggest a trial in puerperal peritonitis and in pleurisy. I see no objection except the odour. The poultice of guano and clay dries very quickly, so that it is better to shield it with oiled silk or India rubber cloth. The clay I look upon as simply a vehicle, but it may also have some physiological action from its physical properties in regard to moisture. The analysis of the best guano by the chemist presents the following constituents, which are mentioned here for facility of reference. The proportions will vary according to their atmospheric exposure and to the degree of adulteration in trade. As it is an expensive article for agricultural purposes, it has become common to reduce its chemical relations by the addition of common earthy substances:—Uric acid, thirty per cent; uric acid with ammonia; carbonate of ammonia; muriate, oxalate, and phosphate of ammonia; free ammonia; phosphate of soda; phosphate of lime; sulphate of potash and soda, and oxalate of lime. It is the large quantity of ammonia in it which makes it so active a stimulant to vegetable growth, and so disagreeable to the smell. It, however, is not so intolerable medically as assafœtida, an article which we have but little hesitation in prescribing.—*Phil. Med. Ex.*

ON THE VARIETIES OF ALVINE DISCHARGES IN CHILDREN.

By Dr. Merei.

The intestinal discharges mentioned by the author are:—

1. The *yellow* discharge. This is the regular kind of stool in infants. It is a mixture of intestinal secretions with bile. As children advance in age, and begin to take substantial food, the colour of their regular discharge becomes more and more of a light brown colour.

2. The *mucous* discharge. White mucous matter, more or less thick or liquid, and mixed with serum, sometimes with a proportion of bile. This discharge is preceded by but moderate pains, and frequently by no pains at all. It denotes a catarrhous, sub inflammatory, or irritable state of the intestines, and is almost always of local, and not of sympathetic, origin; in general it is not dangerous, and at its commencement is easily manageable by opiates, warm poultices, and convenient hygiene. If neglected, it becomes pertinacious and severe, and not seldom connected

with swelling, softening, or granules of the mucous membrane, or ulceration of the follicles. If stripes of blood are mixed with the mucus, and pain be present, it denotes a higher degree of inflammation, in particular of the follicles. The highest development in this direction constitutes enteritis or colitis (dysentery).

Sometimes we find among the mucus, consistent *plastic concretions* of a more or less tubular shape, similar to those of laryngeal croup, but larger in proportion to the volume of the intestines. This is the strongest degree of the catarrhous process, which I might term the *croup of the intestines*. Among the whole number of my little patients, which may be about 30,000, I met with this discharge perhaps only twenty or thirty times. The discharge is effected with very painful efforts at a stool.

3. The *serous*. In general, after more or less severe pains, the discharge takes place with a certain rigidity and noise, after which the pains lessen or subside. It consists of an abundant quantity of serous liquid, dirty-whitish, yellowish, or greenish, as besides mucus, bile is the most common mixture with the serum. The serous diarrhœa is commonly the effect of rheumatism in the peritoneum, in the serous and fibrous membranes, or in the nerves of the intestines. I found in these cases the abdomen very hot. If a great deal of mucus and some blood are mixed with serum, we may suspect parenchymatous enteritis; if the serous membrane alone enters into the state of acute inflammation, frequently transudation takes place on its free surface.

I have seen cases of profuse serous discharge, in a very short time, even in less than twenty-four hours, produce collapse and death, and in some of these instances necroscopy could not discover an adequate alteration either in the mucous or in the serous membrane.

The serous species of discharge is frequently merely a product of sympathetic secretion. I observed it sometimes connected with large transudations in the chest, and with chronic hydrocephalus.

Speaking in general, serous diarrhœa, if even arising from rheumatism, is more difficult to manage than the mucous. Very minute doses of calomel, with Dover's powder and mustard poultices, are frequently beneficial.

Pure serum, like rice-water, is a less favourable quality than the dirty white or yellowish. Dark-brown serum frequently denotes a disorder in the portal system, present in some severe gastric or typhoid fevers, but I have seen a similar quality also in chronic affections of the brain, and very frequently in scrofulo-impetiginous children. This is worthy our attention, in particular if eczema or impetigo has disappeared from the head and face. This brown and fœtid discharge accompanies sometimes the commencement of chronic hydrocephalus. I treated it successfully, in this last case, with high but very diluted doses of iodide of potash.

4. *The green bilious discharge*. If pure bile, then the voided matter is in general not abundant; in young children it is of a more yellowish than green colour. The essential character of bile is, to be *of a greenish colour* (in infants it is voided green) *at the very moment of its evacuation*. This kind of discharge is very frequently present in acute inflammatory and febrile affections; if dependent upon an affection of the brain, then we may find the colour to be rather brown, and the abdomen retracted. If a similar source produces abundant serous bilious discharges, then we find the abdomen much collapsed. But I must observe, acute affections of the brain are almost always connected with constipation, only in some cases of chronic hydrocephalus I met with the mentioned diarrhœa. Bilious discharge, as arising from bilious fever, or from derangement of the liver, is rare in young children. In this case the right hypochondrium will be more or less bloated up. We must be careful not to confound the green bilious discharge with the following:

5. The *discharge, like chopped eggs*, mixed with mucus, some clots of bile, and caseous coagula of indigested milk, or other kind of food, accompanied almost always by gripes and flatulence; its smell is disagreeably acid, and the whole matter, some minutes after being discharged and *exposed to the atmosphere, becomes green*. We know not exactly the chemical change which produces this colouration; it seems to be an oxydation of some of the elements. Then the essential character of this discharge is, that it is yellow at first, and becomes green by exposure to the atmosphere, whilst bile is green at the moment it comes out. I shall call this *the acid saburral discharge*, which is the most obvious before the sixth month of age, in particular if the sucking child takes, besides the milk, some farinaceous food. Practitioners commonly prescribe in this case rhubarb, with magnesia. For my part I prefer, in tender infants, to rely more upon a convenient change in the diet, and, as a remedy, aromatic frictions of the epigastrium, and internally bicarbonate of soda, dissolved in mint water.

6. The *bloody discharge*. Pure red blood is seldom discharged by children; in some rare cases I have seen half or one tablespoonful come out, as the product of active congestion and hæmorrhage. Very frequently, on the contrary, blood is combined with the mucous discharge; and in this case, if it is preceded by pain, without tenderness, it denotes an inflammation in the upper parts of the intestinal tube, at least not near the rectum. Tenesmus signifies that the seat of the inflammation is in the lower parts of the colon, or in the rectum. This form is commonly called *dysentery*, not dangerous, if it is without bilious complication and fever, and if treated in its early stage with Dover's powder, some doses of castor oil, and warm poultices; in a stronger degree, leeches at the anus; but if neglected in the commencement, it becomes dangerous to the life of the child. Professor Rokitansky of Vienna describes most exactly what he calls the "dysenteric process," in three gradual degrees of anatomical change. The highest degree, presenting a dirty red and gray marbled surface, with considerable thickening, granulation, and ulceration, I never saw in the tender age. Young children die before this stage is developed.

Passive hæmorrhage of the intestines very seldom occurs in children. I have seen, however, some cases where, without adequate pain, a considerable quantity of dark thin blood was discharged. Lastly, I have seen a case in a child six years old, where, during the course of a gastro-typhoid fever, more than one pint of carbonized blood was discharged in two days. The case recovered. The boy is affected with an enlarged spleen.

Moderate quantities of red blood, discharged without pain, frequently occur, mixed with mucus, and are, without signification, sometimes even connected with the advance of recovery from gastric affections. This is the same case as with epistaxis.

Golding Bird and Simon state, as the result of chemical analysis, that some dark-green stools of children owe this colour to blood which has suffered a certain chemical change; but those chemical inquiries are not yet arrived at a satisfactory exactness; we do not even know exactly what kind of green discharges were the subject of these inquiries.

7. *Calomel stools*. Green, more or less thick, or mixed with serum, and in this case more abundant, produced by full doses of calomel. Calomel stools resemble bile, and contain much bile, but they contain also some particular chemical elements which we do not exactly know. In many instances it happens that the calomel diarrhœa commences some days or weeks after the use of mercury, and we must be aware of this, and not confound it with the primary bilious discharge. In the former case the region of the liver is in general softer than in the latter. A clever practitioner will never try to stop directly, and with astringents, a green discharge, whatever be its origin and nature.

Calomel stools sometimes contain blood. After what I have seen in dissection, I incline to attribute this circumstance to a sub-inflammatory state, with superficial erosions of the mucous membrane, which sometimes take place in children after the continued use of calomel.—*Prov. Jour.*

REVIEWS AND NOTICES OF BOOKS.

VARICOSE VEINS AND VARICOSE ULCERS. By Thomas W. Nunn, Surgeon to the Western Dispensary, &c. &c. London. 1852. 12mo. pp. 63.

An outline of this essay originally appeared in the pages of the *Medical Times;* "subsequent experience and observation have enabled him (the author states) to enlarge upon the details of the leading questions contained therein, and justify his more formally committing himself to the views then advanced."

Mr. Nunn commences by calling attention to certain points connected with the anatomy and functions of the superficial veins. "Those veins commonly classed as subcutaneous in the limbs, consist in reality (he observes) of two sets. One comprises those which are supplementary to the deeply-seated vessels, and which occupy an important relation to them. The other includes those especially belonging to the integuments; that is to say, to the skin, fat, and cellular tissue."

"The former set, or supplemental veins, are distinguished by the great strength of their walls; they pursue a direct course towards the centre of circulation, lie close upon the aponeurotic investing membrane of the limb, and are bound down, or, as it were, woven on to it by a fibrous expansion of greater or less strength and extent.

The latter, the integumental veins, are remarkable for their thin semi-transparent walls; are of much smaller calibre, but are far more numerous, being spread over the whole surface; have frequent communication with each other, and lie almost immediately beneath the cutis, and therefore on a plane external to the first named set, into which, however, they eventually pour their contents."

The relations of these two sets of veins to one another may be demonstrated (the author observes) by choosing for dissection a limb that is very œdematous; "the integumental veins rise with the skin, and are thus separated from the others which are retained against the fascia lata by the fibrous expansion covering them."

The pathology of varicose veins and the changes in the skin dependent thereon, occupy the next section. "Varicosity consists essentially (the author observes) in an enlargement from a special cause of the veins of a part, not coincident with either a healthy or unhealthy increased arterial supply, the capacity of the veins ceasing to bear the normal ratio to the capacity of the arteries."

Mr. Nunn arranges the different forms of varix under three heads:—

"1. Simple dilatation.

2. Dilatation with attenuation of the walls of the vein.

3. Dilatation accompanied by thickening and hardening of the walls of the vein.

In the first, there is the fact of vessels enlarged and tortuous, but otherwise healthy.

In the second, there is a deficiency of nutrition, or further, the occurrence of absorption.

In the third, there is a complication, from the advent of inflammation, acute or subacute, according to circumstances."

The tortuosity of varicose veins is accounted for as follows:—"Fluids press equally in all directions, and therefore the increase in the length of the veins must progress in a certain ratio to the increase in diameter, proportionate to the difference between the resisting forces offered respectively in each direction. The tortuosities are the natural result of the lengthening. They result from the accommodation of the stretched vessel to a space originally provided for one of a half or a third its length, as the case may be." "When the vein is bound on to the fascia lata by a strong aponeurotic layer, it cannot become tortuous for obvious reasons; and thus tortuosities are only found where this binding down does not obtain."

The changes which take place in the skin, previous to the formation of an ulcer, are next very accurately described. We cannot follow the author through this part, and shall confine ourselves to an extract from the concluding portion of the chapter:—

"The varicose ulcer, viewed as the result of a more intense degree of the inflammatory process already existing in the tissue in which it occurs, may be easily conceived to be originated in a variety of ways. Nevertheless, considerable trouble appears to have been taken to give an accurate account of the precise commencement of the ulcer. Practically, this is a matter of no moment whatever; while, viewed as a question of pathology, it may be said to require a different solution in almost every individual case. A varicose ulcer may follow the giving way of a vein, or even a simple scratch. It sometimes begins as a black spot, sometimes as a whitish patch.

The varicose ulcer is always found below the knee. It is usually irregularly shaped; its edges are thickened, and not of a constant colour; the neighbouring tissues are indurated, leaden to the touch and eye. The granulations vary in appearance; sometimes of bright red, sometimes dull red, or dull red mixed with yellow; the condition of the ulcer in this respect depending on the intensity of the inflammatory process, and upon its complicity with other affections of the general system."

The third section is devoted to the treatment of varicose veins and varicose ulcers. Mr. Nunn is an advocate for the use of the elastic band, with a pad adapted to press upon the vein. "If the walls of the vein be pressed against each other, no blood can pass (the author observes) either in an upward or downward direction, and the vein is as completely closed as though a ligature had been placed around it. By the application of pads, fitted with elastic bands, by which continuous compression may be maintained, all the advantages of what has been called the radical cure may be obtained without any of the danger attendant on that proceeding."

"The pads should be made of soft elastic wool, and the compressing band must be between three and four inches broad. Vulcanized India-rubber, one-twelfth of an inch thick, or a woven texture into which this substance is introduced, forms the best material for the construction of these bands, light buckles and straps being fitted for the purpose of regulating the pressure. According to the nature of the case, the number and size of pads must be determined. One placed just below the knee usually suffices. It is advisable to remove the bands on going to bed, taking care to replace them before the upright posture be reassumed."

We look upon Mr. Nunn's essay as a very useful contribution to the stock of information which we possess upon the subject; and we think it may be consulted with advantage by every one who is called upon to treat those common and often troublesome affections.

ON MALARIOUS POISONS.

The following is an extract from a paper on this subject by Dr. Johnson, read at the monthly meeting of the Literary and Scientific Institution of Kilkenny, March, 1852:—

"Some consider it strange to hear a medical man advocating sanitary improvement. Medical men have always advocated it; and this, I believe, has aroused the suspicions of superficial thinkers as to its expediency. Either, say they, the doctors cannot be sincere, or these doctrines cannot be for our welfare. Arguing on the inherent selfishness of human nature, they adroitly conclude that doctors are no better than themselves; as soon would they expect to hear the doctor tell them to 'throw physic to the dogs,' as hear him advocate the public health. Banish disease, say they, and then 'Othello's occupation's gone.' To such a one my answer simply is—'Mendose colligis;' from false premises you draw a false conclusion. I can show you that sanitary measures are quite consistent with the doctor's interests. This may appear startling, but so it is. He has no right to lay claim to disinterestedness for their advocacy. The diseases most useful to the doctor will never be eradicated by sanitary measures; they are the consequences of your own frailties, your vices, indiscretions, and over-indulgence. Such are gout, dyspepsia, gastritis, scrofula, and a host of others too numerous to mention. It is the fearful epidemic scourges to which every community is subject, and which depend on the development of miasmatic agents, that can alone be arrested by sanitary precautions; but these increase vastly

the risk and labours of the medical officer, with little or no increase to his emolument. They prevail chiefly among the poor. The comparatively rare cases which occur among the wealthy are no offset to the increased labour and vastly increased risk which he incurs. His public duties are enormously increased, but his public salary, which is always fixed at a minimum, never alters: no sliding scale proportions it to his duties. The years 1846 and 1847 can tell a fearful tale of widowed matrons and helpless orphans. It was ascertained by a rigid statistical inquiry, that in Ireland alone in one year five hundred medical practitioners succumbed to miasmatic disease, of whom very nearly two hundred fell nobly at their posts; whilst it was found by another accurate calculation that in one fatal season the mortality in the medical profession was greater in its proportion than the average deaths of military officers killed in action. And recollect that death has little terror for the medical officer compared with the dreadful prospect of leaving a beloved wife and endeared, but helpless progeny, destitute and forlorn—since forlorn they will surely be unless endowed with this world's goods. The medical man generally dies young, and is too often forced by public opinion to marry young, and under circumstances usually esteemed imprudent. Out of 443 medical practitioners who died between 1843 and 1st of January, 1848, 74 died between 26 and 30; 39 between 30 and 35; 73 between 36 and 40; 37 between 40 and 45; 57 between 46 and 50. In 1847 nearly 200 died of the prevailing epidemic. Supposing an average of five children to each family—and this would be a safe calculation—we have in one year 200 widows and 1000 orphans left to buffet the ruthless waves of a cold and selfish world. Is it any wonder now, I ask you, that medical men are among the advocates of sanitary improvement? I have said thus much partly to exonerate my noble profession—partly to disabuse the public mind. For my observations to-night I selected a subject deserving of more attention than it obtains. I should not regret having done so if my imperfect remarks could awake in the public of Kilkenny an interest in sanitary improvement, in which they are lamentably deficient. Were the maxim better realized, 'Salus populi suprema lex,' not only would the rich and poor be benefited, but the doctors themselves would derive a great advantage."

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, APRIL 14, 1852.

OPERATION OF THE DISPENSARY ACT.

It is not because we are unacquainted with the state of anxiety and suspense which prevails throughout the ranks of our profession in Ireland at the present moment, neither is it because we do not sympathize with our brethren in their difficulties, that our columns just now are sometimes devoid of that energetic tone which the occasion may appear to require. It is because the existing critical state of affairs calls for a very prudent exercise of our editorial functions, and a very careful consideration of the policy which results may suggest. Of the tangible grievances of individuals, there is an abundance demanding special notice; but in dealing with such, a risk of interference with the interests of others is incurred which calls for reserve. In many cases the new Committees of the new Dispensaries are acting unjustly and partially in the selection of Surgeons, but it would prove a very invidious task indeed for us to pronounce upon the claims of conflicting candidates. Within a very short distance of the place from whence we write, a case of great hardship has occurred, and yet we are disabled from contributing to relief from it by such considerations. A practitioner of the greatest respectability, for thirty years attendant to the oldest dispensary in the district, is set aside by the committee, and a gentleman many years his junior, with much weaker legal claims, is put in his place; yet we are disabled from doing more than protesting against such a proceeding. The successful candidate is, we believe, a respectable practitioner, and well qualified to fill such a situation, and we therefore cannot suggest his exclusion; but we must express our regret that the new law admits of such a flagrant abuse of power. That such a misapplication of its provisions never was contemplated by its framers, we are convinced; on the contrary, a power is conferred by it on the Commissioners to prevent any such perversion of its objects; yet we cannot well insist upon the exercise by them of this power, seeing that by so doing we should espouse the cause of one of two contending parties. We are also constrained to observe a prudent reserve respecting the present proceedings of these new committees, lest we should be the means of embroiling candidates with them who are still at their mercy: nothing irritates such people more than the strictures of the press, and, being irritated, nothing restrains them in their anger. In fact, we wait until the system contemplated by the act is fairly in operation, and then we hope to aid in its salutary application. We have said before, that this measure being now an accomplished fact, we are bound to promote its useful application, whatever doubts we may entertain as to the necessity for its enactment, or the means by which it was called into existence. It is vain to deny that much dissatisfaction prevails as to its defects in working properties, and that loud complaints are made against those entrusted with its execution, on account of some of the results of its operation; but it is impossible now to call for its abrogation. It is also obvious that an inclination prevails to attribute the defects in its operation to a want of decision on the part of one more than another of those entrusted with its execution, but this view we cannot take. We hold all the Commissioners equally responsible for its results, not excepting the two who *ex officio* sit on the Board; indeed, we hold the Chief and Under Secretaries for Ireland to be most answerable for consequences, bound as they are to handle the matter as statesmen, and being more tangible in parliament. As to making any one of the Commissioners scape-goat for the rest, we cannot hear of any such thing; nothing could be done more calculated to encourage slovenly or sinister practices. When, therefore, we express an opinion as to the maladministration of the law, it must be clearly understood that we do not lay such a charge at the door of one more than another. The principal causes of complaint appear to be, inadequate salaries, excessive size of districts, and the labour of keeping the books. The two former must be removed when proved by the Inspectors to be well founded; and the latter must be at least diminished by modification. If the low salaries and excessive duty assigned in some unions be continued, it is obvious that the Surgeons so treated cannot continue to hold the situations; indeed we hear already of many resignations, and of many more in contemplation. In this event, persons of an inferior class will perhaps accept the vacant situations, as they did in England under similar circumstances, and thus will our profession be utterly degraded in Ireland. That parsimonious Guardians would prefer "medical officers" of a low grade, there can be no doubt; but that the Commissioners would sanction such policy we cannot believe, and the sooner they say so the better. The hospital and dispensary statutes of Ireland declare that these institutions are to be attended by either Physicians or Surgeons, and any evasion of the law and practice in this respect must be resisted. In Ireland we know nothing of "medical men," "medical

officers," "general practitioners," or any other hybrid; and any attempt to smuggle such into existence will, we hope, meet with the resistance which such a proceeding deserves. Above all things, any attempt to place the holder of a sham diploma on a level with the regular Surgeon cannot be tolerated. We say this much because the Commissioners in England, when baffled in their attempts to compel the Surgeons there to accept a low rate of remuneration, endeavoured to substitute unqualified persons for them. It may be, that in glancing at this possible erroneous exercise of authority, we anticipate what is not in contemplation; but seeing the efforts now making to prop up decaying institutions by the gratuitous issue of sham qualifications, we think it expedient to interpose. Indeed, we deny altogether the right or power of any board, or other authority, to dispense with the regular qualifications provided by royal charters and statutes for establishing the eligibility of Surgeons for public office, on the ground that a clause in an act of parliament gives general powers to make rules or to declare qualifications. When the heads of departments, civil or military, are so empowered, it is obviously to restrain subordinate parties from appointing unqualified persons. They are to enforce laws and establish salutary usages, not to assume the functions of legislators; and any departure from such a rule of practice will be a usurpation of the functions of the Colleges of Surgeons.

THE PHARMACY QUESTION.

We have not for some time been called on to continue our comments on this subject, but the introduction of a bill into parliament affecting it, of which we here give a sketch, makes an allusion necessary. It is not probable that such a measure will pass during this brief session, but sooner or later something of the kind must be adopted. The legitimate practice of pharmacy unconnected with medical practice, abandoned by the apothecaries, has virtually passed into the hands of compounding chemists, and regulations for the control of that body have consequently become necessary. It matters little whether the Apothecaries' Companies have acted wisely or not in deserting the position assigned them; the safety of the public and the interests of Physicians and Surgeons call for a functionary who devotes himself exclusively to practical pharmacy. The London Apothecaries' Company, we perceive, have cast off all connexion with the "art and mystery." They now announce that the recipients of their diplomas "have passed their examinations in the science and practice of medicine," and the "heads" of the Dublin Hall, who profess to be "General Practitioners," are equally determined to manufacture "doctors." and not apothecaries :—

From the discussion in the House of Commons on the second reading of the Pharmacy Bill, it is obvious that the object of the bill is not clearly understood. With a view of removing any ambiguity which may exist in the terms of the bill it may be well to state briefly its intended operation in relation to the several classes of persons to whom it refers—namely, Medical practitioners, exempted from all interference, clause 20. Medical practitioners in business as chemists and druggists before the passing of the act, may at their option continue as before without interference, or if they relinquish the medical profession may be registered as pharmaceutical chemists. Members of the Pharmaceutical Society, original members (including associates), examined members, registered as pharmaceutical chemists, clause 9. Recognized chemists and druggists, not members, registered as pharmaceutical chemists, clause 9, on application and the production of evidence within a year of the passing of the act. Assistants and apprentices, to be registered, clause 10. Recognized chemists and druggists neglecting to register, also persons acting as chemists and druggists, but having no pretensions to a qualification, and not producing the required evidence, not registered, but exempted as persons in business before the act, the *onus probandi* resting on themselves, clause 15, lines 3 and 4. Grocers and small shopkeepers, who sell a few common drugs, not affected by the act, unless they pretend to be chemists and druggists. Future pharmaceutical chemists, examined and registered, clause 13. The public, at liberty to buy medicines where they think proper, but protected from imposition on the part of persons pretending to be what they are not. From this brief analysis of the bill, it will be seen that it is not calculated to injure any class, that it does not create a monopoly or interfere with free trade. Vested interests are protected, qualification is established and recognized, imposition is prevented, and the register forms a line of separation between medical practitioners and chemists on one side, and between chemists and unqualified persons on the other. The idea of Mr. Bouverie, that it is intended to convert chemists into medical practitioners, is proved to be erroneous by the words of the act, and by the explanation of its provisions to which his remarks were intended as a reply. His other inference—namely, that it is intended to raise a large revenue from chemists already in business is equally fallacious, as the act provides that all such persons are to be registered at their option, "without the payment of any fee." They will not be obliged to subscribe to the Pharmaceutical Society. On the contrary, they can only be admitted by election, according to the provisions of the charter. Those who become members will have a voice in the election of officers and the management of the Society, and will pay the subscription in common with other members. All parties, whether members or not, will be left in the undisturbed enjoyment of their existing independence and privileges as fully and amply as if the act had never been passed. The question of money has always been dealt with as a secondary consideration—as a means to obtain an end. Without the sinews of war nothing can be done, and all that is wanted is enough to defray the necessary expenses of maintaining the institution in a creditable and effective manner. It will be for the committee of the House of Commons to decide what provisions are to be made for this purpose, and what limits are to be placed on the powers of the Society. The salutary effect of the act will be gradual. No act of parliament could bring about a sudden revolution in the qualifications of a numerous and heterogenous class of persons. If all the present race of chemists were as highly educated as they ought to be, an act would be unnecessary. Such as they are they have a claim to be taken as the nucleus on which the improvement is to be founded, while at the same time justice requires that all vested interests should be protected. This was the case with the original physicians, the barber surgeons, and the "apothecaries before the act of 1815." Each of these bodies was characterised, in the first instance, by those imperfections which are inseparable from new institutions, but which, by the influence of legislation on the rising members, were gradually removed. The same result may be calculated on in the present instance. As each registered "chemist before the act" dies, or retires from business, his place will be filled by a successor who has passed the examination. Among those who are now preparing themselves for examination, some will, in process of time, become examiners, others will become teachers in the schools of chemistry and pharmacy, which the demand for education will call into existence. The attention of the entire body being directed to the progress of science and the march of education, all will find it their interest to keep pace with the times and to use such means as may be accessible for increasing their knowledge of the business. Thus a general improvement will be the result, and this will be no less creditable to the chemists themselves than beneficial to the public. We have stated that the complete reformation will of necessity be a work of time, probably from ten to twenty years. This, however, is no argument against the bill. An interval must of necessity elapse between the time of sowing the seeds of pharmaceutical education and the maturity of the crop of qualified pharmaceutical chemists. Much advantage will arise from the investigation of the subject before a select committee of the House of Commons. Very little is known in that assembly respecting the constitution and proceedings of the Pharmaceutical Society, and when we consider how liable corporate bodies are to a variety of abuses, and the disposition which too often prevails to take improper advantage of irresponsible powers, it is not surprising that hesitation should be felt in enlarging the powers of an institution

without a due inquiry into its objects, tendency, and all the circumstances connected with it. At the time the Pharmaceutical Society was founded, every precaution was taken to guard against abuses, and to avoid the errors into which other societies had fallen. Being designed as a means of ultimately uniting the entire body of chemists and druggists for the purposes of education, examination, and registration; and being formed not merely for the present time, but for the future promotion and regulation of pharmacy in this country, it was necessary so to frame the constitution, that no mistake could hereafter arise respecting the objects of the Society, and the powers which it was intended to possess. An act of parliament is the ultimatum which has always been in prospect as the only means by which permanence could be given to an organization of chemists and druggists for the regulation of the affairs of that body, and the advancement of the art and science of pharmacy. After eleven years' experience in the practical working of the machinery created for the above purposes on the voluntary principle, a report before the committee, of these proceedings and the result, will furnish tangible data, which did not previously exist, and which could not have been obtained except by actual experiment. The claim for an act of parliament rests therefore, not on hypothesis, but on facts, and whatever may be found defective in the charter can be rectified by the act. Several amendments have been suggested which will be duly considered, and in the investigation of the committee the primary objects of the Society will be kept in view—namely, the benefit to the public by the security which the improved education will afford, and the advantage to the chemists themselves by their union and future recognition as an educated body.—*Ph. Jr.*

ENGLISH NOTIONS ABOUT TRINITY COLLEGE.

Although we do not take exactly the same view of the writer of the following note respecting the cause of the lamentable decay of the Medical School of our elder University, we copy it to prove that we are not singular in our "notions" respecting the matter. The fault of Elizabeth's provision for the education of her Irish subjects is not, however, an over stringent discipline, or a very rigid adherence to the letter of statutes; on the contrary, we believe that the present policy is to "make it easy" for aspirants to medical honours. The degree of A.B. is, we hear, just now to be had on terms somewhat less irksome than the same degree as taken by general students, in case the candidate proposes to addict himself to medical pursuits; so much so, that grave doubts are entertained as to the true academic value of the "doctor's" credentials, as compared with those of other graduates:—

I would beg through the medium of your valuable journal to put the following question:—What has the Dublin University done for medical science, or of what use is it to Irish medical students? I am induced to put this question from observing that on the last great day for conferring degrees (Shrove Tuesday), not a single medical degree was conferred. There were certainly two M.D's put on Bachelors of some ten years' standing; but I say emphatically, that out of a class of medical students in Dublin, to the amount of some 800, not a solitary example of M.B. was to be found. Why is this? I believe the truth is, the course of education in Trinity College is loathsome in their eyes, and perhaps justly so. There is a want of respect, as well as impartiality, on the part of the fellows towards the students; besides, the physical and ethical course is excessively severe—a student is kept two whole years in Locke and logic, along with the other courses, subjects of little importance to students of our profession. You are aware the B.A. must first be obtained. I think the day must come to exclude this law from universities; it only exists in one or two now; and certainly the most eminent medical men in Dublin never even entered T.C.D., the majority of whom are graduates of the Scotch universities, proving that A.B is not essential to eminence, at least in our profession. The Queen's University does not require it, neither does the London University; but, sir, the degree of M B. appears to me a very absurd title altogether. Why not establish at once an M.D., and no more about it? The nonsense of first one, and then another, &c. &c., as in Dublin University, is, that here you must take no less than four degrees to be M.D.—viz., A.B., M.B., A.M., M.D.! with proportional times and payments; three years here, four years there; here a little, there a little. Such is a medical student's prospects in the Dublin University—the Irish national university, that about *ten* years will complete the time for an M.D. It is a matter of deep regret to the students; but what can they do? The charter must be altered, or the by-laws less stringent.—*Letter in Lancet.*

ETIQUETTE OF CONSULTATION.

In our last we gave a correspondence practically illustrating this chapter of medical law, and we here add the comments of a contemporary for the instruction of our readers as to the notions entertained on the subject on the other side of the water. With us we believe such professional coöperative proceedings go on smoothly enough. The hostility of certain pure Physicians to Surgeons is marvellously neutralized by an invitation to a consultation, and those "called in" by the apothecaries know their duty too well to cause any unpleasant difference of opinion. We find a letter from Dr. Ranking on the subject in the last *Lancet*, which we propose to copy in our next:—

The correspondence respecting the etiquette of consultation, published in our last, involves a question of considerable importance to the convenience and efficiency of formal professional intercourse. We must, however, regret that such an angry tone was imparted to a correspondence which, as no ill motive was assigned on either side, might have been carried on upon terms of perfect courtesy. It seemed evident enough that Dr. Ranking had no hostile feeling whatever, nor any motive of a censurable kind, in returning to the chamber of the patient after Mr. Howard had left the house. No imputation of currying favour, or lessening the proper professional consequence of the ordinary medical attendant, can rest on Dr. Ranking. Still we think Mr. Howard was right in maintaining the absolute integrity and sacredness of consultation, and that Dr. Ranking was wrong in the view he took; and we lament that mutual explanations should not have taken place of a satisfactory character between two men of such undoubted honour and integrity. The rule adopted in London at the present time, founded, we believe, upon the invariable practice of Dr. Baillie, is, that the ordinary medical attendant should precede the physician or surgeon called in consultation on entering the sick chamber, and follow them on withdrawing from it. If a third or fourth opinion should be called in, the same rule is observed: the last summoned entering last, and going out first. This form has some obvious conveniences, and prevents even the suspicion or possibility of unfairness towards those who were first in attendance upon the case. So, on the recovery of a patient, when several physicians and surgeons have met, those summoned latest to the case are dismissed first from the attendance, so as to leave the case at the termination in the hands of those first in attendance. We have taken this occasion to advert to these matters, convinced as we are that attendance, even to the minutiæ of etiquette, is the most certain means of preserving those professional confidences and amenities, without which the practice of medicine would be surrounded by difficulties and causes for disagreement.—*Lancet.*

RIGHTS OF NAVY SURGEONS.

The Belfast Medical Society, at their monthly meeting on Monday evening, the 5th inst., appointed a deputation to wait on the different candidates who may come forward to represent the borough of Belfast in parliament, to urge upon them to support the claims of assistant-surgeons in the navy to secure their just rights; in which struggle, all medical men should join.

To Correspondents.—The letter of Mr. Halpin of Cavan arrived too late for notice in this day's publication.

APPOINTMENTS.

Henry Thompson, M.D., of Omagh, has been appointed Visiting Physician to the Omagh District Lunatic Asylum.

Philip N. Walsh, M.D., has been appointed Medical Officer of the Walshtown Dispensary District, in the Middleton Union, county Cork (a district newly formed under the Medical Charities Act).

THE PHARMACEUTICAL JOURNAL, APRIL 1,

CONTAINING THE TRANSACTIONS OF THE PHARMACEUTICAL SOCIETY.

CONTENTS—The Principle of the Pharmacy Bill—Fraud and Quackery—Bicarbonate of Ammonia—Liquid Socotrine Aloes—Miraculous Berry of Western Africa *(with cut)*—Optical Properties of a New Salt of Quinine *(with cuts)*—M. Soleil's Polariscope for Determining the Quantity of Sugar in a Solution *(with cuts)*—The Soda Phosphate of Iron—On Aloine—The Purity of Sulphate of Quinine—Iodide of Starch—Method of Detecting Traces of Phosphoric Acid—Decolorizing Properties of Charcoal, &c.—The Distillation of Cloves—Oil of Cloves—Centrifugal Glass-Blowing Machine—Meat Biscuit—Adulteration of Borax—House of Commons—The Pharmacy Bill, Second Reading—Select Committee on the Bill, &c. &c. THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishment are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, *Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.*

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT AT

G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that on the 2nd of August, 1852, the Council will proceed to elect a Curator of the Museum from among the Fellows or Licentiates of the College.

Candidates will be required to lodge at the College on or before the 24th of July next, such Preparations, in Human and Comparative Anatomy, made by themselves, as they may consider best calculated to demonstrate their skill and abilities.

Information respecting the emoluments and duties of the office may be obtained by application to the Registrar at the College.

By order of the Council,

H. MAUNSELL, Secretary.

Dublin, April 2, 1852.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that on Tuesday, the 4th of May next, at the hour of Two o'Clock, the President and Council will proceed, according to the provisions of the Supplemental Charter, to elect, from among the Fellows of the College,

Three Examiners in Medicine and Surgery;

Two Examiners in Anatomy and Physiology;

One Examiner in Materia Medica, Chemistry, and Medical Jurisprudence;

One Examiner in Midwifery.

Candidates are requested to lodge their applications at the College on or before Thursday, the 29th of April.

By order of the Council,

H. MAUNSELL, Secretary.

Dublin, April 2, 1852.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Twelve months,	...	...	...	...	£1 5 0
Six months,	...	...	...	...	13 0
Three months,	...	...	...	...	6 6

*** Orders to be addressed to Mr. HENRY BEAUMONT, 15, Molesworth-street.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Wednesday, April 14, 1852.
